A Preliminary Report on the Rollier Treatment of So-Called Surgical Tuberculosis.—Dr. JOHN H. PRYOR of Buffalo said that tuberculous lesions by an arbitrary custom when located elsewhere than in the respiratory tract had been grouped and defined quite unreasonably as belonging to the field of surgical tuberculosis and this led to unnecessary operating or other forms of surgical interference with unsatisfactory or disappointing results. This had directed attention to local rather than constitution conditions and led to a disregard of common sense agencies. That there was a genuine need for surgical relief which must be invoked at times was appreciated, but the operation should be superceded or followed by other beneficent influences. Dr. Pryor reviewed the history of heliotherapy and made a report of the work of Rollier at Leysin, showing that he claimed more than 80 per cent. of recoveries in closed cases and over 70 per cent. in open cases. Rollier had treated during the period 1905-1913, 1,129 cases. Rollier asserted that 308 of these recoveries were associated with motion of previously affected joints. The important features of Rollier's method were that the insolation was very gradual and slowly completed. The diseased part was kept covered and only exposed to the sun after the coat of tan was existent over the rest of the body. The patient was accustomed to open air life and sleeping out of doors for about one week. During this period the temperature, pulse, respiration and the results of urinary and blood examlinations were recorded. Preparation for the sun bath included protection from wind and draft. The head was protected by a linen cap or a small awning at the head of the bed. Very gradually by exposing a small portion of the body at one time, the entnre body and finally the diseased part was exposed and tanned as deeply as possible. After each insolation the patient was rubbed with spirits of camphor with a rough glove. Ultimately the insolation was practiced four to six hours every day. This treatment was all carreid out on a bed to secure convenience and control. Caution must be observed to prevent sunburns and dermatitis. Reactions might occur if the exposure was pushed too rapidly. During the summer the children well tanned could walk and play most of the day unclothed except for a loin cloth. The skin became a bronze hue and then a copper color and finally a chocolate brown which signified intensive pigmentation. Those who had visited Leysin reported that Rollier's claims were justified and his report of results not exaggerated. The Rollier treatment was first introduced in this country at Perrysburg, N. Y. The site was 1650 above sea level with plenty of woods for wind protection. Experiments with this treatment was begun in 1913 with a few patients suffering from tuberculosis of the bones or glands. The buildings were planned for open air life day and night with protection from and exposure to the sun. The child was naked except for a loin cloth, a cap, and slippers, with stockings in the winter. In the winter time the children were permitted such games as snow shoeing, tobogganing and sleighing. Pictures were shown of the children who had played one hour unclothed in the snow. This freedom was only allowed after months of exposure and gradual hardening. The children thus had exercise, games, and open air schools. They had demonstrated that they could pursue the same methods as Rollier described without any risk or danger in this climate. The exposed children developed marked resistance to cold and its consequences. As the treatment progressed practically every child showed an increase of hemoglobin and red cells. Colorado, New Mexico, and Arizona seemed to have an ideal climate for heliotherapy, but the climate of Switzerland was not a sunny climate and they had shown that good results could be obtained in localities with somewhat unfavorable weather conditions. The duration of the treatment was long and a large number of tuberculous dependents could not be sent away and were forced to be cared for at home, but the results justified resignation and patience. At the present time 65 patients were undergoing treatment in strict accord with Rollier's method. Of these, 47 were children under 15 years of age. Ten had pulmonary tuberculosis but there existed other manifestations as bone or gland involvement. It had been found that the complications disappeared rapidly under the sun treatment. All the patients at the hospital were improving in various ways which had not been apparent with open air treatment alone as was shown by better nutrition, increase in weight, the subsidence of the fever, the return to normal blood count and a subsidence of active inflammatory conditions. Motion returned in cases in which it had been entirely unexpected. The results seemed so remarkable that they justified incredulity until one had seen and was convinced. Thus far Rollier's astonishing statements had been proven true.

Dr. HORACE LOGRASSO showed moving pictures of life at the Adam Hospital, the buildings, the method of applying the treatment, the unclothed children playing in the snow, the open air school, the outdoor life in many phases.

Dr. CLARENCE L. HYDE of Perrysburg emphasized the fact that they were very careful about exposing the children in the winter. They were especially careful to protect them from the wind and from chilling. Perhaps they did not realize how warm the sun was, even in the winter; one of the children was sunburned on February 2, when the pictures were taken. In treating the fistulas and sinuses they used no antiseptic dressing, but simply covered them with gauze so that they had the benefit of the sunlight and air.

Dr. ALBERT HENRY GARVIN of Raybrook said that while there had been a great deal of interest in providing for the care of tuberculous adults, that there had been no provision made for children under the age of fifteen years. Of course, it was proper that they should not be mixed with adults as their requirements in the way of treatment were different. If, as was often stated, the genesis of tuberculosis in the adult was based on an infection in childhood, then if they would combat the disease successfully they must prevent tuberculosis in childhood.

Nuts and Fruits: Their Value in the Diet of Children.—Dr. GEORGE DOW SCOTT of New York said that among the laity there was a firm conviction that nuts gave rise to indigestion and fruits caused hyperacidity. To some the knowledge that nuts were highly nutritious was new.

Nuts, however, contained water, protein, fat, sugar, starch, crude fiber, and ash in large proportions. Each kind of nut had its particular caloric value. Dry nuts were very high in nutritive value and contained more fat than any vegetable substance known. In nutritive value nut butters were far above ordinary cream butter. Dr. Scott had given nuts to children as a substitute for meat because of the nutritive value in intestinal fermentation. The discomfort of eating nuts was due to faulty mastication and to the erroneous habit of giving them to children after a hearty meal, between meals, or late at night, whereas they should form an integral part of the meal. Probably nut protein was not as easily digested as meat protein on account of the water content of 3 to 5 per cent. in nuts against 50 to 70 per cent. in meats. It was, therefore, fair to assume that the finer nuts were divided, chopped and mashed, the more rapid would be their digestibility. Salt did not make nut food more digestible. Mothers should understand the food value of nuts better, giving a variety of nuts to suit the individual child, but it must be understood that they were given as an addition to the diet. After weaning the child, nut butter should be cautiously given. Such butters should be more carefully prepared than those for older children. The nut kernels were pounded in a nut mill until of a thick, creamy consistency, and strained through two layers of clean boiled muslin or fine wire sieve. Fruit juice or finely cut or mashed fruit should be added. The stools should then be watched for undigested particles of nuts or any chemical disarrangement as diarrhea, duodenitis, or enterocolitis. If the butter agreed, the quantity should be gradually increased, care being taken to avoid overtaxing the child's stomach or digestive capacity. In the constipation of infants, nuts formed a valuable aid as a lubricant on account of their oils, but they acted as irritants because of the large amount of refuse which they left. Fruits were given to infants because they were palatable, refreshing, nutritive, and because of their salts, their diuretic, laxative, tonic and antiscorbutic action. In scurvy and other digestive conditions, the fruit juices were almost a panacea on account of their antiscorbutic qualities. In conclusion, Dr. Scott said that the nutritive qualities of fruits and nuts were not to be deprecated; the foods were not to be given to the child as a pleasurable and luscious appetizer only, but as a food in addition to the general diet, stimulating, nourishing, and exhilarating it to a stronger mental and physical existence. Dr. Scott presented tables showing the percentages of food elements in the different varieties of nuts and foods made from nuts and compared them with other foods.

Dr. JOHN F. SINCLAIR of Philadelphia said that he thought the method of preparing the nuts for young children would be troublesome and that they had so many simple aids in the feeding of children that one scarcely felt like proposing another one that would require such patience in its preparation. It should also be remembered that children might have idiosyncrasies to nuts and fruits as they had to other foods.

Thursday, April 29—Third Day.

JOINT SESSION WITH SECTION ON SYPHILIS.

Hereditary Syphilis: The Early Manifestations, Starting from Intrauterine Life Up to One Year of Age.—Dr. LE GRAND KERR of Brooklyn presented this paper, in which he declared that congenital syphilis was not easy to diagnose. Scores of cases that he had seen in consultation had been variously diagnosed. The two conditions, comprising over 90 per cent. of the mistaken diagnoses, were malnutrition and bronchitis. Many had become accustomed to thinking of congenital syphilis only as it showed itself in a more or less virulent infection in the offspring. But there might be the hereditary transmission of the constitutional changes which were the result of the specific poison in the parent. The manifestation of these changes in the offspring were in more or less marked general disturbances which were not traceable to other sources. Those who considered only those cases in which a more or less virulent infection showed itself were taking a very narrow view of the subject. Infants were frequently seen exhibiting tissue changes which were attributable to syphilitic infection, but without any evidence of the usual syphilitic lesions. These manifestations might be called dystrophic, parasyphilitic, or toxinic, but they were the result of a syphilitic heredity. While there was abundant evidence that tuberculosis and alcohol produced dystrophies, those of syphilis were special in that they were varied and numerous. In syphilis acquired late in pregnancy the dystrophies were usually absent, since they were the result of the action of the specific poison upon forming organs and tissues. In making a diagnosis several facts should be considered: the family history, the appearance of the infant at birth, the type of the disease, and the appearance of symptoms some time after birth. In getting the history the question should never be asked "Have any of the family had syphilis?" But such a history of events should be obtained as would establish presumptive evidence as to the existence of the disease. These events were: (*a*) The tendency of the children of a given family to suffer from unaccountable anemias and malnutrition during the earlier periods of life, despite good hygienic and dietetic care. (*b*) The occurrence of anomalous types of disease in two or more children of the same family, or the unusual course of disease under similar circumstances. (*c*) Tardy development without a recognized cause, or with a recognized cause but out of all proportion to the cause, and occurring in two or more children of the same family. (*d*) The occurrence of a rachitic type of skull without other evidence of rachitis being proportionately marked. (*e*) History of the disease, direct or presumptive, in one or both parents. (*f*) A history of the abortive habit in the mother without definite cause. The rapid death of the fetus might be the only evidence of congenital syphilis, and these cases were commonly diagnosed as acute malnutrition. Probably many infants dying of "bronchitis" during the first weeks of life suffered in reality from syphilis of the lungs. Between birth and the appearance of active symptoms the Wassermann reaction as well as other tests was unreliable. Symptoms present at birth indicated severe infection, and such infants usually succumbed within a few days. After reviewing the symptoms that were seen at the time of birth, the author reviewed those which appeared some time after birth, most prominent of which were persistent rhinitis, fissures about the openings of the body, and the skin eruption which had been so variously described, due no doubt to the fact that it varied so greatly with the varying degree of severity of the infection. He referred to the nail involvement, thinning of the hair, enlargement of the spleen, hoarseness, and effects on the nervous system, and observed that enlargement of the testes was almost pathognomonic of congenital syphilis in early infancy. He called attention to epiphysitis as the most common accompaniment of early manifestation; and that with widespread bone involvement there might be crepitation which might be mistaken for paralysis. Changes in the skull, dactylitis, late eruption of the teeth, and hemorrhagic effusions, furnished further evidence of hereditary lues. It must be remembered that congenital syphilis was a much more fatal disease than the acquired form in adults, and as the vitality of the child was markedly affected by this infection one must be very guarded in his prognosis as to the future physical and mental vigor of the child.

Hereditary Syphilis: Later Manifestations after the Age of One Year.—Dr. L. E. LA FETRA of New York presented this communication. He stated that, although useful, the distinction between early and later hereditary syphilis was somewhat arbitrary and artificial. It had been customary to consider the manifestations of hereditary syphilis that appeared first about the time of the second dentition as those of late hereditary syphilis. In general these corresponded largely to those of the tertiary stage in adults, and the symptoms of congenital hereditary syphilis corresponded with those of secondary syphilis of the adult; but even in early infancy visceral and bone changes might occur, while on the other hand in the period following infancy there might be outbreaks of condylomata and of various secondary skin manifestations. The author reviewed the classical symptoms of late hereditary syphilis, calling attention to rhagades or their scars as being practically pathognomonic and describing the three types of Hutchinson's teeth. When present these tooth abnormalities were considered presumtive evidence of hereditary syphilis, but it must be borne in mind that they were often absent even when there were characteristic syphilitic changes in the bones in other parts of the body. A persistent hoarse voice might at times be the only symptom. The author said his experience had been limited to congenital abnormalities of the heart accompanying hereditary syphilis but he had never recognized syphilitic myocarditis in older children. Enlargement of the spleen and liver were common, while enlargement of the testes in early life fol-

lowed later by atrophy was almost diagnostic of syphilis, provided tuberculosis could be excluded. The extremities might show dactylitis closely resembling the spina ventosa of tuberculosis, but the differential diagnosis could be made by searching the rest of the body, or, if this showed nothing, by the Wassermann reaction. The most characteristic manifestations of late hereditary syphilis were the changes that took place in the long bones, and especially in the tibia. In addition to the enlargement and curvature of the tibia there was frequently marked irregularity of its surface, and occasionally larger or smaller nodules or indentations. The bone was apt to be tender on pressure or tapping. The extremities might show other changes, the most important of which was multiple arthritis which was a late manifestation and was commonly met with in the knees and ankles, usually, but not invariably, bilaterally. When the bones were not involved there might be a simple effusion of the synovial membrane with or without thickening, or there might be thickening of the synovial membrane, joint capsule, and adjacent tendon sheaths. The commonest form of this condition resembled arthritis deformans. After describing the skin lesions, the author stated that hypertrophy of the lymphoid tissue was general throughout the body, but most important for diagnostic purposes were the epitrochlear lymph nodes. If both of these were enlarged, and there had been no skin lesions on the hands and forearms, the finding was almost pathognomonic of syphilis, if tuberculous dactylitis or pyogenic infection were excluded. In view of the improvement that might reasonably be expected from proper treatment in nervous and mental conditions due to syphilis, the possibility of hereditary syphilis as their cause should be kept in mind and the Wassermann test done in all cases. In order to give some idea of the clinical types of hereditary syphilis met with in children, Dr. La Fetra said he had gone through the records of the Bellevue Hospital Children's Service for the past two and one-half years. Careful Wassermann tests had been made in all cases with suspicious physical signs or symptoms. During this period 148 cases of syphilis were admitted to the wards; of these three were cases of acquired syphilis, 85 were hereditary but under one year of age, and the remaining 60 were of the hereditary type and over one year of age. Of these 60 patients, 10 showed no symptoms or physical signs at all characteristic of hereditary syphilis. Many of these patients showed absolutely no abnormality, but it was known by the Wassermann reaction that they were suffering from a serious constitutional disease. In this connection it might be noted that because of the activity in prophylaxis of the Social Service Bureau children were sent to the hospital simply because they belonged to syphilitic families. Of these 60 cases there were suspicious or equivocal signs in 21, which, though suggestive, were not sufficiently characteristic to warrant the diagnosis of syphilis at the time of admission. Twenty-nine of the 60 showed signs that were characteristic of hereditary syphilis. The findings in these cases were tabulated and it was noted that the most common signs among the younger children were the eruption, rhagades, and condylomata; while among the older children the changes in the bones were most often met; next in frequency were feeble-mindedness, backward development, and affections of the central nervous system. There was no case of chorea or of juvenile tabes in this series. It was remarkable, in view of the stress laid by all teachers on Hutchinson's teeth in late hereditary syphilis, that among the 24 patients over six years of age this deformity was present only four times. Not once was Hutchinson's triad, of teeth defect, keratitis, and central deafness met with. This combination of signs, while undoubtedly pathognomonic, was seldom developed except in very severe and neglected cases. Enlargement of the epitrochlear lymph nodes was present in 18 out of the 60 cases. The lesson derived from this study was the well-worn one that early diagnosis with its corollary of vigorous treatment was of the highest value to the patient. As an aid to this early diagnosis in doubtful cases the Wassermann test carefully applied by a competent man might be relied upon almost absolutely.

Syphilis as a Cause of Feeble-Mindedness.—Dr. Henry H. Goddard of Vineland, N. J., presented this paper, in which he outlined the results of his efforts to ascertain to what extent syphilis was responsible for feeble-mindedness in the institution with which he was connected. He stated that this whole subject was in rather a chaotic condition since most of those who had endeavored to collect statistics had failed to make distinctions between the high grade morons and the low grade idiots. They had, perhaps, gone too far in assuming that if a parent had syphilis and the offspring was feeble-minded, therefore the syphilis was the cause of the feeble-mindedness. Dr. Goddard exhibited charts showing the results of his study of the family history of children of different grades of mental deficiency. While there were so many factors concerned that few definite conclusions were warranted, it seemed evident that syphilis was not nearly so frequent in the forebears of the feeble-minded as was feeble-mindedness itself or, at least, a neurotic family history. It was doubtful whether data was sufficiently reliable to warrant the statement that syphilis was much more prevalent among the feeble-minded than among the general population, but a greater prevalence among this class might be accounted for on the ground that this class of individuals were less able to protect themselves from the disease and less likely to seek treatment for it. In his series syphilis occurred more frequently among the high-grade morons than among the low-grade idiots. If syphilis was the cause of feeble-mindedness one would have expected to find it oftener among the low than the high-grade defectives. This entire field was one that invited further investigation.

X-Ray Diagnosis of Bone Lesions in Hereditary and Acquired Syphilis.—Dr. Wisner R. Townsend of New York gave this lantern slide demonstration. He stated that in the diagnosis of syphilitic bone disease the *x*-ray was a help but it must not be accepted by itself as conclusive evidence of syphilitic lesion. Taken in connection with other evidence points that were pathognomonic of syphilitic bone lesion were increase in the comparative thickness of the periosteum and thickening of the medullary cavity. Of course, there were borderline cases and one must not be led astray into thinking that syphilis could be diagnosed by the *x*-ray, but it was of great value in many instances and occasionally cleared up a doubtful diagnosis. Slides were shown illustrating the differences between syphilis and such conditions as osteochondritis sarcoma, hemorrhagic osteomyelitis, septic osteolyelitis, Paget's metaplastic ostemallacia, and infectious arthritides.

Dr. Sigmund Pollitzer of New York said that naturally the dermatologist and the syphilologist saw these cases from a somewhat different viewpoint from that of the pediatrist. The skin lesions of syphilis were as perfectly characteristic in infants as in adults. In addition to the symptoms that had been mentioned was a peculiar smooth condition of the palm of the hand. Onychia did not occur as frequently as paronychia. These lesions were of great importance and sufficiently characteristic to enable one to make a diagnosis. The speaker agreed with Dr. La Fetra in regar dto Hutchinson's teeth in syphilitic children; one saw Hutchinson's teeth in only a small proportion of cases. Again one must remember that all teeth defects were not Hutchinson's teeth. Of absolute importance was the Wasserman reaction. There were many cases of mental deficiency among syphilitics, but, of course, the mental defect might be due to something else. It must also be emphasized that when a lesion occurred in a syphilitic it was not necessarily due to the syphilis. This point was determined by the results of antisyphilitic treatment. The speaker said he made it a practice to examine the entire family of a syphilitic patient and had met with some rather surprising results. In closing emphasis was again laid on the point that a positive Wassermann always meant syphilis, but a negative reaction did not necessarily mean that syphilis was not present. This test should always be made when there was the slightest suspicion of syphilis.

Dr. John F. Sinclair of Philadelphia said the papers had been very illuminating and he was especially glad to hear Dr. Townsend say what he did, that the *x*-ray must not be too fully depended upon in making a diagnosis of syphilis. Dr. Sinclair related the history of a case in which the *x*-ray picture had been misleading and was glad to hear that one of Dr. Townsend's experience had found the same thing to be true. Dr. Goddard's paper was very interesting and he felt that its influence should be carried away. It was time to put the brakes on and not to be led too far astray by the statements that came to them in reference to the variety of manifestations that had been attributed to syphilis.

Dr. T. De Witt Sherman of Buffalo expressed the opinion that Dr. Goddard's statements in reference to the relation of feeblemindedness to syphilis were very

enlightening. He had met the question very fairly and squarely and had given them a line of thought that was very helpful.

Henry C. Baum of Syracuse called attention to one point which he said was characteristic of hereditary syphilis, and that was contracture of the biceps tendon and limitation of motion of the elbow joint. Fournier and Marshall had called attention to this symptom.

Dr. J. A. Ragone of Buffalo said that Finkelstein and his followers had called attention to a point of diagnostic value that had been overlooked, and that was that there might be bluish red spots on the soles of the feet; he had found them present quite consistently, but one had to get a little distance away from the foot to see them. Another sign was the peculiar shiny appearance of the outer portion of the soles of the feet; this glossy appearance was always diagnostic. Very few found the enlarged epitrochlear glands unless they searched very carefully, but by a careful search they could be found in very many cases.

Dr. William T. Shannahan of Sonyea said that in reference to the occurrence of syphilis in mental defectives and epileptics, he had employed the Wassermann reaction in 700 instances and it was positive in less than two per cent. of that number. In a German institution 800 tests gave about three per cent. positive. There seemed to be evidence showing that in these families there was some defective strain beside syphilis and alcohol.

Dr. John A. Fordyce of New York called attention to the resemblance of certain ulcerative conditions in syphilis and tuberculosis, and to the resemblance of lesions of Basedow's disease to those of gumma. The close resemblance of the lesions of tuberculosis and syphilis made it very difficult to distinguish between them at times.

Dr. Charles Bernstein of Rome said that some three years ago when they were not so accurate in making the Wassermann tests a recent graduate in medicine made 800 tests and found 38 per cent. of them positive. The following year 500 tests made by a more experienced worker gave only 4½ to 5 per cent. positive reactions; in these 4½ or 5 per cent. they found clinical manifestations of syphilis. Last year 300 examinations were made, and most of these belong to the 500 series, with the same results, so it appeared that in an institution with from fifteen to sixteen hundred inmates there were about 4½ or 5 per cent. that gave positive Wassermann reaction and showed clinical manifestations of the disease. More syphilitics were treated now and treated earlier than formerly, while at the same time the number of feebleminded was increasing, so it did not seem that syphilis was a very large factor in the causation of feeblemindedness, but it was often engrafted on feeblemindedness.

Dr. Herman G. Matzenger of Buffalo said that from Dr. Goddard's tables it seemed apparent that this class of feebleminded belonged to a defective type; they differed from the normal. Whether they were alcoholic, syphilitic, drug habitués, or what not, the fact was they were below par and mental defectiveness was the result. They knew a great deal about inheritance, but not much about heredity. The germ cell was the carrier of life and accidents through two or three generations and should not be spoken of as hereditary. There may be little warping for a time, but the tendency was toward the normal again. Again, nature found a way to protect herself by guarding the germ cell. The syphilitic was sterile, or the infants died, or the victim of syphilis was so unattractive as not to be sought in marriage. He could not say that syphilis had anything to do directly with feeblemindedness.

Dr. Joseph Roby of Rochester urged the necessity of checking up the inheritance in all cases of mental defectiveness or conditions where there was any suspicion of syphilis. He cited several cases in which the Wassermann test applied to the parents had given light on the diagnosis of the condition in the child, and in which, as a result, the proper treatment had led to great improvement both in mental and physical condition of the child.

(To be concluded.)

Reporting Contagious Diseases in Cincinnati.—The health department of Cincinnati has an arrangement with the post-office in that city whereby unstamped contagious-disease report cards mailed by physicians will be forwarded to the office of the department, the postage being paid out of a fund deposited for that purpose with the postmaster.

NEW YORK ACADEMY OF MEDICINE.

Special Meeting, Held April 20, 1915.

The President, Dr. Walter B. James, in the Chair.

This meeting was held for the purpose of urging that the Quarantine Station of the Port of New York, now in the hands of the New York State Government, be transferred to the United States Public Health Service. The present conditions in Europe make this step especially important at this time.

Dr. Walter B. James, in his introductory remarks, said that a distinguished contemporary philosopher of France had said that there was nothing so stable in a people as the fundamental groundwork of its thoughts, and this he supposed might help to explain the apathy of the general public towards preventive medicine. During all the many thousands of years when men had lived together a community life and until within comparatively recent times, preventive medicine did not exist. Disease, especially epidemic disease, was viewed as a scourge or punishment sent by some higher power. Resignation and patient submission were the only conditions that made life tolerable, so that these qualities came to be regarded as the highest virtue. With the discovery of the cause of disease all of the real mystery of it vanished and even today they had remedies, effective preventive remedies, for the multitude of maladies and especially of the communicable and epidemic diseases, so that now the same patient submission, the same resignation that for thousands of years were the highest virtue, had come to be crimes and it was perfectly fair to say today that for any community, and especially any public authorities in a community, to sit quietly under the scourge of an epidemic was a crime against humanity. Nevertheless, so stable was this fundamental groundwork of people's thoughts that they still found them apathetic, still harking back to resignation and submission, still applying the methods of two or five thousand years ago to the entirely changed conditions of today. Within a few days one branch of their State Legislature had passed a bill which indicated that they were in this state of mind. One of the wisest State health laws ever enacted created an admirable health board for the State of New York a little over a year ago. Within a few days a bill had been proposed which very materially curtailed the powers of the health council excepting in times of epidemic. Note the serious menace done in the proposition to check the public health activities until the epidemic had begun. Was not this a harking back to medieval times? The other proposed changes too would be distinctly steps backward. For more than a quarter of a century the New York Academy of Medicine had openly and publicly advocated the transfer of the Quarantine Station of the Port of New York to the national government. The reasons for this step, and they seemed to them to be more than adequate reasons, were given in the resolution, of which many of them had seen copies. The Academy of Medicine had maintained its position steadfastly and without change during all of these years. The Academy of Medicine desired to make it clearly understood that it had only words of praise for the manner in which the present health officer of the port had conducted his department. They made no criticism of the conscientiousness and efficiency of the present administration, nor indeed of that of the health officer who immediately preceded him, and the State had been lucky in the possession of these two public servants. In the past, however, they had seen administrations of this office which were not above criticism and where the political conditions that they were now desirous of seeing eliminated acted to seriously interfere with the operations of this important office. As long as the responsibility rested where it now rested they felt that there must be great uncertainty as to how the office would be administered under future administrations. Many other public bodies had joined the Academy of Medicine in this effort. Most of them were still with them, and many were represented tonight. One of the associations, however, which for over twenty years had stood shoulder to shoulder with them in their efforts to have the country's quarantine put on the best possible scientific basis, had seen fit to reverse its views of two decades ago, and that without the development of a single new fact, without the production of one single new argument. Its home was a temple tinged about with glistening marble columns, and when one entered its halls his eyes were dazed with the glare of all the polished stones of Holy Writ. This homely little build-

ing was insignificant compared to it, but here they did not change their views without some logical reason, some new facts, and they did not subordinate the health, the lives of the men, women, and children of the United States to the supposed, and as they believed, the wrongly supposed interests of the commerce of the city.

Last night an event took place which seemed to him to have a more far-reaching significance than had been generally appreciated, although he believed it was announced in today's papers. The Republican Club passed a resolution endorsing the position taken by the New York Academy of Medicine and recommended the quarantine transfer. Did not this suggest that the day was not far off when, in matters of public health at any rate, political consideration would be subordinated to the immediate public good? Here they had a prominent and important Republican organization recommending that a lucrative and important office with much patronage be taken out of the hands of a Republican State administration and be put into the hands of a Democratic national administration. Perhaps some day they would see commercial organizations taking the same broad view of the public good. There were two reasons for urging this change today. First, the fact that in their National Public Health Service they had what they believed to be, what they knew to be, the most capable and effective piece of machinery in the world for defending the people from communicable disease conveyed from other nations; and, second, because the melancholy state of affairs in Europe had for many months led the physicians to believe that with the advent of warm weather and especially with the coming to their shores of European immigrants, the danger of infectious disease would be greater than they had ever known them. At this meeting they had invited to speak only men who had a first-hand knowledge of their subject matter. One, Mr. Henry James, Jr., who would describe the existing conditions in Servia, had returned only a few days ago from an official tour of inspection of the Balkan States. Another, Dr. William C. Woodward of Washington, Health Officer of the District of Columbia, who would speak on quarantine, had occupied his present responsible position for over twenty years and was recognized as a practical authority on public health and preventive medicine. And finally, to present the constitutional aspects of the subject, they had invited ex-President Taft, than whom no man living had a broader view of this aspect of the subject, and who was particularly fitted to speak for the ability of the National Government to manage all the Quarantine Stations of the country, for it was under his administration that the Public Health Service reached its present high degree of efficiency and became what they believed to be the most perfect organization existing in the world today for the administration and enforcement of public health measures.

Dr. James said he had received letters approving of the effort to place the quarantine under the Public Health Service from 388 individuals, including physicians, surgeons and health officers throughout New York and other States, and representatives of many organizations. A few of these letters he read, among which was one from Surgeon General William C. Gorgas.

The resolutions which the Academy of Medicine had presented to the Legislature were as follows:

Whereas, of all the ports of this country New York ranks first as a receiving station for foreign goods and immigration, as well as a distributing center for the entire country; and,

Whereas, the Federal Government controls all the service incident to the administration of the Port of New York with the single exception of the quarantine, which is logically a part of the immigration service; and,

Whereas, the United States as a party to international quarantine agreements cannot guarantee their uniform observance unless all quarantine stations are under Federal control; and,

Whereas, all the ports of this country, with the exception of Baltimore and New York, for the reasons above cited have already ceded their quarantine functions wholly or in part to the Federal Government. Therefore be it

Resolved, that the economical and efficient administration of the quarantine service, and, above all, the safeguarding of the public health demand the transfer of the quarantine station of the port of New York from the State to the National Government; and be it further

Resolved, that the Government of the State of New York be and hereby is respectfully and earnestly urged to take immediate steps to secure such transfer.

The Present Health Conditions in Europe and Their Relations to This Country in the Coming Months.—Dr. HENRY JAMES, JR., described conditions as he had but recently seen them. He said that as the inevitable result of the war people were forced to live in a changed environment, and that these unusual conditions naturally favored epidemics. Conditions were much worse in Servia than elsewhere. Typhus, typhoid and relapsing fever were at present epidemic to an alarming extent in Servia; with the coming of warm weather cholera would probably appear. As yet these diseases had not invaded the armies in Austria, or the more northerly countries of Europe, but with the coming of warm weather there was every probability that they would do so. With the Austrian invasion of Servia more than 800,000 civilians were swept back into Servia and were forced to live in the most primitive conditions. The City of Nish had had its ordinary population increased from 25,000 to two or three times that number, and people were living and sleeping in railroad stations, restaurants, stables and other places under conditions which made it impossible to stop the spread of infection. If the Austrians should invade Servia they would carry back these infections with them. That these infections might appear at our doors was not a vague possibility but a real danger and one that we must be prepared to meet in the near future. When they left the plague ridden district of Servia it was with the feeling that everybody there was doomed.

The Menace of Inadequate Quarantine, and What an Efficient Quarantine Means to the Entire Country.—Mr. WILLIAM C. WOODWARD in presenting this phase of the subject, said that more than one quarter of a century ago, on April 27, 1859, there convened in the City of New York, at the old College of Physicians and Surgeons, the third annual National Quarantine and Sanitary Convention. After a careful survey of the situation this body put itself on record as being convinced that hope of bettering the conditions of that time lay only in the enactment of uniform State quarantine laws, and took action to bring about the enactment of such laws. Since that time quarantine has been made practically uniform in all the maritime commonwealths, new and old. There were four reasons why quarantine at the Port of New York should be made a part of the national quarantine system: First, because of its relation to the foreign affairs of the United States; second, because of its relations to the domestic affairs of the United States; third, because of its relation to the domestic affairs of the State of New York, and, fourth, because of the administrative affairs of the quarantine itself. The admission and exclusion of citizens of foreign countries and of merchandise were governed by the principles of international law, by the terms of treaties and by Federal statutes, and the enforcement of these laws lay essentially with the Federal Government and not with the State. A State might exclude from its territorial jurisdiction any person or thing that would jeopardize the health of its citizens, notwithstanding international law, treaty or statute, but just such efforts on the part of an individual State to substitute its judgment for the other States and for the United States were the things that strained our relations with foreign nations, and the harmonious relations between Federal and State officers. There was for the entire country one law for incoming immigrants, one law for customs, one law to insure the safety of navigation along our coasts, while for the exclusion of diseases, which of all things were no respecters of state lines, there might be possibly as many laws and as many establishments for their enforcement as there were commonwealths in the Union. That this was recognized in New York State was shown by the fact that in its administration of the Quarantine Station it relied for the efficiency of its service to a considerable extent upon information concerning foreign ports on the foreign service of the Federal Public Health Service for guidance in these matters, realizing that the cost of such a service would be prohibitive, and that legal obstacles would stand in the way. From the standpoint of domestic affairs, the quarantine port at New York should be under the Federal service, since a large number of persons and a large quantity of goods passing through this port are destined to other commonwealths. Other states could if they wished establish

their own inspection service against persons and things coming from abroad, even though their entry had been approved by the officers of the State of New York, but such a course would interfere with commerce in such a way as practically to prevent such a course. These other states relied upon the efficiency of the service maintained by the State of New York, but they had no voice in the control of its operation. Persistence in maintaining its own quarantine station, merely for the protection of the State of New York, rendered it inexpedient to establish a branch of the Federal service to which states in the interior were entitled. Were the question of a national quarantine to come before such states, there could be no doubt but that they would prefer to have this station in the hands of the Federal Government. Again, there was no reason why the State of New York should assume the responsibility of safeguarding the health of the United States and it appeared unfair to the State that it should have to make up deficiency in the cost of its quarantine service out of the general revenue of the State. From an administrative standpoint, the Federal Government was far better able to maintain an efficient quarantine service at the Port of New York than was the State itself. This was said without any reflection on the ability with which affairs of the New York service had been conducted. An efficient quarantine service demanded an organization sufficient to cope with emergencies. A sudden emergency might require an increase in the capacity of the establishment of 20, 50, possibly 100 per cent. within a few days or weeks, and this increase would have to be immediately efficient. The State could not reasonably provide such an elasticity of service, but the Federal service could readily adapt itself to such an emergency by assembling men and equipment from other parts of the country, where an ultimate increase could be made at a time when no serious need existed. The Federal Service would have an added advantage in the matter of appeals. The ranking officer of the port should have ample authority, but the ablest officers might at times want advice with respect to the passing of a vessel and its passengers, cargo, and crew in a doubtful case. It was easy to hold such a vessel, but modern quarantine sought to interfere as little as possible with the movements of persons and merchandise, and the efficient officer could in a case of doubt seek advice of his superior officer. Interested masters and owners of vessels and cargoes should have some appeal from decisions of the quarantine officer and in order to make such an appeal of value it should be directed to someone as far as possible removed from the influence of local prejudice and excitement, one whose position was not jeopardized by local politics, and one who had the training and experience that fitted him to act intelligently. Where other than in the Public Health Service could such men be found? Distance was no objection to the effective administration of the service, for California, Oregon, and Washington were efficiently administered from Washington, and if this could be done certainly the administration of the Port of New York would present no difficulties on that score. Of the many states that had discontinued their quarantine services and relied wholly upon the United States Government for protection, none had sought to reverse their policy in this respect. Bigness was no reason for refusing to make this transfer. It appeared that of the traffic passing through the Port of New York the larger percentage was destined to go beyond the limits of the city and of the State of New York than was the case in other ports, and if this was true then the country at large had a greater proportionate interest in the maintenance of quarantine at the Port of New York than it had at other ports. Finally, the fact should not be lost sight of in the event of a transfer of the quarantine to the Federal Government that the State still had the power through its sanitary officers to call a special conference of State and National Public Health officers to enable the State officers to bring pressure upon the Public Health Service to administer the quarantine at the Port of New York in a manner acceptable to the sanitary officers of this State. In closing Dr. Woodward declared that if there was anything that rendered such a transfer inexpedient he had failed to discover it.

Relation of the National Government to Quarantine and Other Public Health Agencies.—Hon. WILLIAM HOWARD TAFT, Ex-President of the United States, delivered this address, in which he stated that his service in the Philippines had brought him into close contact with the work of the Public Health Service under conditions calculated to show their ability to deal with many trying emergencies. While war was to be deplored one had to recognize that it had been productive of some good. The Spanish-American War had been productive of great good in that it brought the American profession of medicine into contact with tropical diseases through the Army, Navy and Marine Hospital services. From the time that the United States entered Cuba until the present, American medicine made more progress than it had in the preceding one hundred years. Mr. Taft spoke of the work of Walter Reid, Jesse Lazear and William C. Gorgas in ridding Cuba and Panama of yellow fever and malaria and of that of Victor C. Heiser, a Richard Strong in China and the Philippines. During his experience in the Philippines he had seen them deal effectively with smallpox, beriberi, cholera, amebic dysentery, bubonic plague and leprosy. He described somewhat in detail the conditions before and after vaccination against smallpox was made compulsory in the Philippines and said that it was hard to understand how any one could be opposed to vaccination in the face of evidence like that. He related that the late Professor Lounsbury of Yale once said to him that the most remarkable thing he knew of was the astounding capacity of the undergraduate mind to resist the acquisition of knowledge, and to those dealing with the problems of public health the capacity of the popular mind to resist the indubitable proof of facts must seem equally amazing. In addition to the splendid work done in Cuba, Panama, and the Philippines, it might be recalled that a few years ago, when there was an outbreak of yellow fever in Guayaquil, Dr. Terry, of the United States Public Health Service, was called in to clean up that city, and later a representative of the Service had shown most remarkable results in dealing with hookworm in Porto Rico. During the Spanish-American War there were 120,000 men in the Army and 20,000 cases of typhoid fever, with a mortality of 7 per cent. In the year 1912-13 an army of 18,000 men was sent to the Mexican border. These men had been treated with anti-typhoid vaccine and there was only one case of typhoid fever; that occurred in a man who had not been vaccinated. With all these facts in mind it was very evident that a Public Health Service that could do all these things could also manage the Port of New York. The Federal Government had in the Army, Navy and Public Health Service a corps of medical men who in point of ability to investigate disease, in point of ability and experience in preventing disease, and in point of numbers, was equal to any medical corps in the world. The National Government had every facility for dealing with disease. It had its agents in every dangerous port in the world to make reports on health conditions. The Federal Government now conducted fifty quarantine stations in this country, practically all excepting the one in New York. Mr. Taft declared the New York Health Department and Health Law was good, the best in the United States, and he had no intention of criticising it, and he hoped the bills that at present threatened its efficiency would be defeated. Yet, the quarantine was a national question since it had an intimate relation to foreign and interstate commerce. It naturally came under the province of the Federal Government, but was one field in which the State might act until Congress spoke. The contention that quarantine was a state matter and that Federal control was unconstitutional was as absurd as the claims of the anti-vaccination cranks. Under the present law, even if the State wished to continue to conduct the quarantine, the Federal Government could step in and assume control; it had the right to purchase the station. Such a transfer, say at $2,000,000, would probably not be unwelcome to the State Treasury, though he was not in a position to say whether the United States Treasury was in a position to pay. The objection had been raised that the Federal Public Health Service was not adequate to conduct the quarantine at the Port of New York. In reply to this it might be said that they were conducting stations in other large cities successfully, and mere size was no impediment to proper administration of such a service. Others again deprecated the rigid uniformity of the Federal regulations. There need be no fear on this score as variation was made in the regulations to meet local conditions. Some one else claimed that the Federal regulations did not include beriberi. The Federal regulations were such that they could be made

to include this disease as well as others. Again, it had been argued that the Federal Government could not interfere in the coastwise trade. This was wrong; the Federal Government could extend its authority to the coastwise trade just as to interstate commerce. Once more, there were some who feared that there would be a lack of personal responsibility on the part of Federal officers for particular localities. This, too, was a fallacy. There was, in fact, a greater sense of responsibility on the part of the men in the Federal Service, because politics were wholly eliminated; the places of the men in this service were not subject to change of administration. The Federal officers had no local interests at stake, were not influenced by local opinion, and had no object to attain by the concealment of actual conditions. In this connection Mr. Taft reviewed the history of the epidemic of bubonic plague in California, where the policy of concealment led to the calling in of the Federal Public Health Service with the result that they had been chasing ground squirrels ever since. There was no question but that the quarantine at the Port of New York could be conducted far more effectively and economically under the same head and government with the Customs and Immigration Bureaus. The administration of the quarantine at the Port of New York was a matter which directly concerned the entire country. It was true that New York was the largest port in the United States and that New York City was an important part of the United States, but it was not the whole country. This was where the New York Chamber of Commerce probably made its mistake. While most of the immigrants and a large amount of merchandise arrived here, they did not remain, but were distributed to the entire country. With the State administration of quarantine there was a division of authority that was not desirable. The Federal Government had made treaties with foreign nations involving questions of quarantine and should logically be in possession of the instruments by which those treaties were to be enforced. They had been told that with the close of the war they would be threatened with typhus fever and other infectious diseases. When they faced the world to meet these conditions it should be with a national and not a State system of quarantine. The transfer of the New York Quarantine Station might not be as simple a matter as had been supposed and hence there was all the more reason for agitation at the present time.

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

THE LIMITATION OF OFFSPRING. By WILLIAM J. ROBINSON, M.D. Published by The Critic and Guide Co., New York City. Price, $1.00; 245 pages.

TWO PAPERS ON PUBLIC SANITATION, AND THE SINGLE TAX. By Surgeon-General WILLIAM C. GORGAS, United States Army, and Professor LEWIS J. JOHNSON, Harvard University. Published by Joseph Fels Fund of America, Cincinnati, Ohio. Price, 3 cents; 23 pages.

DIE NICHTGONORRHOISCHE URETHRITIS BEIM MANNE. By Prof. Dr. C. ADRIAN. Published by Carl Marhold Verlagsbuchhandlung, in Halle, a. S. Preis, M. 1.80; 62 pages.

THE ASSOCIATED OUT-PATIENT CLINICS OF THE CITY OF NEW YORK. Second Annual Report, 1914.

PATHOLOGICAL TECHNIQUE. By MALLORY & WRIGHT. Published by W. B. Saunders Co. Sixth edition, revised and enlarged. Octavo of 536 pages with 174 illustrations. Philadelphia and London: W. Cloth; price, $3.00.

THE CLINICS OF JOHN B. MURPHY, M.D. At Mercy Hospital, Chicago. Published by W. B. Saunders Company. Volume LX; Number 11 (April, 1915). Octavo of 197 pages; 47 illustrations. Philadelphia and London. Published bi-monthly. Price, per year, paper, $8.00; cloth, $12.00.

TWENTY-FIRST ANNUAL REPORTS CRAIG COLONY FOR EPILEPTICS. Published by J. B. Lyon; 194 pages.

Therapeutic Hints.

Treatment of Sore and Fissured Nipples.—Bardet recommends the following ointment:

℞ Menthol,
Stovaine, āā 0.5 gram.
Zinc oxide, 5 grams.
Tincture of benzoin.
Vaseline, āā 10 grams.
Cocoa butter, 30 grams.
Essence of roses, 2 drops.
"Formulaire des Nouveaux Remèdes."

Treatment of the Dysphagia of Laryngeal Tuberculosis.—Lermoyez recommends insufflation of the larynx with the following:

℞ Morphine hydrochloride.
Milk sugar, āā 2 grams.
Powdered gum arabic, 2 grams.

Of this mixture 5 centigrams are to be insufflated each time.—*Paris Médical.*

Treatment of Tabetic Pains.—Mueller is said to recommend the following:

℞ Thiosinamine, 1 gram.
Glycerin, 1 gram.
Sodium salicylate, 2 grams.
Sterile distilled water, 10 cubic centimeters.

M. Sig.: One cubic centimeter to be injected intramuscularly daily or on alternate days.—*Riforma Medica.*

Treatment of Dysentery in the Army.—A. Robin describes a method of treatment which is said to be an old one and which has demonstrated its efficacy in the Balkan campaigns. There is administered the following:

℞ Pulverized kaolin, 94 parts.
Gum arabic, 5 parts.
Gum tragacanth, 1 part.

This is mixed with care after the gums have been pulverized and is kept in a firmly covered metal box. The dose is a tablespoonful mixed with a little water. As much as 200 grams of the powder may be taken in the course of the day.—*Bulletin Général de Thérapeutique.*

Alcoholic Stimulation in Typhoid Fever.—A. F. Plicque notes that alcohol is not as well borne in typhoid fever as in pneumonia, nevertheless it is useful in combating the adynamia and sustaining the heart. The following "wine-lemonade" may be given:

℞ Red wine, 250 grams.
Syrup of citric acid, 100 grams.
Distilled or boiled water, 750 grams.
Journal de Médecine et de Chirurgie.

Treatment of Gastric Vertigo.—Robin is accredited with the following formula:

℞ Calcined magnesia, 0.3 gram.
Prepared chalk.
Sodium bicarbonate, āā 0.2 gram.
Powdered nux vomica, 0.03 gram.
Powdered belladonna root, 0.02 gram.

M. ft. pulv. To be taken immediately after each meal.—*Riforma Medica.*

Local Applications of Neosalvarsan in Vincent's Angina.—Renaux points out that Zilz, Netter, and Aehard recommend the use locally of a ten per cent. solution of neosalvarsan in glycerin. This solution does not deteriorate for a long time; it is neither caustic nor painful; and it may be applied to the ulcers three times daily. The parts should previously be cleansed with physiological salt solution. —"Thèse de Paris."

FREUD FROM A SURGEON'S VIEWPOINT.*

By ROBERT T. MORRIS, M.D.,

NEW YORK.

PROFESSOR OF SURGERY AT THE NEW YORK POST GRADUATE MEDICAL SCHOOL AND HOSPITAL.

What is a dream? Stir a paddle about in the sea at night, and observe the flashes of light from so-called phosphorescent animal forms. That apparently represents the nature of a dream. The paddle for a dream is often a toxin, and the flashing particles are emanations from a group of brain cells that have been stirred into activity. In the flashing of sea animals we occasionally outline perfectly the form of a jellyfish. In a dream we occasionally see objects very distinctly.

The Mohammedan answers the question why we dream by saying that it is the will of God. That suffices. Higher up in the intellectual scale the Christian also says that we dream by the will of God, but in science we may take the question like all others directly back to the three physical entities for a beginning. Everything on earth we say is due to vibrations of energy, matter, and the ether. Matter in one form constitutes that group of brain cells belonging to the subjective mind. Let us imagine that these cells which are engaged with the subjective mind keep up a sort of constant harmonious humming while the objective mind vibrations strike a different chord. These brain cell movements when combined during the day are expressed in the music of thought. At night vibrations of the normal objective mind subside altogether, while those of the normal subjective mind continue in rhythmic motion like the heart muscle. Microbe toxin sets the cells which are devoted to the objective mind to vibrating in disbarmony whenever it causes partial awakening. The subjective mind responds, and disturbed memory then goes to humming, "remembering" in dreams many things that never occurred. It likewise anticipates in dreams many things that will never come to pass. During sleep the objective mind refuses to respond normally to the poisoned cell players, but cells of the subjective mind may respond in the form of dreams.

Dreams appear to result chiefly from toxic irritation of brain cells of the subliminal mind set, if we are to base our idea upon the frequency with which dreams are known to follow upon toxic impression. An unusual noise or a distended hollow viscus will also act like toxin by arousing partial brain action during sleep. Nightmare develops from toxic impression so distinctly that some individuals know just what particular food will cause nightmare.

Sleep is probably due to an automatic arrangement between the body cells. When the nerve cells expend their energy granules down to a certain point special hormones are then secreted, and messages are sent out from the chromaffin cells of the sympathetic ganglia, instructing all of the body cells to change their rate of vibration. Then we have sleep. A toxin or an unusual external impression breaking in during sleep plays upon these cells, and sets them to vibrating irregularly,—giving us dreams. Sleep is probably arranged for automatically very much as the water level in a boiler is regulated by automatic devices. When the neuricity granules of nerve cells get down to a certain level hormones are then poured out in messages which are sent to nerve cells of the whole body. Neuricity is so nearly allied to electricity that we may look upon sleep as a sort of automatic electric compensation process which is conducted by hormones.

The Freudian theory of the significance of dreams is not so cleverly drawn as are some of the Shakespeare-Baconian ciphers. Freud's theory is everywhere clouded by elusiveness and diffusiveness of statement. So far as most of us have been able to take testimony, there is no essential difference between day dreams and night dreams. We use the same materials from the conscious and subconscious mind in both cases, but night dreams are more of a jumble because we are pretty busy with sleep at that time and cannot lay our ideas out very straight. Dream wishes and wide awake wishes are also similar in character, and the tests which Freud applies for discovering hidden wishes in dreams if applied to normal waking consciousness would yield practically similar results. The working materials are about the same in both cases, variation being expressed in terms of quantity rather than in terms of kind. The dream has no special function, so far as Freud has given proof. The dream, some of us believe, is nothing more than a third rate psychic process, and would not occur at all excepting for abnormal stirring of brain cells. There is the closest sort of relationship between our dream consciousness and our wide awake consciousness. The complex of memories and thoughts, conscious and subconscious, in a most intricate weaving, appearing by day or by night as the case may be, gives opportunity for any one who is at all clever, to construct a cipher which will mislead all who do not walk with a testing stick. Freud, on the whole, is of great value when serving as a warning against the present day tendency to extreme specialization in study. He seems to have lost the sense of logical values, and plays the role of special pleader upon doubtful hypotheses. He minimizes or disregards unfavor-

*Advance pages from a book entitled "To-morrow's Topics," to be published by Doubleday Page & Company, New York.

able evidence instead of placing it in the structure, as would be done by men who make valid scientific advance. He builds monstrous and revolting structures upon a basis of shifting sand with the alertness of a paranoiac, using his obsession of sex as a rolling stone in the foundation.

Freud asserts that each person's memory, if allowed to wander freely, may usually be counted upon to furnish the information which the examiner wants. If that method fails the improved plan of Jung is employed. In the latter method the examiner makes use of word associations to remind a victim of what he should divulge. If the wandering mind and the prompting of Jung both fail, recourse is then had to a study of the dreams of the victim.

Proper analysis of the real meaning of dreams is said to require the services of an expert, and I quite agree to that proposition. We are told that the science of dreams is so rich in meaning that no dream carries its full or true significance on its face. Each sign has to be translated by a master in this new study, or else we common folks who have to drag along somehow would see nothing in it. When the Freuds are reminded that most dreams have no sexual features whatsoever, but present only a jumble of ordinary impressions, they reply that these are symbols. The various animals which are seen in dreams are said to be symbolic for the animal passions. Rapidly moving trains, or running waters typify hurrying emotions, they tell us. In dreams the lake and the bare landscape are simply elements of a picture language as well defined as the hieroglyphics of the Egyptians to the Freudian mind. We are seriously informed that apparent data have to be absolutely reversed at times in order to be rightly understood. My response to all this would be that the symbols are quite as well defined as are the features of plants which were used according to the doctrine of signatures. No more, no less! Making a parallel then to the doctrine of signatures the Freudian might say with his advanced idea—"A pinnate leaf may not look much like a liver but if one is broad minded enough he will clearly understand that it looks like a liver badly out of order, and had it not been for sex in parents there never would have been any leaf or liver." The old adherents of the doctrine of signatures stopped far short of this, and saw only the features of plants which symbolized parts of the body, or which suggested disease through some physical resemblance. The Freuds are more fanciful than the old adherents of the doctrine of signatures because they say it is not even necessary to have anything so plain as a plant signature in a dream. "Experts can find a symbol for the signature if the signature itself happens to be missing." A dream book that I once bought from an old darkey contained no more superstition than the dream theory of the Freuds, and it has the merit at least of stopping short of reversal of apparent data, for that indeed is the last straw.

Freud ascribes great value to dreams, and studies the "manifest dream content" and the "latent dream content" in order to find the meaning of a dream. A person who has no dreams is consequently left out of consideration. The form of a dream varies with the kind of toxin or kind of external impression. Thus a dream from indigestible sausage (colon bacilli?) would be different from that of indigestible beans (capsulated bacilli?),—would be different from one following too much use of alcohol,—would be different from the dreams caused through irritation of sympathetic ganglia by over-distended hollow viscera,—would be different from stirring of cells of the subjective mind by the first turn of the objective mind just before awakening. If my understanding of Freud's theory is correct, one would have to experience all of these five different kinds of dreams in order to bring out five different instances of repressed memory of five occasions of being sexually shocked in childhood.

When Towser, lying before the fireplace, whines in his sleep, growls, wags his tail, or awakens suddenly and looks about for the rabbit, perhaps, which he has seen in his sleep, I wonder what early sexual aggression has disturbed the poor dog. Is the rabbit symbolic of a shock received by the pup?

Freud constructs a metaphysical theory after the fashion that was characteristic of German method in the early half of the nineteenth century (Schilling-Hahnemann). He gives evidence of a morbid tendency to over-emphasize the potency of erotic influence in all of our experience, and the results of this preconception lead him into disgusting explanations. He insists that practically all dream wishes have origin in early sexual aggressions. What can be more morbid than his explanation of dreams which picture the death of beloved parents. He fails to use the dream as a proof that the dreamer wishes a parent dead at the present moment, but his theory concludes that the dreamer had wished a parent dead at some time in childhood. The antagonism of children to parents who punish them is made to explain some of these death dreams, but Freud wishes to account for the larger proportion of them on the basis of infantile erotic influences. "The man dreams of the death of his beloved father because in childhood he had felt sexual attraction toward his mother and has wished for the death of his father, who was his effectual rival." According to this idea the explanation can apply only to dreams in which the dead parent is of the same sex as the dreamer, and Freud forgets to explain how it is that dreams quite as frequently refer to parents of the opposite sex.

Freud and Breuer had a case of hysteria in which the patient fancied, or perhaps actually did detect a cause for self reproach. This had led, like other emotional disturbances, to the development of hysteria in that particular case. Confession led to the sort of recovery that might have occurred at a Roman Catholic confessional. Freud however tried to construct a system upon this case as a basis. He assumed that various obsessions, hysterical and others, had their origin in some sexual aggression of childhood. Obsessions, he says, are evolved from suppression of the memory of reproaches having sexual origin. In other words, memory of the sexual action being repulsive, is suppressed.

Let us say that Freud or Jung can take a given case of hysteria, or a given criminal, and by laborious and tedious analysis make an interesting association of concealed facts and hidden characteristics of the mind in these two particular individuals. Very well, how about the next case, and the one after that, and another one? Ah, there's the rub. The failures are not recorded by Freud and by Jung, because these failures are uninteresting to them. *Ergo*, their success is interesting as a sort of curiosity, in the cases in which it really occurs. Their successes cannot be reported as representing principles for support of a system unless general

application can be made, and unless failures are carefully recorded and reported. They must account for psychoses, hysteria particularly, in a class of patients who have never been aware of any sexual aggression, in fact, who consider any sexual experience as luck rather than as shock. Then there are the feeble-minded, who have various psychoses, and who probably have not been more impressed by early experience than by experiences of the moment. The psychoses in all these people have to be accounted for by Freud, or his system fails and belongs among the curiosities, like the fat man at the circus or the woman bearded.

Let us consider the case of Simple Sam, whom I have known during his entire life time in a certain village. He is feeble-minded, but manages to keep occupied at various jobs, excepting when some occasion like election or a fire leads to the development of hysteria. Sexual experiences of various sorts have dated from his childhood, but all of these he has looked upon as luck rather than as shock. Now if we are to leave out Towser and Simple Sam because they do not quite fit into the Freudian theory, where are we to stop leaving out instances in a system which must be like a wheel? A wheel cannot bear weight when even two spokes and the corresponding part of the felloe are missing. It is simply a plaything for the boys, looking very much like a wheel if the missing part is immersed deeply in mud (deep sexual idea). When such vital parts of a "system" are missing it has to be carried as "an abstract wheel in the head." Freud states that he found individual forms of hysteria to disappear whenever he aroused in the patient a memory of some sexual event which was causal in relation to development of symptoms, and when the patient gave verbal explanation for the emotion. He calls his treatment a catharsis of repressed emotions. He later retreated from his first position of belief in an aggression dating from childhood, and now places it at some time after puberty, but projected back into childhood. That indicates to my mind the instability of his basis, which is still more unstable if we consider the thousands of men and women with psychoses who have never suffered any feeling of shame from childhood to adult life either with or without cause for shame. Many of the feeble-minded have looked upon any sexual experience as a natural event rather than as aggression, and yet they present psychoses. What is to be done in order to bring unshocked cases under the Freudian theory? The method of treatment may remain to play a small role in providing means for treating a few people who happen to be proper subjects. These people are still subjects for pity, both before and after treatment. It leaves the larger number of patients with psychoses to be treated after the manner of the doctor whom it is said always gave a patient fits if he did not know what the right diagnosis was, because he knew how to cure fits. Freud thinks that motives of shame have resulted in repression of the consciousness of certain experiences, which then became subconscious. He traces the cause of repression inevitably into the field of sexuality, and makes this embrace not only shame, but also parental and filial affection, and all sex experiences and perversions. His contention is that the motive for repression having been discovered the patient can then reestablish a normal mental attitude toward the circumstance. Its train of symbols is supposed to disappear.

In psychanalysis both physician and patient assume an expectant attitude of mind. The doctor believes, and the patient is involuntarily led to believe, that a cure of the phobia will follow when a sexual "trauma or repression" has been revealed. The more revolting an incident which is unearthed the greater his power to cure. Freud requests the patient to allow herself to drift aimlessly in her communication with him, and to speak of everything that comes into her mind. She is not to suppress any thought or idea on the ground that an idea happens to be shameful or painful.

The very statement of this wish on the part of a physician would at once suggest to the mind of almost any woman the idea of concentrating attention upon some shameful or painful experience as meaning just what he was after. Among patients of hysterical temperament (and perhaps others) the desire to please or to surprise the doctor would certainly at times lead to the giving of misinformation, or in any event to disproportionate statement. Such statements when seized upon by the doctor would be dove-tailed into his preconceived notion, and he would then by suggestion lead the patient according to his personal hypnotic or suggestive ability.

The methods of Freud do not have the merit of "at least being harmless." We are beginning to hear of many cases of distressing mental perturbation on the part of patients who were subjected to unsuccessful attempts at extracting a confession about unfamiliar subjects. Suffering of an indignity is a phenomenon which is inseparable from the mental sex mauling of practically every individual who is subjected to Freudian search.

Nothing is said about shame and upheaval of the emotions as a final result of the treatment. How about that? The Freudian method may suggest sexual occurrences which never occurred at all. One of my patients said to me that what she had told the psychanalyst was not true at all, and she did not know why she told him such things. Freud suggests to his patients what he wants to get, and then gets it, therefore his method does not differ essentially from other suggestive methods. Just why a patient should be able to reestablish a normal mental attitude and to go forth rejoicing after a true confession or after a misstatement of fact suggested by the doctor, is to be explained on one ground only. It is to be explained on the ground of continued suggestion of the idea of rejoicing, and this idea will be good so long as it holds out. In this respect the Freudian system is not different from Christian Science. In the one case the system of suggestion is artificially constructed upon a hypothetical basis of sex. In the other cases—Christian Science—the method of suggestion is also artificially constructed and maintained, but upon a hypothetical basis of mind. According to the monistic unity doctrine Christian Science would give better results than the Freudian treatment, because mind is more deeply fundamental than sex. It includes consideration of First Cause, while sex is nothing more than a convenience belonging to some of the later plans of First Cause. Freud takes the mind no further back than to sex, whereas Christian Science takes it all the way back to First Cause. Freud then is more superficial than Christian Science. The more deeply fundamental the origin of function, the higher may we construct a building of logic, because of the deeper and stronger base. My observation of the practical re-

sults of Freudian treatment justifies the idea of this deeper base being the safer and stronger. Christian Science people are far happier than the Freudian products as a whole, as I have observed them. Both classes of patients however carry the manner and presence of people who are under the influence of suggestion from a source which lies outside of their own wills.

Before many years have passed we shall be developed to a point where people are taught to avoid acquiring one morbid condition in the hope of overcoming the effects of another morbid condition. At the present time Christian Science, Freud, alcohol, and caffeine are all alike in the sense that they relieve the stress of one morbid condition by introducing another morbid condition in its place, the latter being more agreeable. It is a matter of alternative only. Christian Science is milder in application, and agreeable to a greater number of people than is Freud. Caffeine is milder in its influence, and agreeable to a greater number of people than is alcohol; *ergo*, in the absence of a satisfactory hygienic alternative for morbid conditions I would prescribe for psychotic patients, tea and Christian Science, rather than alcohol and Freud. Under a proper system of eugenics which is to be developed, and is even now developing rapidly, we shall have fewer and fewer people with morbid conditions which require such alternatives for securing comfort.

All of this sick-head pother has been taken up seriously because of the natural attraction of men toward the sound of a brass band of deep thinking. Men in their egotism naturally like to keep step to this, without observing that the drum major himself is often walking backward. It may perhaps seem out of place for a surgeon to devote so much attention to the subject of Freud, but the latter represents, in the field of medicine, an influence which is directly opposed to the new scientific methods of today. The contrast makes him as large a figure as Satan in opposition to the Angel of Light. He represents the worst feature that we have had to combat in that progress in medicine which was first made by surgeons.

His system, like philosophy, represents educational conviction rather than scientific method. Upon observing the men who have become interested in Freud I note that he is much more attractive to those who have taken a course in arts at college than to those who took a course in science.

A system of this sort is attractive to those who are commonly known as learned men, and men who are proud of that distinction. The scientist knows better than to allow himself to be classified as a learned man if he can avoid it. There are too many things which the learned man knows that are not so. The scientist abhors being called "learned."

The psychanalysts believe that complex conditions of modern life make it more and more difficult for people to handle their fundamental instincts. If the nature and effect of fundamental instincts can be shown, people are then supposed to be enabled to manage these instincts more intelligently. A surgeon would assume, however, that a lame man having been shown why he was lame would walk no better than before, unless he continued to be supported by a crutch. When the psychanalyst lets go of the head of somebody who has become badly mixed up in the application of his instincts the surgeon believes that such an individual will soon be in trouble again. Another long and tedious pull at his head is then in prospect, unless the physiologist takes charge and obliges that individual to oxidize his toxins to a degree which allows his physiology to return to the point at which his instincts can go around and around as smoothly as the wheels of a watch. The confessional does not allow a man's head to go to destruction after the rendering of temporary aid; but the Freuds let it go when the patient's money gives out. At the confessional I presume no one ever attempts to mislead the priest, but one of my patients who had been treated by the method of psychanalysis said that she told the doctor a great many things that were not true because he seemed so eager to have her say what she did that it was not in her heart to disappoint him.

Psychanalysis claims to be the application of Darwinism to the psychic sphere (obverse of organic evolution); but Darwin collected facts and slowly came to conclusions, while Freud and Breuer began with a conclusion and then proceeded to add suitable facts for purposes of support, discarding unsuitable facts. This is the worst crime that is known to science, because it purloins the very essentials of art. It is the menace of a wolf in the covering of a sheep.

We shall hear much less of Freud a few years from now, although he has captivated the imagination of some of our psychiatrists at the present moment. His system has been constructed very much like the Marxian socialism by building a store house and then putting into it only such things as he wants.

The Freudian system is founded upon a basis of suggestion which affects both patient and practitioner unfavorably in the end. Incidentally in the course of development of the system much information of value has been gained—as exemplified in certain side studies by Brill. Information which was previously unknown is apt to be gained whenever we start to make new observation, even from a faulty basis. It was when trying to hybridize oaks with chestnuts that I accidentally made an observation which engaged the attention of biologists in all parts of the world. The fact that parthenogenesis occurred in trees of the organic rank of the Fagaceae was not anticipated, and might not have been discovered in the present century had I not been at work in a wrong way while attempting to collect facts bearing upon another question altogether. From osteopathy, which is based upon misconception and fraud, many facts of value have been incidentally collected. From Christian Science, based upon ideas of a paranoiac, much of substantial value has been applied in the way of treatment.

One of my inventions consisted in arranging a series of magnets in a box for the purpose of diverting magnetite from other forms of sand on the seashore. This apparatus pulled out a lot of iron, but the plant was not practical because the cost of power for moving and clearing the magnets was too great. In the same way, the Freudian system, osteopathy, Christian Science, or any fad, when swept over millions of people will pull out thousands who adhere to it for awhile. In the end such systems are not found to be quite worth their operating expenses, although something of good comes from all of them. The regular medical profession learned the use of lobelia from the Indians; from a shoemaker the operation for vesical calculus; from a postmaster the method for sounding Eusta-

chian tubes, from a monk how to use antimony. It draws to itself practical knowledge from all possible sources.

When the Freudian theory first began to attract my attention, in order to see how it would work out practically I referred clinical cases to different men who were making a study of the subject, but perceived at once that a poor man without means would have to be rather careful about going crazy. An attempt was made to obtain treatment by psychanalysis for one of my colleagues, a very dear friend, who had developed a psychosis. Doctors are supposed not to charge each other for services, and on this basis I could not find any Freudian who cared to take charge of my friend's case. Doctors, therefore, belong in that class of people who must think twice before developing a psychosis. There is one notable characteristic that runs pretty generally through all peculiar systems in medicine: they incidentally leave the poor out of account. Any system in medicine will fail, no matter how silly it may be, unless it takes charge of the poor. Freud does not do that, but furnishes the stimulus of a good business enterprise—I will not say by intention.

A psychiatrist who pins his faith to the Freud method of psychanalysis and psychotherapy might be charged with noting the commercial value of the method, because it seems to be carried out chiefly upon people who have sufficient means to pay for the valuable time of skilled physicians. I would not seriously ascribe any such sordid motive to interest in the subject, yet the incidental fact is a bit catchy —particularly when we consider this feature in relation to osteopathy and Christian Science.

Two post-impressionist psychiatrists, Freud and Jung, are at the present moment quarrelling over the question if the neurotic is "transfixed" to a certain period in his early infancy. Freud holds that the neurotic is dependent upon his infantile past, and the morbid psychic conflicts of later life develop through the powerful influence of that past. Restoration of health can occur only when the libido (Freud's vital energy—desire—any form of inherent force) becomes detached from the subconscious infantile fixation. Jung asks why there should be fixation of the libido to former infantile fantasies anyway. He thinks that the etiological element of the neurosis does not consist of the mere existence of infantile fantasies, but must be contained in the so-called fixation. He raises the question if the intensity of an Oedipus complex or of an Electra complex is really derived from fixation or from regression? When two men are thus engaged in struggle for possession of a single will-o'-the-wisp, let us hold our breaths and trust that the one who finally secures it will leave it to charity, for that is where the whole question rightfully belongs.

In selected cases the methods of Freud and Jung, like those of Du Bois, and the isolation-persuasion scheme of Déjerine, undoubtedly have a certain practical value, but all of these methods belong to the era of superstition. They serve a purpose, just as Calvinism serves a purpose, until such time as we may come into a full and free understanding of the chemical and physical nature of mental states. The Freudians, not content with analyzing real characters, try to extend their range of analysis to characters in imaginative literature. From the classics they construct such formulæ as the "Oedipus Complex" and the "Electra Complex." They try to show that the mental mechanisms of unconscious repression and of mental conflicts are the same for hysteria in actual patients as they are for fictitious creations, like the mental disease of Hamlet and Lady Macbeth. If anything more is needed for placing the views of the Freudians among metaphysical obsessions, they will no doubt furnish more. If Hamlet and Lady Macbeth, who did not exist, had unconscious repressions which also did not exist, the Freudians easily trace the history of these characters back to some sexual shock by a scientific method—which also does not exist, if we are still to place confidence in anything so old-fashioned as *reductio ad absurdum*.

Perhaps we may call the adherents of Freud the Froids, taking the name from "fraud," and the Greek "eidos." This is a mule word to be sure, wholly intolerable to word makers, but the mule is a very useful animal. The Froids are not frauds, because they really take themselves very seriously, but by adding the eidos we have a very good appellation. Supposing that the Froids were to tell us that the moon is made of green cheese. Green cheese at least is what one must have in mind when looking at the moon if he is broadminded enough. This use of the expression "broadmindedness" occurs frequently in their writings, and seems to be a sort of hidden appeal which they feel it necessary to make. They appeal also to the sympathies like the Christian Scientists, by asking—if there is much suffering from psychoses in the world, why not let a new method have a fair trial? They ask if they have not observed some new facts. Yes, one who looks at the moon and thinks it to be green cheese will note migratory birds passing. The mere fact that astronomers were looking toward the sky allowed them incidentally to make new notes relating to migration of the Limicolidæ.

The same powers which commonly allow a victim to recover from any one of various diseases after running the gantlet of drugs, allows him to recover after application of the Froid system. According to the Froids, nervous invalidism is largely a sign that the sufferers suffer because they cling unwittingly to modes of thought and feeling which belong to childhood stages of development. My assumption as a surgeon is more matter of fact, and I prefer to believe that modes of thought and feeling depend upon physical cell construction. Physical cell construction depends upon inherited tendencies, and upon response to normal or morbid products of metabolism. Metaphysical medicine, like the system of Freud, must be considered as a sort of art applied by mental experts.

All art must so vary with the personality of the artist, that we can never have any satisfactory artistic method in practice unless it is upon that basis of science which allows all men equally to apply it, when they have comprehended its data and its conclusions. Those who attempt healing upon a fanciful basis, like Freudism, would be classified as impostors were it not for the saving grace of the word "delusion." One may find characteristic articles by Froids in the *American Practitioner* for December, 1912, and in the *Transactions of the Harvey Society* for 1911. One is written by a teacher at Johns Hopkins and the other by a teacher at Harvard Medical School. The fact that teachers are allowed to write and speak upon this subject at two institutions of such high character is a good example of the value of freedom in teaching. The more important the man happens to be the more clearly his delusion is outlined.

The Freudians have made a few real discoveries,

but this is often done by men who do not half believe in any given quest. When men simply have their minds opened toward any cause and begin to look about they are pretty sure to find something surprising. This is illustrated by an experience which is related of two of my friends who were in such a hurry to leave the boathouse and get to fishing that one of them forgot to remove his necktie in which was a valuable diamond pin. After fishing all day with good success, it was suddenly discovered that the diamond pin was missing. It was believed to have been lost overboard during the excitement of landing some one of the fish. There was a question if some one of the fish in the vicinity seeing a bright object falling into the water had not swallowed it, and if that particular fish had been captured later. In a sort of half-hearted hope the two fishermen set about opening all of the bass and pickerel in the boat, and, when the very last bass was opened, there was the pin in a crack between two boards in the bottom of the boat under the bass. Suppose now, that while searching in the wrong way for the pin, the fishermen had incidentally run across a new cestoid entozoon which had not previously been known to belong to *Micropterus salmoides*. Furthermore, the fish had incidentally been prepared for the table, thus avoiding a discussion with the cook, and that is something worth while. Consequently, the result of their labors was not profitless. The result of labors of the Freudians will not be profitless, even though all of these metaphysicians wander far away from any such scientific procedure as hunting for and removing a real physical cause for symptoms. Metaphysics belongs to the era of superstition, while in medicine we have really progressed to the era of analysis, and are approaching the synthetic era. It is too late a day for medical subjects to be treated from the metaphysical standpoint. Surgery and bacteriology have done too much team work in getting the medical profession away from superstition, following the object teaching of Virchow, Liberator!

The Freudians would give metaphysical position (superstitious) to a psychosis like dementia praecox for instance, holding it to represent a conflict taking place in the mind; but the surgeon or bacteriologist would place the symptoms upon a purely physical basis. They might assume that microbe toxins were injuring the cells of certain ductless glands in such a way as to allow their internal secretion to escape directly into the circulation, and these, or the antibodies which they call out, were producing an impression which deprived cerebral lipoids of their oxygen carrying power—leading to the symptoms of dementia praecox.

Psychanalysts believe that in regression of function belonging to psychoses they find analogy to the retardations of development occurring in the structural part of organic life. Involution of the appendix vermiformis would be represented by some homologous psychic involution, according to the Freudian point of view. The surgeon, on the other hand, holds that psychoses depend upon structural retardations of development or maintenance. Curiously enough, certain phases of mental action which occur in connection with involution of the appendix really do seem to represent psychic involution (regression); but my own explanation would show a direct cause and effect relationship between the two conditions, rather than a coincidental or homologous relationship. Thus—in the course of involution of the appendix, fibroid replacement of lymph structure occurs. This fibroid tissue proceeds to contract like all hyperplastic connective tissue, incidentally pinching and irritating any nerve filaments which are entrapped. These irritated nerve filaments excite the sympathetic ganglia of the abdomen. Excited sympathetic ganglia fail to conduct proper secretion on the part of ductless glands, and we then have deranged hormone secretion. Deranged hormone secretion means impaired efficiency of the adjustment of function and of subsequent metabolism of toxins (microbic or proteolytic, or both). Toxins in the circulation have the effect of sensitizing protoplasm abnormally. Abnormally sensitized protoplasm is hampered when engaged in making the structures of physical brain cells. Structure of physical brain cells is so closely related to function of physical brain cells that our patient may now present symptoms of hysteria for instance, with features that the psychanalyst would classify as involutional psychic. The psychanalyst would not trace the evolutional psychic feature back to fibroid degeneration of the appendix, thus following a clearly marked physical clinical path step by step. He would metaphysically attempt a tracing of psychic features back to a primitive instinctive mechanism which had not become properly developed in that particular individual.

When carrying the subject into practical application, I have brought to an end very many psychic "regressions" by removing involuted appendices. Even the dreams were then stopped or changed in character. Every link in concatenation could be readily followed straight from the appendix to the psyche in these cases. The psychanalyst carrying the subject into practical application, might also have brought to an end the psychic regressions in some of these cases. He would have done it through the aid of suggestion, but most of his patients would not have remained permanently well, a tendency to relapse always remaining after treatment by suggestion. Patients would have reverted to their former morbid condition after awhile, for the reason that the fundamental cause for disturbance (the fibroid appendix) remained. If certain patients with psychic regression can be cured of that symptom through removal of their regressive appendices, how many of these Freudian patients may be better helped by physical methods than by metaphysical methods? The question of proportion in this matter is very important for the public, right now—daily—no time to be lost.

The psychanalyst believes that psycho-neuroses represent a moral conflict, in which contents of the patient's conscious mind are desperately struggling with contents of his unconscious mind. At least one surgeon believes that psycho-neuroses represent a physical conflict rather than a moral one. He believes that normal contents of the patient's physical brain cells are desperately struggling with abnormal contents of those very same physical brain cells—abnormal contents having made forcible entrance. Here, indeed, do we find a parting of the ways between psychanalyst and surgeon. We both relieve many of our patients so far as symptoms go. This is an everyday experience, and not a speculative proposition. One of us helps in one way, the other helps in another way. Which set of patients will best remain cured? This is a practical sort of question which will be asked by the general practitioner. He is the man who will want to know the best thing for his patients, and he is the judge who will settle the question. What has the common

sense doctor to say on the subject at the present moment?

If I understand Freud, he believes that psychoses have one common origin, and they may all be traced back to primitive normal sex instinct. If I understand Sidis, he also believes that the psychoses have one common origin and may all be traced back to primitive normal fear instinct. When two philosophers like Freud and Sidis start off on a race, but running in opposite directions, who wishes to lay a wager on the results of the race? Both men will get back to the original starting point eventually if they run far enough. (All the way around the world! Wouldn't that discourage you?) Having reached the starting point again, Freud and Sidis and the physiologist can all start off again side by side in a hare-and-hound race after the microbe. This time there will be fair probability of all three getting to a common goal quickly. The philosophers will use the largest number of words for cheering each other along, and the physiologist will use the largest number of instruments of precision for detecting tracks along the route. He will get to the goal first.

Philosophers start out with an obvious fact and push it along ahead of them, rolling it up with everything that will stick, until the mass becomes so large that the path is obscured. They keep right on rolling after the path is obscured and tumble off the brink into infinity.

According to Freud's school, psychic alienations mean repression of actual experiences, and the method of restoring comfort is similar to that of the Roman Catholic Church in its confessional. The Roman Catholic confessional antedates Freud's treatment. We have often found in medicine that empirical methods were useful in practice in advance of scientific explanation.

When first reading Freud I became very much engaged with his ideas, but when English translations appeared a different point of view developed. Reading the ideas from a surgeon's standpoint rather than from that of a psychiatrist, allowed me to escape being caught in the cogwheels of familiar terms which might hang to the traditions of a psychiatrist and drag him along into trouble.

Style often gives the measure for a lock step that leads one straight into the prison gate in literature. A man is likely to follow Swinburne where he might not wish to go, in lock step with captivating style. When I first took up Freud in the German his style was so scientific that I quite went with it, not realizing that it was a lock step and that *bona fide* science was running free in another direction altogether. When one has been trained to scientific reading it is somewhat difficult to escape from the dangers of a style like that of Freud, and I will excuse some of the psychiatrists who have followed him into a mental prison.

The style of many psychanalysts is quite hypnotic, and one is obliged to shake himself occasionally and say "Out!" when reading their literature. It is a style characteristic of a writer who has a misconception for which he is trying to prove premises by strenuous effort. When training was being given by my early teachers, if any fact seemed weak, we students were asked to put aside everything else—the entire theory if necessary—until positive or negative testimony could be obtained for bracing that fact.

Psychiatry as a whole must first go over to psychology and to bacteriology before it can be revamped and returned as a science. If it fails to stand the test, the psychologist and the bacteriologist will take away its foundations and use them for their own purposes. Psychology has already begun to do this by taking charge of the feeble-minded. Bacteriology has already begun to do it by showing the microbe influence upon certain abnormal forms of mental depression. It will be the fault of the psychiatrists if they allow their underpinnings to be stolen. It was the fault of the botanists to allow bacteriologists to run off with their biggest foundation stone, and hew it to their own liking. Tradition is a nice warm cap, but it comes down over the eyes unless we are on guard against that accident.

What is fanciful and unpractical on Monday is accepted by the critics on Tuesday and exceeded by the critics on Wednesday.

In psychic pathology we must always remember that function and structure are so closely related to each other that we cannot well study the one without a knowledge of the other. Until we know more of the natural or morbid brain action in relation to structural changes which are taking place in the physical brain cells under normal influences and under toxic influences, the time will not have arrived for a satisfactory basis for psychic therapy. The psychiatrists at present have to work arbitrarily from symptoms. This is particularly unfortunate, for it carries us back with a feeling of distress over the nomenclature and speculation of old psychology. It is regrettable because psychiatrists and psychologists are largely of the intellectual group among physicians, and in this group there is always a deadly tendency to do mental stunts in speculative philosophy. In the field of psychotherapy we may look for as much sonorous high class confusion during the next few years as we had in psychology twenty odd years ago—more confusion, in fact.

Scientific normal psychology at the present time has so little real relation to psychotherapy that we only add to the confusion by trying to adjust phenomena of morbid mental processes to fit our knowledge of normal processes. We must await the coming knowledge of changes in physical brain cell structure while protoplasm is being built up and broken down under both normal and morbid conditions, before a satisfactory basic ground can be found for psychanalysis or psychotherapy.

Under present conditions if we overhear two psychiatrists discussing the views of an absent third one, we shall hear something quite shocking. They will say contemptuously, "What does he know about psychanalysis or psychotherapy?" If we overhear the third one speaking with a fourth, and the first two are under discussion, the same comments will be made. Thanks for that much comfort at least!

While the older psychiatrists classified patients on the basis of symptoms, and the younger generation of psychiatrists are making involved construction with unknown factors, it seems to me safer to keep *un pied à terre* by holding that morbid structural arrangement of cell plasm of the physical brain leads to a corresponding expression of mental symptoms. Knowing already the nature of influence of many kinds of toxins upon many kinds of physical cells we may at least place psychoses on a sort of basis that is satisfactory to modern reasoning methods of the surgeon.

Psychiatrists group together symptoms belonging to psychoses of the human mind and then proceed

to build downward to classifications, very much as the religious philosophers assign a metaphysical place to God and then build downward with their creeds.

THE DIAGNOSIS AND TREATMENT OF CANCER OF THE STOMACH;

WITH A SUGGESTION AS TO POSSIBLE RACIAL TREATMENT OF CANCER.*

By JEROME MEYERS, M.D.,
ALBANY, N. Y.

THE positive diagnosis of cancer of the stomach is often difficult, not only in incipient cases, but also in advanced ones. Not infrequently the symptoms are vague and indeterminate, but preceding conditions are so similar to cancer that, after even the most conscientious physical examinations and chemical and microscopical analyses, great diagnostic reservation holds whether we are concerned with a benign condition, a beginning malignant process, or a developed carcinoma. And, moreover, to preface any discussion of gastric cancer diagnosis it must be said that the reliability and sureness of diagnosis depends largely on the skill, experience, and analytic judgment of the examiner, and that, unless the case be one of far advanced disease, the diagnosis can neither safely nor unquestionably be made on one symptom or on one day, but on related important findings that may demand many examinations of one sort or another, or direct inspection of the stomach through abdominal incision.

We may consider the symptoms and findings important in the diagnosis under three great heads: (1) Historical, (2) Gastric, (3) Paragastric.

1. The historical manifestations are such as we gain from the study of the life history of the patient, the comparative study of a long series of cases with carefully detailed history as given by Rudolf Schmidt (Bösartige Neubildungen) and from a knowledge of the pathology and growth of cancer. From such sources we may divide the histories of gastric cancer cases into three very important and significant groups.

(*a*) Those who have been perfectly well all their lives, have suffered little in the way of infectious diseases, and have never shown any prolonged or marked symptoms of digestive disorders. On the contrary they have always been in florid health and have been large eaters and drinkers. These at the dangerous or cancer age, 40-50-60, are suddenly attacked by what they term indigestion, which, however, against all treatment, has persisted or grown more severe. We may term this the sthenic or fulminating type of cancer of the stomach.

(*b*) Those who have been characterized by constitutional inferiority all their lives, have had many of the diseases of childhood, often showing signs of active or old quiescent tuberculosis, afflicted much with dyspeptic symptoms of the ptotic type. These constitute what we may call the congenital asthenic or gradual type.

(*c*) Those who over months or years have exhibited symptoms of gastric ulcer that at the cancer age adds to its ordinary symptoms loss of appetite, greater weakness, or diminishing gastric acidity. This we may name the ulcerous or secondary type.

*Read before the Albany County Medical Society, January 12, 1915.

The proper valuation of these preliminary symptoms is of highest importance in diagnosis, and particularly in the incipient cases, for there is little question that many of these cases showing these vague initial danger signals masquerade as indigestion, gastritis, catarrh, nervous indigestion, are quieted for the day by a scale of pepsin or a pinch of charcoal, when a proper recognition and interpretation might lead to early diagnosis and possible salvation of the patient. The public should be told again and again of the early suspicious signs of the malady, warned against self-medication across the drug counter with patent medicines that hide symptoms, but bring again and again the ignorant or unheeding sufferer to his grave, and impressed that unless early diagnosis is attained, the mortality is 100 per cent.

2. The gastric manifestations are those which result from the growth of the cancer in the walls of the stomach, causing more or less striking subjective and objective signs, according to the location and type of the neoplasm.

Of importance is, first, the disturbance in motor or mechanical function. Early cancer of the pylorus may cause little subjective disturbance in the exit of food, there being no gross vomiting, but merely eructations of gas or sour fluid with perhaps an odor of hydrogen sulphide, or a sensation of rumbling about the pylorus. It should be borne in mind that growths in the cardia may at times give symptoms of apparent obstruction of the pylorus. If the growth is distant from the pylorus, and does not seriously compromise the lumen of the stomach, or if the growth involve the walls without constricting the ostia, we may have no vomiting in the early stages, or in even the late scenes of carcinoma; so vomiting is not necessary for the diagnosis. This is to be emphasized, for it is a deep belief among the people that without vomiting there can be no cancer of the stomach, a belief which undoubtedly delays medical attendance, and which tends to cast question at the physician's diagnosis, and so hinder and defer surgical intervention. If the pylorus is markedly blocked there follows dilatation with more or less periodic vomiting, ballooning of the stomach, and visible waves of peristalsis or even antiperistalsis.

Naturally a growth at the cardia encroaching on the esophagus will lead to vomiting soon after eating or periodic vomiting of undigested food with alkaline mucoid fluid or bile stained material. One should never fail to ask a patient if there is any disturbance in swallowing, for he often fails to tell of dysphagia, so that growths, especially early ones, at or near the cardia, are overlooked. The time of the swallowing sounds should always be noted in any suspicious case.

Pain accompanying the growth and obstruction is a variable quantity which in some cases, especially about the pylorus, may be moderately marked early in the disease, particularly if there be spasm and hyperperistalsis, but it can disappear when the stomach begins to dilate. Pain is often absent, or becomes severe only in the later stages—a matter of great diagnostic importance, for just as pain is unnecessary for the diagnosis of uterine or mammary cancer, so pain is not a postulate in the diagnosis of gastric cancer. Just as soon as the popular fallacy that pain must always accompany cancer is dispelled, so soon will earlier diagnosis of cancer of the stomach be possible.

The tumor may be palpable, it may not be; in the early stages it very probably will not be, and when it is situated on the posterior surface of the stomach, when adherent to or beneath inferior surface of the liver, when high toward the cardia under the left ribs, it may deny itself to the sense of touch. It should be borne in mind that the whole stomach wall may be involved so that we palpate a firm organ or, in cirrhotic forms of growth a greatly shrunken viscus. Examination of the patient on the back, on the abdomen, in the right and left positions, and standing may yield a tumor that through diminutive size or deep position is otherwise secreted. One should always know just where the stomach is located and realize that even if he feel a tumor below the umbilicus it may be part of a ptotic stomach, in which case the tumor may be very movable. Of large diagnostic value is the evidence of muscular rigidity or slight tenderness to palpation in place of a tumor, especially in growths of the posterior wall. At times a systolic murmur, not due to the aorta, may be heard over a tumor or a site of suspicion.

Besides the motor disturbances, secretory ones are of importance in diagnosis. The absence or diminution of hydrochloric acid, taken with other symptoms, speaks for cancer, but should never alone constitute ground for the assumption of cancer; and, what is of more importance, the finding of a lack of hydrochloric acid in the cancer age should instantly arouse the suspicion of cancer, and should make us obstinately adhere to cancer until by proper examination we decide otherwise. A patient at the dangerous age with any anomaly of gastric digestion should be held guilty of cancer until proved innocent. The degree of HCl must vary with the age of the cancer and must differ with the type of onset, whether it is sthenic, asthenic, or ulcerous, so that the presence, or absence or diminution of HCl is in itself no proof of existence or absence of cancer. Many individuals have relative or absolute loss of hydrochloric acid as in achylia gastrica, pernicious anemia, and gall-bladder disturbances, often with no gastric discomfort over long periods. The diminution of HCl with lactic acid bacilli denotes gross obstruction, usually pyloric, and means almost always more or less advanced cancer. But the amount of hydrochloric acid may be normal or increased, there may be stasis with sarcinæ, and still cancer be present. But neither lactic acid bacilli, nor lactic acid, nor sarcinæ are necessary for the diagnosis. They may never be present, if the growth does not compromise the lumen of the stomach, so that the bald statement that lactic acid and lactic acid bacilli are found in cancer of the stomach is not true, and may be very misleading. Furthermore, they have no diagnostic value if found only in small numbers or quantity. The degree of acidity or the presence of extraneous acids is then not conclusive of cancer in the examination of the test breakfast, particularly in early cases without palpable tumor.

The most important finding in the stomach contents is blood. All malignant neoplasms tend to necrose and bleed, some more, some less, and herein often lies the key to the ultimate door of positive diagnosis. Without the presence of blood at some time, in either the stomach or the stool, the diagnosis of gastric cancer is impossible. Its presence together with suspicious onset at the cancer age, or with a tumor, or with diminished HCl, or found constantly in the stool with mere weakness in the old is highly suspicious, and if we can exclude old ulcer with tumor formation, syphilis of the stomach which may simulate all forms of cancer, gastritis anacida hemorrhagica due to gall-bladder or appendical disease, or cirrhosis hepatis, or other local or general disease, the diagnosis of cancer is very sure. The presence of tryptophan in the stomach contents may occur at times in positive cases, but in my experience has not been very reliable. Flagellates and amebæ may be seen, especially in carcinoma of the fundus, and while not pathognomonic, are important findings.

An *x*-ray examination of the stomach may clinch a diagnosis, but cannot establish a case of cancer by itself. It is valuable especially if the tumor be situated near the antrum or the pylorus. Fluoroscopic examination renders good service in some cases by showing interference with peristalsis and possibly antiperistalsis, denoting infiltration of the gastric wall. The *x*-ray is also of use when we cannot otherwise determine the exact position of the stomach, or if it is not advisable to pass a stomach tube. It cannot be relied upon to diagnosticate carcinoma; it may yield anatomical findings which must be interpreted in the light of other symptoms and tests.

3. The paragastric manifestations constitute those found secondary to the local growth; in other organs, in the lymphatic system, and in the blood. These symptoms are usually late ones, and often of value only in the school of differential diagnosis. Enlargement of the liver from metastases should always be sought. Secondary growth in the pouch of Douglas, felt for by rectal examination, may be one of the earliest implantations. Superficial involvement about the umbilicus may be early. Pleurisy or atelectasis at the base of the left lung may be found with high left-sided growths. Enlargement of the left supraclavicular glands points to retroperitoneal involvement. A moderate daily rise in temperature may occur, especially in the medullary forms that tend to ulcerate, so that unexplained fever at the cancer age should be held suspicious. The emaciation, cachexia, and weakness are of no great deciding value, as they occur late, and may be surprisingly absent at times. There may be edema, particularly about the ankles, but the red blood cells are not always markedly reduced, and may in obstructive cases run quite high. Constipation may be an early symptom and an important one, and should be fully considered. The blood serum may contain antibodies or antiferments through which confirmative evidence of carcinoma may be gained. Such substances are the basis of the antitryptic index test of Brieger and the Abderhalden test for carcinoma. The writer has had personal experience with the former only, and in the few cases in which he has applied it, has found it to tally with the clinical symptoms and findings.

From the foregoing we may deduce these conclusions regarding the diagnosis of gastric cancer:

(1) Never diagnose cancer on a single symptom.

(2) Suspect cancer in everyone who complains of gastric disturbance and prove otherwise.

(3) Do not exclude cancer because of absence of tumor.

(4) Do not exclude cancer because of absence of vomiting.

(5) Do not exclude cancer because of absence of pain.

(6) Do not exclude cancer because of absence of anorexia.

(7) Do not exclude cancer because of absence of lactic acid bacilli or lactic acid.

(8) Do not exclude cancer because of early age.

(9) Do not exclude cancer because of normal or increased HCl.

(10) Remember that blood in the stomach or stool is the most important symptom in the diagnosis of gastric cancer.

(11) Hold suspect of cancer all cases that continue to show blood in the stomach or stool after proper treatment.

(12) Hold suspect all those who show gastric disorders at the cancer age whether of sudden onset, old standing, or preceded by ulcer symptoms.

(13) Hold suspect those who fail to get relief from proper treatment.

(14) Consider syphilis in all cases of tumor. The tumor may be gumma. It is well to do a Wassermann reaction in all cases whether surely cancer or not.

The treatment of cancer of the stomach in those who can not or will not undergo some surgical procedure is largely terminal therapeutics. If neither of the openings is affected, there may be little to do, the patient may be able to take liquid, semi-solid, and even solid food, and may even gain in weight. If there is obstruction at the cardia, the case is far more difficult, due to the difficulty of food entering the stomach, with consequent dilatation of the esophagus with irritation and vomiting. A very careful liquid diet of high caloric value is indicated, one that shall not irritate but soothe by its demulcent action. The best articles are thin cereal decoctions or gruels, milk, milk and flour soups, raw eggs, cream, and olive oil. These may pass the obstruction, have a high food value, and tend to overcome any muscular spasm that may be abetting the organic stricture. Cleaning out the esophagus with the stomach pump and leaving in 2 or 3 oz. of olive oil may be of more value than the passing of sounds which are apt to injure the tissues and increase spasm. I have recently, in a case of esophageal dilatation in which the patient could not take the ordinary stomach tube, used the duodenal pump. It caused the patient very little discomfort and acted much like a siphon tube. Sips of diluted hydrogen peroxide may be swallowed in the hope that it will enlarge the passage by dissolving the necrotic tissue of the growth, thus giving a clearer and larger passage. Atropine may be given subcutaneously to allay spasm. With the growth at the pylorus, the indication is to prevent the large accumulation in the stomach of food, saliva and gastric secretions with the subsequent distress and vomiting. To this end food in small quantities and of small size must be prescribed; milk, cream, raw egg, milk, cream and flour soups, malted preparations, beef-juice, thin cereals and gruels, possibly finely chopped meats, hash. Besides gastric lavage at varying intervals depending on the degree of stasis and the severity of the symptoms may be necessary. In all these cases HCl, condurango, nux vomica, pepsin, pancreatin, and like substances may be employed to aid digestion. Gastrointestinal antiseptics, such as resorcinol or menthol, may be used to depress bacterial action. And in all cases the last resort, morphine, may become imperative to alleviate pain and procure rest and sleep for the afflicted patient.

Of biological treatment of cancer there are two methods, passive immunization by the injection of antisera, and active immunization by vaccines composed of cancer tissue or embryonal tissues. The latter method has proved the more hopeful, but even here the comparatively few apparent successes have been questioned. Such treatment might be instituted in gastric cancer, but should not defer operation, if there is hope of cure by excision.

There is a wider field of treatment than that of the individual, and that is of the race. Cancer is a peculiar affection of the human family in that in the preponderance of cases it attacks at an age when child-producing and child-bearing are not frequent. Other diseases occur in the earlier life of man and woman, so that if there are any antibodies or special resistance passed from the parents to the children, the offspring may benefit in the way of immunity to disease, and thus the race is guarded. This is not so in cancer, for even if the host of cancer does elaborate any antibodies against his or her disease, yet through age or shortened life he or she does not transmit to any descendants. And it may be for this reason that cancer is on the increase because we have more people in the world to-day only a few of whom can possibly be the sons or daughters of cancer fathers or mothers. If the cancer patients could produce or bear children there might come a time, perhaps very distant, when the human being would develop more resistance against cancer than he now possesses. As it is now, cancer cases serve no general purpose of immunization. If this view seems vague and to have little bearing on treatment, it should be remembered that with all our research and knowledge of cancer we have nothing like a specific treatment for internal cancer, and that in the application of such a biological eugenic principle may be some future ray of hope.

In the face of a situation so serious and baffling it would seem advisable to urge men and women with cancer to produce children before they die. If they be not married it would be well for the State to sanction and provide for marriage so that all cancer material could be employed to produce children who might be immune through transmitted resistance. If time should show that there was a possibility of such immunization in the human race, it would not be many centuries before most of the earth's population might be direct descendants of cancer patients.

REPORT OF A CASE OF CONJUGAL SYPHILIS, WITH CONCLUSIONS.*

By EDWARD LIVINGSTON HUNT, M. D.,

NEW YORK.

NEUROLOGIST TO ST. LUKE'S, THE CITY HOSPITAL, LINCOLN HOSPITAL, NEW YORK CITY HOME FOR THE AGED, THE WORKHOUSE AND PENITENTIARY.

Conjugal syphilis is of common occurrence. The literature of France and Belgium is especially prolific on the subject, as is evidenced by the reports of Fournier, Stillman, and Raulin. The experience of most observers points to the fact that in conjugal syphilis the tendency is preeminently toward involvement of the nervous system. Many cases have been recorded of marital tabes and marital paresis, and marital cerebrospinal syphilis. This may, of course, arise from concealment, faulty diagnosis, or ineffectual treatment.

In passing, it may be of interest to note, that Fournier, in regard to the infection of women,

*Read before the Alumni Association of the City Hospital, on February 17, 1915.

always reached the same conclusion, namely that out of every hundred syphilitic women who had been infected sexually, eighty were immoral and twenty were married to men whom he found to be syphilitic, and again that twenty years ago cases of conjugal syphilis, in which one of the parties developed general paresis, were cited to call attention to the close connection that was then thought to exist between general paresis and syphilis.

The case which I am about to tell you of occurred in two old people, who had been married for thirty years. They had raised a large family, and had prospered. It was not until toward their sixtieth year that any symptoms of ill health developed. It was the wife who first displayed symptoms, although I am now satisfied, from a careful study of the situation, that the husband was the offender. These two old people, once they had become ill, began to lose very rapidly. This was especially true as regards their mental deterioration. The husband became confused, irritable, unreasonable, and at times violent; the wife depressed, suspicious, and surly. He showed no physical signs, she very marked ones. The case, as it was presented to me, was as follows:

In 1910, Mrs. A., sixty-three years old, complained of stiffness in the legs, unsteadiness on her feet, difficulty in walking, and great mental depression. She had no interest in anything, refused to go anywhere, feared that she was ruined, disliked meeting people, and became irritable, unmanageable, and surly.

The physical examination showed unequal pupils, Romberg, a slightly ataxic gait, and absent knee-jerks. No cardia. There was no history of either alcohol or syphilis, and no suspicion of either. Her husband was perfectly well. The Wassermann test was negative. She was seen by several consultants here, who agreed that the diagnosis was probably a combined system disease, the cause of which was unknown. It did not seem advisable to give any mercury, at that time salvarsan was not generally used, and the symptoms which seemed to call most for treatment were the mental ones. Accordingly, the patient was placed in a sanatorium, with a good nurse, and given tonic treatment, irrigation, and baths. She improved very considerably in both physical and mental symptoms, so that it was generally conceded that the course of events had confirmed the diagnosis.

Three years later, in 1913, her husband, to whom she had been married for thirty years, had a slight stroke, followed by considerable and progressive mental impairment. From having been a very active and remarkable business man, he became childish, egotistic, self-centered, irritable, and somewhat demented. He could walk with difficulty, lost control of his sphincters and then displayed mental symptoms suggestive of Korsakoff's psychosis. He became disoriented, confused, and fabricated. There was no history of either alcohol or syphilis. The physical examination was absolutely negative. The Wassermann test on him proved negative. The urine showed from two to five degrees of sugar. The diagnosis appeared to be diabetes, plus arteriosclerosis. It was decided to try the luetin test. This gave at the end of seven days a positive reaction, that is, there appeared over the infected area two small red papules. The diagnosis was then made, one of syphilitic dementia. A lumbar puncture revealed a positive Wassermann, a positive globulin, and twenty-two cells. This patient was at once given hypodermics of the salicylate of mercury and intravenous doses of neosalvarsan, 0.4, 0.5 to 0.6 gram each. The improvement began almost immediately and continued slowly but steadily for over a year. He regained control of the sphincters, was able to walk, the sugar in the urine disappeared and the mental condition returned to almost normal. Another Wassermann on the blood was made after the initial dose of neosalvarsan. This one was positive.

In June, 1913 Mrs. A., was then sent for, and another Wassermann was made on her. This proved to be indeterminate. A lumbar puncture was made: there were twenty-one cells. The reaction was positive to the Wassermann and to the butyric acid tests.

It was then decided to place her on antispecific treatment. She was given hypodermics of the salicylate of mercury every week for four months, beginning with one-half a grain, and increasing up to one grain. To this were added a good nurse, country life, and tonic treatment. She improved very steadily, the depression lifted, the peculiar form of mental aberration abated, the walking grew better, and she became stronger. At the end of four months, not sooner, she was given four doses of neosalvarsan intravenously. The first dose was 0.45 gram, the remaining three 0.6. These doses were administered two weeks apart.

She was then allowed to go home, and all treatment was suspended. At the end of two months, that is, in February, 1914, another lumbar puncture was made. This time the cell count was eight, the butyric acid test for globulin was negative, and the Wassermann test was indeterminate. The treatment of both mercury and neosalvarsan was then continued for another four months, with continued improvement.

As we can now look back on these cases with these complete records over a period of four years, it is possible to make a definite and comprehensive diagnosis. The husband was, of course, infected several years previous. He, in turn, infected his wife. The form which the poison assumed in him was that of a specific endarteritis, terminating in a syphilitic dementia. Added to this there was a syphilitic pancreatitis. The case of the wife was one of taboparesis.

These two people are now about 50 per cent. better than they were. The treatment has been pushed very steadily; it has consisted of hypodermics of the salicylate of mercury, from $\frac{3}{4}$ to $1\frac{1}{2}$ grains, given weekly for three weeks, and then intravenous doses of 0.5 gram of neosalvarsan. Every three months the antispecific treatment has been stopped for a few weeks, and the patient has been given tonics. These cases are reported for various reasons. They teach the following facts:

(1) The importance of the *cerebrospinal fluid examination* as a routine measure in every neurological case. Had it been made at once in the case of the husband and wife, it would have made clear the diagnosis.

(2) The value of luetin. It was the luetin test which first made certain the diagnosis of syphilis.

(3) The importance and aid of a provocative dose of salvarsan. It was following the first dose of salvarsan that the blood Wassermann became positive in the case of the husband.

(4) The various forms in which the syphilitic poison may attack the system.

(5) The uncertainty of the Wassermann test when applied only to the blood.

(6) The value of combined treatment of mercury and salvarsan.

(7) The value of the intravenous form of administration of salvarsan.

(8) The very advanced age at which both of these patients were affected.

(9) The fact that reliance should not be placed upon the report of a single laboratory. No doubt in one of these two cases, if not in both, had two or three laboratories made the Wassermann test, a positive reaction would have been returned.

(10) The fact that all sugar in the urine is not of diabetic origin.

(11) The fact that the original source of infection became affected later than the second person.

(12) The absence of an aortitis in either case.

(13) The marked improvement which appeared in each of these cases, in spite of their advanced age.

THE ALOPECIAS.*

By LOUIS B. MOUNT, M.D.,

ALBANY, N. Y.

THE term alopecia was well known to the ancients, for Celsus made use of the word to denote any form of baldness, no matter what the cause might be. He probably coined the word from the Greek ἀλώπηξ, which means a fox, because foxes often have bald spots on their coats.

The great advances made in both clinical and microscopic study, notably in the last century, have made possible the differentiation of the following types of alopecia: (1) Alopecia congenita; (2) Alopecia prematura, Alopecia senilis; (3) Alopecia seborrhoeica; (4) Alopecia areata; (5) Alopecia mycotica; (6) Alopecia symptomatica.

Alopecia congenita needs but little description. As the term implies, it is an arrested or faulty development of the hair-producing apparatus. The child is born with remnants of fetal hair which soon drops out, or he is born without any covering at all for his scalp. This condition may be permanent, or after several months or years there may be a growth of hair, at first light in color, almost pigment free, and very fine, but as time goes on it becomes stronger, more numerous and pigmented.

As alopecia congenita is looked upon as an anomaly of formation, alopecia senilis might almost be called a physiological process because it occurs to a greater or lesser extent in nearly all old people. This form of baldness is remarkable because of its symmetry, whether occurring on the vertex so as to produce a tonsure like that of a priest, or whether limited to the frontal region, or so extensive as to involve nearly the entire calvarium, leaving a fringe of hairs at the occiput and temples. The distinctive feature is the entire absence of any pathological process clinically. It is possible that the reason for its being so much more common in men than in women may be ascribed to the difference in the head dress worn by the two sexes. The time of its occurrence depends upon the individual, his inherited tendencies, and the life he has led.

When this same picture occurs in those who have not attained advanced years, it is called alopecia prematura, and the old German saying, "Die Glatzenbesitzer haben sich die Haare wegamuesiert," holds good in many cases. It is often excesses at the shrines of Venus and Bacchus that are at the bottom of their trouble. True alopecia prematura, that is the type in which clinically no pathological process can be found, is not a common condition. Careful investigation will usually show that the premature loss of hair is due to some demonstrable cause, and this leads to a study of the commonest of such causes, namely, seborrhea.

By this term there is meant an overabundant secretion of skin fat from the sebaceous glands or, according to Unna, from the sweat glands. This view of the process does not correspond with its pathology, because it is not a mere functional disturbance, but rather a slowly progressive inflammatory condition. Alopecia seborrheica occurs in different forms, in the main two, one a diffuse chronic slowly progressive, and the other, acute or subacute and circumscribed. Of the latter but very little is known, so it is of the former only, *i.e.* of the chronic type that mention shall be made.

Seborrhea of the scalp may be either oily or dry. The first named manifests itself by a hypersecretion of fluid fat, oiling the hairs in superabundance and giving them a very fatty glistening appearance. Since the secretion of fat by the skin varies not only in those of different complexion but also in different members of the same race who are of the same complexion and who have the same habits of life, it is very difficult to state just where the line should be drawn between normal and pathological. Aid is here given by the occurrence of seborrheic affections on the forehead, face or other parts of the body, and by an increased loss of hair. This seborrhea oleosa is usually the precursor of the dry form, a sign of which is the mealy bran-like scales shed in a fine shower on the affected individual's clothing and popularly called dandruff.

Investigation of the scalp brings to light a covering of small grayish white scales which can be scraped away easily with the finger nails. The thickness of the covering varies according to the intensity of the process (for it is an epidermal catarrh) and the cleanliness of the individual. To avoid errors inquiry should always be made as to how and when the scalp was last washed.

If during the early stage of the affection the scales are removed there is found an almost normal appearing scalp. Subjective symptoms are, as a rule, not very troublesome—a little itching and feeling of tension, and yet in some cases the itching may be so great that the scalp is covered with scratch marks. Non-observance of this first stage is the usual thing because of the almost entire lack of subjective symptoms, and the great frequency of the so-called innocuous dandruff. The individual first seeks the aid of the physician after the barbers and hair dressers have had their fling at it, and at a time when the loss of hair has become noticeable. Upon being told that the dandruff is at the bottom of the affection the patient generally replies, "Why, doctor, the dandruff can't have anything to do with it because I've had it so long and it is only recently that my hair has been coming out in bunches." That's just the story, for from the almost insidous onset until the loss of hair becomes noticeable there is a lapse of at least many months, usually several years.

How can it be determined whether the loss of hair is greater than the production? Thanks to Pohl-Pinkus it is not such a difficult affair. His teaching is that a diminution in the length of the hair precedes the increased loss. So if in the woman's combings of several days more than one-quarter of the hairs are less than six inches long a pathological process is at work. In men the information is gained by noting whether the ends of the falling hairs are pointed or blunt. If blunt they are so because of the barber's scissors and denote a normal loss; but if more than one-quarter are pointed, there is a pathological loss.

Now to return to the course of the disease again. The amount of hair becomes less and less, especially so at the frontoparietal regions and at the vertex. The scalp shows through its thin hairy covering more and more, and when this stage of affairs is reached it is not long before the individual presents the complete bald head of alopecia seborrheica.

Another relatively common affection producing

*Read before the Albany County Medical Society, November, 1914.

circumscribed loss of hair is that known as alopecia areata. Upon a scalp, to all intents perfectly healthy clinically, there suddenly appears a bald spot of about the size of a ten-cent piece, and either round or oval in outline. At the borders of the patch, if it is extending, the hairs can be pulled out easily, and when these are examined under a low power lens they show atrophied spear point-like ends, the so-called exclaimation point hairs of Crocker. The area may enlarge either slowly or quickly and always by peripheral extension. New patches may form and coalescence take place, producing large bald areas, dead white in color, and with a convex margin. Sometimes it happens that the disease is so extensive that every hair of the head is lost, giving a clinical picture termed alopecia areata capitis totalis. There is no scaring, no redness, no scaling, no swelling; in fact, nothing pathological can be seen except the circumscribed loss of hair.

In the course of a few weeks, as a rule, the bald areas become covered with a fine growth of non-pigmented, lanugo-like hairs, several crops of which grow and fall before hair of normal color, size, and strength is produced. Occasionally the return of hair may be delayed for years, but does finally make its appearance in the vast majority of cases. The more years under forty the individsal is the better the prognosis.

As to the etiology of the disease there has been and still is much controversy. The camp is divided into the neurotics and the parasitics. In support of the former is the work of Max Joseph and others who found that by injuring or removing the second cervical ganglion in cats a patchy baldness ensued, and also the fact that several cases are on record where, in human beings, following injury to the upper cervical ganglion, a condition exactly like alopecia areata has resulted. The parasitics, mainly the French, uphold their side of the controversy with the statement that many epidemics have been observed where there were numbers of people using toilet utensils in common, as in the army barracks in France. The oval or round shape and the increase in size of each patch by peripheral growth might speak for the presence of a parasite, but up to the present time no microscopic finding has stood the test.

This leads to a consideration of the forms of alopecia known as mycotic and produced by vegetable organisms. These are two in number, ringworm and favus, and inasmuch as the cause of the latter was the first to be discovered, it is no more than just that it should be given priority in description.

Schoenlein in the year 1839 announced the discovery of a fungus in favus, and in recognition of his labor Remak named it the Achorion of Schoenlein. The fungus is found in the root sheaths, bulbs, and shafts of the hairy filaments near the scalp. The quickest method of ascertaining its presence is to macerate, for about five minutes, crusts and hairs with a 10 per cent. solution of caustic potash on a glass slide, cover with a cover slip, and examine with a quarter or sixth objective. The intricate masses of spores and mycelium, if present, can readily be seen in great quantity.

Favus is most rare in the native born; its greatest prevalence is in Poland, France, and Scotland. The disease is contagious because the parasite producing it is capable of transmission from man to man, as also from animals to man, and vice versa. The usual course is from mice to cats, and from cats to man. Its presence in an immigrant is cause enough for deportation.

When the anchorion grows on the scalp it gives rise to the formation of the characteristic favus scutla, which are sulphur colored, rounded, cup-shaped crusts, depressed in their centers where the hairs pierce them, and seemingly imbedded into the skin. They can be loosened easily from the corneous layer which covers them and drawn out over the hairs which go through their centers.

The development of these characteristic elements can be easily studied by thoroughly cleansing an affected scalp. In a few days there appear on a more or less reddened scaly area very small yellow points around the follicle openings. These points resemble pustules very much, but are quickly differentiated from such by their solid formation. Later on there takes place a confluence of elements with the formation of friable masses. The scalp now possesses the never failing, characteristic mousey odor of favus.

The hairs in an affected area are not broken off as in ringworm, but they differ from the normal hairs around in their stiff, lusterless, faded appearance.

After the disease has been present for quite some time scars make their bow on the scene. These are due in part to the pressure of the scutula, and in part to the inflammatory processes. The scars are depressed, white, and hairless, becoming larger and larger as more destruction takes place, until finally in an untreated case a cure results when nearly all the follices have been invaded, giving the picture of an almost completely scarred scalp, with here and there a few sprigs of hair standing.

Ringworm has been a much juggled word for centuries. It was used to denote any cutaneous affection in which the lesions were arranged in rings. Ambroise Paré tells us that in France the word teigne, corresponding to the English word ringworm, was used by the vulgar to designate any disease in which "the scalp looks ragged and red, as if gnawed by the moths that eat up garments." It was not until the middle of the nineteenth century that a hard and fast line was drawn around the affection we now speak of as ringworm.

In 1842 Gruby presented to the Academy of Sciences a paper "On a species of contagious mentagra resulting from the growth of a new cryptogram in the roots of the hairs of the beard in man." In it he says, "The microscopic examination of the hair shows that all its dermic portion is surrounded by cryptograms forming a vegetable layer between the sheath and the hair itself, in such a manner that the hair is contained in a sheath exclusively formed of cryptograms like a finger in a glove. They take origin in the hair follicles and in the cells of which its sheath is composed, and they pass upwards to envelope the portion of the hair situated in the skin." This description corresponds to the fungus now known as the trichophyton megalosporon, or large spored.

In 1843 he presented to the same academy an other paper entitled "Researches on the Nature, Seat, and Development of Porrigo Decalvans or Phytoalopecia." He describes porrigo decalvans as "An affection characterized by rounded patches covered with white scurf and small, grayish scales

with falling out of the hair." He furthermore says, "Microscopic examination shows that the hairs are surrounded by a vegetable covering to a distance of one to three millimeters above the level of their exit from the skin. This sheath is formed by cryptograms felted together so as to make a sheath around each hair. The spores are generally rounded, sometimes oval, and measure from 1 1000 to 5 1000 of a millimeter in diameter." To this species of fungus Gruby gave the name of *Microsporon audouini.*

Sabouraud, in our day, has done more work on this subject than any other living man, and yet, notwithstanding the long list of species of the trichophyton that he has cultivated, there need be but two of them mentioned from the clinicians' standpoint, the two described by Gruby in 1842 and 1843.

Ringworm of the scalp is essentially a disease of childhood, but may rarely be seen in an adult. The majority of cases occur in the second half of the first decade of life and sex shows no difference to the liability of infection.

In the small-spored type the initial lesion, seldom if ever noticed, is a small red papule situated about the orifice of a hair follicle. The papule enlarges in all directions and forms a round or oval patch with a scaly surface and a slightly raised edge. From other points of infection other patches may form, varying in size from a quarter of an inch to several inches in diameter. The patches are studded with dry withered stumps of broken hairs, giving the appearance of a field of stubble. Close inspection will show that the hair stumps are not glossy; they are thickened and have a whitened look due to the parasitic sheath surrounding them. The hairs are loosened and can be removed painlessly with great ease. The thickening is due to infiltration with the fungus, which, in its growth, pushes asunder the epithelial cells of which the shaft is built.

The large-spored fungus causes but a small proportion of the cases and the affection is much milder than that produced by the microsporon. The stumps of the hairs have no white sheath and commonly break off at a level with the skin.

Microscopic examination of the hairs, after maceration with caustic potash solution, shows, in the small spored type, the fungus on the outside of the hair in the form of spores arranged in the fashion of a mosaic surrounding the shaft, and inside the hair in the form of mycelial threads. In the large spored variety, the spores are arranged in chains, and the mycelium is short and regularly jointed.

Symptomatic alopecia is a frequent accompaniment of diseases which also attack the skin of the hairy head, like psoriasis, ichthyosis, lichen planus, pityriasis rubra pilaris, and the exfoliative dermatites. Simple inflammatory processes like erysipelas may be followed by loss of hair. Over growths, especially atheromata, there may be no hair. In the vast majority of the above cited conditions the alopecia is only a temporary one. Acne necrotica, atrophic folliculitis, scleroderma, lupus erythematosus, idiopathic skin atrophy, tuberculous, syphilitic, and leprous infiltrations healing with a scar, as well as all ulcerative processes produce permanent loss of hair.

Symptomatic alopecia may accompany or follow the so-called internal diseases which affect the whole organism, like scarlet, measles, typhoid, syphilis, influenza, tuberculosis, acute rheumatic fever, myxedema, chronic mercurial and arsenical poisoning, chlorosis and all anemic conditions. The loss of hair in these states may be merely a symptom of the general under-nourishment, or may be the result of a toxemia acting on the hair papillæ. A brilliant example of the latter is myxedema, for when the detoxicating effect of the thyroid substance fed to those so afflicted begins to exert its action, there is a new growth of hair which remains only as long as the medication is continued.

206 State Street.

THE ROLE OF THE PHYSICIAN IN INDUSTRIAL MEDICAL INSURANCE.

By A. C. BURNHAM, M.D.,

NEW YORK.

Notwithstanding the fact that legislative activity during recent years has led to the enactment of compensation laws by the Federal Government and twenty-four States, and that in most States the medical care of the injured employee is considered a part of the compensation award, it is still true that the average physician has little or no knowledge of the basis and principles of this type of insurance.

Insurance for medical attendance and hospital care is already applicable to a large percentage of the industrial population of the United States and, as it rests upon a sound basis, it may be expected rapidly to extend itself during the next few years. It consequently behooves the members of the medical profession to inform themselves on this important branch of medical economics.

The State control of compulsory accident insurance was inaugurated in Germany in 1884 and since that time has reached a remarkable development in that country as well as having spread to practically every country in Europe. The strongest argument advanced for its being is that shortened lives and maimed limbs due to injuries are just as much expenses of production as are fire losses and broken machinery. From this it is but a short and easy step to the argument that human disability is as much an overhead expense as is machinery repair and that an industry should pay the medical expenses and a living wage to every employee disabled through sickness just as they are obliged to repair worn out machinery and sharpen dulled tools. However, sickness insurance, while fully developed in Germany and some other European countries, has yet to be introduced in America and the discussion here will be confined to the care of accident disability alone.

In such a discussion several principles of compulsory insurance against accident should be borne in mind. In the first place, as is well recognized, this form of legislation is based on the theory of partial reparation and of a division of the loss arising from accidents. The loss is to be shared by the industry (and of course in the end by the ultimate consumer) and by the employee. Instead of employers being liable, as previously, only in those cases where negligence could be imputed to them, they are now obliged to indemnify victims of accidents in every case. This works as a hardship on the employee who is injured through no fault of his own, while on the other hand, the employee who is injured because of his own carelessness or disobedience receives partial compensation for his loss

in earning power instead of receiving no redress at all as was formally the custom.

To overcome the fact that the employee never receives full compensation for his loss, the better type of laws provide that the injured workman shall receive his compensation with a minimum of formality and an absence of friction which was always present in the attempts to secure redress under the old liability laws. It is evident that if the workman were to receive the full amount of his loss or to derive a pecuniary profit from his injury, it would instantly place a premium upon injury, and, in many cases, this would lead to simulation, in some cases even to self-inflicted injuries. The accident insurance laws were therefore intended to be only partially reparative and were not intended to act as a charity or as a gratuity to the injured workman. It is distinctly not intended to make amends for disfigurement or mutilation, but merely to compensate in part for the loss of the earning power of the individual. The medical attendant should not be swayed by sentiment, but should endeavor to put the injured employee into the condition best suited to his individual employment in the shortest possible time. Under this interpretation of the law it is evident that operations for removal of cicatrices for cosmetic purposes have no place in the treatment of cases under the various insurance laws, unless at the same time the removal would tend to increase the earning power of the individual. Thus it becomes clear that a disfiguring scar on the face might be enough to injure the usefulness of one employee, while to the other it would be of no consequence, as far as his earning power was concerned.

The law is not properly conceived as a class law; it is not intended as a means of equalizing the monetary differences between the rich employer and the poor employee and the broadminded physician should not look upon it as merely a method of taxing the rich employer for the benefit of himself and his patient. The physician should realize that it is merely an accident that he bears such an important part in the carrying out the terms of the law. The law was not intended as an aid to the physician, but it speaks well for the profession that he is considered a necessity in the satisfactory execution of most of the laws of this type.

The physician who undertakes the treatment of compensation cases should bear in mind that he is one of the three parties to a contract. The contract which he has entered into is to cure the injured workman and to get him back to work as soon as possible, without prejudice to his health or earning power. The parties to the contract are: (1) the injured employee; (2) the physician, and (3) the employer (indirectly, the State and society in general). It must be remembered that in the end the compensation received by the employee, and the pay for the physician's services comes out of the pocket of the consumer, and that, if a workman is allowed to simulate an injury, it is not the insurance company or the employer but the general public who pay the bill.

Few physicians seem to comprehend this idea of social medical insurance. Disregarding the cases of distinct fraud and malingering, of which there have been many under the various acts, there are still cases where the attending physician seems to have lost sight of the fact that he is working for the State and that his indifference or carelessness is causing society an unnecessary expense.

Physicians frequently allow patients to send in disability reports for a much longer period than necessary, merely because the patient requests it; and patients are often allowed to remain away from work for weeks when their only complaint is a slight pain or tenderness at the point of injury. The treatment of the Colles' fracture is a case in point. It is well recognized that a moderate use of the hand after four to six weeks is usually advantageous after a fracture about the wrist, and yet physicians have reported a complete disability of ten, twelve, or fourteen weeks after such an accident, the patient being allowed to continue treatment for slight tenderness about the joint although he would undoubtedly recover more quickly if at work. Another abuse of the law is that physicians keep their patients coming to the office during office hours and thus preventing the patient's return to work when, as a matter of fact, the treatment could be done as well at another time so that the workman would be free to report for duty. This sacrifice to the convenience of the physician amounts in the aggregate to many thousands of dollars annually.

There have been volumes written upon the abuse of the medical benefits in Germany and other European countries; and, apparently as a result of compensation laws, there have arisen a vast number of new complaints, most of them in the domain of neurology, consisting of various types of "traumatic hysteria" and "traumatic neurasthenia," all of which may be expected to make their appearance in America during the next few years.

Granted that the State undertakes the medical care of industrial workers, what means has it at its command to secure the attendance of the physician upon the injured workman?

The medical attendance may be secured in three ways: (1) By contract, (*a*) Yearly contract, (*b*) Per capita contract; (2) By unlimited choice of physicians; (3) By limited choice of physicians.

Contract services may be secured by the State in one of two different ways. The State may employ a number of full time physicians who will give their services exclusively to the treatment of injured workmen. This is the method in general use in the army and navy and would probably, if carefully planned and kept free from politics, give the workman fairly satisfactory medical attention. It would theoretically include specialists in eye, ear, nose and throat, etc., and probably give workmen in the larger industrial centers a high grade of service. In the smaller towns, however, it would be expensive and often difficult to obtain. Moreover, it would not attract the highest class of practitioners, and it would tend to cause friction between the State surgeons and the medical profession in general. Another type of medical contract is mentioned only to be condemned. This consists in the contract between the State and the physician to give medical attention at so much per capita per annum. This is ordinarily accomplished by allowing the physicians to bid and usually results in a very low per capita payment leading to those abuses which are seen so frequently in the lodge practice contracts of New York City. A modified plan of this sort was instituted in England, and led to a great deal of dissatisfaction.

The second plan for treatment of injured employees is that known as "unlimited choice." By this is meant that the patient has the privilege of choosing any physician he pleases and allowing him

to take care of his injury. Patients soon learn to go to the physician who will magnify the injuries and thus increase the period of disability and enlarge the award. The physician who is conscientious and tries to get his patients back to work as soon as possible soon notices that he has less and less opportunity to care for cases of this type. The policy of unlimited choice of physicians has been instituted by France and has led to almost inconceivable abuses. The following is extracted from an article by H. G. Villard in the New York *Evening Post*, April 12, 1913. In speaking of the establishment of private clinics in Paris he says, "Usually these were started by young and unscrupulous doctors with little standing or practice and indifferent to the established rules of medical ethics. As the Accident Insurance law made the employers responsible for all medical costs and fees, these practitioners foresaw that, once assured of a clientage, their path to fortune was secure. Accordingly, while self-advertising is deemed highly unprofessional in the best French medical circles, the owners of these private clinics have not hesitated to use the most flamboyant and often dishonest methods to attract to their establishments workmen who have been injured in the course of their employment. Drummers and agents are posted and employed near important workshops, whose duty it is to steer injured workmen to, and to extol the merits of these clinics. The clinics themselves are painted in gaudy colors, flaring advertisements are posted in conspicuous places, circulars are sent out and handbills distributed among the working classes. Dressing of wounds, massage, electrical, radium, and mechano-therapeutical treatments are offered. Attention is also called to the fact that attached to the clinic is a legal bureau which will procure the maximum indemnity allowed by law and attend to all formalities prescribed for the procuring of the same. Certain of the clinics have even gone a step further and now bestow a five franc piece on an injured employee when he first presents himself and allow him a daily stipend ranging from one-half to two francs a day so long as he is under treatment. With such inducements held out to them, it is not surprising that the workmen, when injured, flock to these private accident clinics. In Paris, more than half of all accident cases are treated in them.

"The bad results of the provision in the French Accident Insurance law granting to the injured workman the right to select his own physician are thus apparent. The individual practitioner does not benefit, for he finds no accident cases coming to him for treatment. The workmen are demoralized, for they have been taught not to regard an injury or disability as a misfortune, but as a means of making something out of their employers. Hence their readiness to travel even a distance of fifty miles from their places of injury to the clinic that holds out the most inducements. The employers and insurance companies are fleeced at every possible turn, and a heavy burden imposed on French industry in the shape of increased premium rates."

The third manner of supplying medical care is by means of the limited choice of physicians. This method allows the workman to choose his physician from among certain accredited physicians and he usually chooses the physician whose office is most accessible to his residence or place of employment, depending on whether he is, or is not, able to perform some part of his customary labor.

The New York State Compensation Law provides that the employer shall provide satisfactory medical attention and that if this is not supplied the employee may secure his own physician and the employer is responsible for a reasonable charge for medical attention, the only criterion being the financial status of the patient, the law requiring that the physician treating the patient shall take the financial standing of the patient into consideration and modify his bill accordingly. This section of the New York law has already caused considerable dissatisfaction among a large number of physicians.

Many employers have been extremely liberal in the interpretation of this portion of the law and have allowed the injured workman free choice of physicians and this has already led to many of the abuses seen under the French law. Unnecessary calls have been made and enormous bills have been presented for minor injuries. These abuses have been increasing and will no doubt continue to increase as the limits of the law are better understood. It is obvious to most fair minded physicians that it is difficult for the State Commission, which in New York has broad jurisdiction, to determine in every case just how many visits and how much treatment is necessary in a given case. In the end they must make their charges upon what seems reasonable and fair compensation in the case under consideration.

If the medical profession intends to meet its responsibilities it will do all in its power to aid in the suppression of such abuses. If this is not done the cost of medical attendance will rise so rapidly that the State will, of necessity, be obliged to limit the choice of physicians who work under the act to those who have special qualifications and who show themselves willing and able to perform satisfactory services for a reasonable fee.

Under the present law in New York this can be done in one of three ways: Employers may contract for medical services either on a salary basis or upon a fee schedule, or the State may require that only a certain panel of physicians may receive compensation for the care of workmen injured under the meaning of the act. This will be accomplished by the simple method of increasing the insurance premium to those employers who insist on allowing the workmen free choice.

That the extra cost in cases of free choice is a considerable one is shown by the following table showing the average cost of medical attendance in accidents involving temporary disability in France from 1901 to 1911. The law allowing free choice of physicians went into effect in 1905.

Year	Francs	Year	Francs
1901	12.95	1907	17.25
1902	14.	1908	18.30
1903	14.50	1909	19.55
1904	14.80	1910	20.44
1905	15.20	1911	21.58
1906	15.90		

This is an increase of over fifty per cent. in six years. In New York such an increase would cause an extra tax upon industry of approximately $2,000,000* per year and, if the experience of France is any criterion, without a corresponding benefit

*It should be understood that this is merely a rough estimate and is based mainly upon the fact that the State Fund appropiated about $400,000 for the medical expenses for the first six months.

either to the injured workman or the honest physician.

It is, consequently, of extreme importance that each physician who may be called upon to treat patients under the terms of industrial insurance laws should acquaint himself not merely with the legal requirements and probable monetary advantages, but also with the broad economic principles upon which such laws are based and endeavor to make the execution of the medical regulations agree with the spirit and purposes of the principles upon which compensation laws are based.

140 West Seventy-Ninth Street.

HEMATURIA.

By CHARLES J. DRUECK, M.D.,

CHICAGO.

Hematuria (the presence of blood corpuscles in the urine) is always pathological and appears in a number of different conditions. The blood may come from any part of the urinary tract and, while the determination of its source is sometimes easy, at other times it is difficult, if not impossible. Frequently the physician is pinned down by the patient or his friends for a definite diagnosis, and where this differs from what has been previously offered by some other medical man, it disturbs the confidence of the patient. An example of this I shall cite later of a child who had hematuria for about a year which had been said to be due to kidney disease. When I diagnosed cancer of the kidney the family were very skeptical and it was only after the mother felt the tumor that she gained confidence in my judgment.

The character of the blood in the urine and its time of appearance, whether clotted or diffused, profuse or scant, and its relation to the act of urination differ and indicate somewhat the part of the urinary tract involved. The chemical reaction of the urine also affects the color (acid urine is dark red, while alkaline urine containing the same amount of blood will be bright in color). Of course, if the amount of blood is small it may not materially influence the color of the urine. The albumin test will, however, show even very small traces of blood.

Guyon (White and Martin) divides the causes of hematuria into trauma, congestion, inflammation, organic disease, and foreign bodies. Sometimes the pathology seems hardly sufficient to create the disturbance in the case at hand. The amount of blood in the urine is variable. If slight, it may not show macroscopically, but if profuse the urine appears bloody. The microscope is always necessary to verify the clinical picture. If the urine contains pus as well as blood, the blood will be found in the sediment, leaving the liquid part of the urine uncolored.

The more dilute the urine is the less rapidly will the blood clot, but the more rapidly will it diffuse and dissolve. Blood clots in the urine have little diagnostic significance except the long, thin, cylindrical ones. These resemble earth worms in appearance and are formed in the ureter. Short cylindrical clots have no significance. The color of the clots varies from yellowish red to thick, heavy, dark red. The fibrin clots closely resemble broken pieces of cancer tissue.

We will divide the sources of hemorrhage into (1) kidney including the ureter, (2) bladder, and (3) urethra. Enumerate the causes in each division, and see what diffenential picture we can draw.

Kidney.—It has been said that renal hemorrhage is more protracted than the bleeding of the bladder or urethra, but that is uncertain. In all diseases of the urinary tract the periods of bleeding are more frequent and intense as the disease advances.

(a) Chronic diffuse inflammation of the kidney has no hemorrhage.

(b) In the following conditions the hemorrhage is slight and subsides as the other symptoms are relieved; acute parenchymatous nephritis (this is frequently the result or accompaniment of variola or scarlet fever); amyloid degeneration, abscess embolism, hydatids, purpura hemorrhagica, and phlebitis (uterine or crural).

(3) This group in which the hemorrhage is profuse and obstinate includes cystic disease of the kidney, chronic interstitial nephritis (here the hemorrhage frequently alternates with hemorrhage from mucous membranes), malignant disease (hemorrhage here is brought on by slight or undiscernible cause; it is made worse by exercise, but is not much relieved by rest). Guyon says that the hemorrhage of kidney tumor is intermittent. It will stop and then suddenly reappear, the variations occurring frequently. Sometimes the ureter is blocked with a clot and the urine is clear for few hours, then the clot is suddenly released and the hematuria reappears. The presence of renal casts shows positively that the blood is from the kidney. Tuberculosis of the kidney shows an intermittent hematuria which is brought on by exertion, but the urine contains pus and débris which remain in suspension and do not tend to settle out. Pain is also present but is variable, sometimes, however, amounting to a true renal colic. The hematuria of renal calculus is excited by the slightest muscular strain or violence, such as under normal conditions would not cause any disturbance. The bleeding is promptly relieved by rest in bed. There is always more or less pain and renal colic which is reflected from the lumbar region in various directions. The pain of renal colic is quickly relieved by rest in bed, but not the pain of tuberculosis or tumor.

(d) Drugs may also cause hematuria; such are turpentine, carbolic acid, cantharides, and mercury. It must also be remembered that senna and rhubarb cause the same reddish-brown color of the urine simulating hemorrhage.

(e) Trauma.—In severe injuries and malignant disease the blood may be bright red and the hematuria may appear to be terminal. In trauma the location and character of the injury will determine somewhat the source of the blood, *i.e.* a kick in the back followed by hematuria would suggest a contused or lacerated kidney, while a blow on the abdomen and particularly in the hypogastric region would indicate a ruptured bladder.

A heavy dragging sensation due to the renal congestion sometimes precedes hemorrhage from these parts or an attack of renal colic may appear. These pains do not occur with hemorrhage from the bladder or urethra.

Bladder.—Associated with bladder lesions that cause hemorrhage we usually find cystitis and alkaline urine, and if so the mucopus and phosphates so cloud the urine as to alter its appearance and prevent the easy detection of blood. When the urine is ammoniacal the hemoglobin is frequently dissolved out of the corpuscles and the cells are then called shadows. These are sometimes confusing when found in the urine. They appear as small

bodies or rings the size of red cells and have no nucleus.

(a) The hematuria of vesical calculus is terminal and the blood is fresh. The hemorrhage is moderate unless prostatic disease complicates. (b) Prostate cystitis and (c) vesical tuberculosis also have slight terminal hematuria and in this symptom closely resemble stone. (d) Polypi of the bladder and (e) fibrous tumors usually show slight or moderate hemorrhage, but (f) villous growths bleed profusely and the blood forms a reddish-brown sediment. A vesical tumor so long as it is not near the bladder neck may not show any other symptom except hemorrhage and is not palpable in its early stage and thus the hemorrhage is frequently considered renal. Of course, if the colic or some other localizing symptom appears that will determine the course of the bleeding. (g) Varicose veins of the neck of the bladder sometimes rupture and cause quite a sharp free hemorrhage.

A cystoscopic examination must be made in all doubtful cases of hematuria. When the hemorrhage comes from the bladder we have besides the visible blood, frequent micturition, and pain in all inflammatory, obstructive, or traumatic cases. A bimanual examination will frequently detect changes in the bladder wall or prostate or the presence of a tumor. Vesical tumors ultimately necessitate catheterization and then cystitis is soon added to the clinical picture. When the blood is diffused throughout the urine and the last urine contains a quantity of pure bright blood it is probably vesical or prostatic bleeding.

Urethra.—Hemorrhage from the urethra usually precedes the flow of urine and also recurs between the acts of urination, but if it does not it may be squeezed out by stroking the urethra.

(a) Acute gonorrhea, a mild hemorrhage may occur in any case.

(b) Acute posterior urethritis presents only terminal hematuria.

(c) Chancre within the urethra sometimes causes hemorrhage that may be obstinate and recurrent.

(d) Neoplasms and injuries to the urethra sometimes cause a hemorrhage that may be alarming.

In any case of hematuria the signs and symptoms other than those of the urine itself must be considered, because the trouble may be outside of the urinary system. Blood appearing at the beginning of urination (initial hematuria), the later urine being clear, must come from the urethra. If the bleeding is from the prostatic urethra, it may flow into the bladder and in this condition the last urine is often almost pure blood (terminal hematuria).

Treatment.—The great number of causes of hematuria divide themselves into those that must be treated therapeutically and those that can be arrested mechanically. During the bleeding, rest in bed, liquid diet of buttermilk, and diluting drinks to lessen the tendency to coagulation, and the production of a soft free stool. Drugs by the mouth are of doubtful value. Guyon gives turpentine, three drops every four hours for 6 or 8 doses. Ergot in full doses is also recommended; oil of erigeron and gallic acid have also been used. Any of these may be of value in moderate and persistent hemorrhage. In sudden profuse bleeding that threatens to exsanguinate the patient a full dose of morphine to quiet the restlessness and anxiety may be given. Next empty the bladder with a catheter or suction pump as needed and then irrigate with hot antiseptic solution of silver nitrate 1:2,000 or hydratis one ounce to the pint. After this the catheter should be held in the bladder until the bleeding ceases.

If this does not control the bleeding a perineal cystotomy should be performed, all clots removed and a drainage tube inserted. This must be done under the most rigid asepsis because the bladder is very liable to infection after the hemorrhage and particularly so in cases of tuberculosis or neoplasms. Prostatic hemorrhage is often relieved by opium suppositories in the rectum and by suprapubic compresses.

I wish to report a couple of cases that may be of interest at this time.

Case I.—C. H., a boy 12 years old. Four years previously he was vaccinated and from that his parents date his trouble. About two years afterward he suffered a hematuria of slight amount every couple of days for about a month. During this time, the parents say, he appeared otherwise healthy. For the next year he had occasional hematuria, but most of the time the urine was normal. There is no record of the urine at this time except the parents' statement. For about a year new blood has appeared constantly in the urine and has increased in amount until recently it was nearly always present and in large amounts. The urine at best is heavy and smoky brown in color (at times it seems to be largely blood). As his mother says, "it is pure blood that runs from him." During the first year of this boy's illness no positive diagnosis could be made. About six months ago a tumor of the right kidney became palpable and continued to enlarge until it nearly filled the right side of the abdomen. The boy suffered very little pain, only a dragging sensation in the region of the kidney, but grew waxy and anemic. The features were distorted by the anasarca. The boy cut his hand while playing with a knife and although the cut was one and one-half inches long and one-half inch deep it bled no more than a scratch. After his death we did a partial post mortem examination and found the right kidney about the size of a cocoanut and somewhat the same shape. It was soft and boggy, quite friable, and easily crumbled under the fingers. The pelvis of the kidney was filled with a granulating mass, but there was no blood or blood clots. I was surprised at not finding clots or free blood in the pelvis of the kidney and very little on section of the growth. The liver was small and did not present any apparent secondary growths. All of the abdominal organs were very pale. Death was really due to exsanguination. No examination was made of the chest as the parents objected. I was not permitted to take out the tumor, but a section of a small piece showed it to be a sarcoma.

During the time this boy was under my care I went through the whole list of drugs supposed to be good for hematuria, but none had any effect on him.

Case II—Mrs. A. had been a nurse. Following the birth of a baby she was troubled with paresis of the neck of the bladder which persisted after she was up and about. She insisted on catheterizing herself. Later she developed a sharp cystitis with stone formation. Every couple of days she voided bits of calcium phosphate and as these pieces broke away there was considerable free hemorrhage. Sometimes this hematuria would accompany only one urination and again be quite free. In this way it was intermittent but persistent and blood corpuscles could be found in the urine at all times. Of course it had a gradually exsanguinating effect.

I made a vesicovaginal opening and found the mucous membrane sheeted over with this stone deposit beneath which the surface was ulcerated and granulating. Under local treatment and drainage she soon recovered.

Case III—About three years previously I had operated upon this man, 37 years old, for hemorrhoids. They were internal and so extensive that I removed considerable mucous membrane. The result was very satisfactory as far as the operation was concerned and the man has had no other rectal inconvenience since. When the bowels moved first after the operation (on the fourth day) he had quite a terminal hematuria, and ever since then whenever the bowels are constipated and the movements accompanied with straining there is danger of this hematuria. There are no other symptoms of anything. The hematuria is always terminal and persists for the next few urinations. Sometimes it is

quite sharp. It may recur in a couple of days or he may go months without a sign. During the interval there frequently is no blood in the urine. He frequently passes three or four months without any trouble, and once went eight months. The trouble is always brought on by constipation. He is caused so little trouble that he objects to a cystoscopic examination and I have never made one. I believe this is a case of varicosed veins about the neck of the bladder or the prostatic urethra due to my operation upon the middle and superior hemorrhoidal veins when I removed the piles.

THE HOMOGRADE THERMOMETER.

By F. E. ASPINWALL, M.D.,

LA GRANGE, KY.

In the Homograde Thermometer the normal blood heat at or near the surface of the body where sensation mostly exists is the unit of value, and every degree in the scale equals 1 per cent. of that unit. The scale begins with 0 at the freezing point, 270 represents the boiling point of water, and 100 the normal blood heat within the radius of sensation. Figures from 0 upward are placed to the left of the tube; below 0 to the right of the tube. In the clinical thermometer the figures from 100 upward are on the left side of the tube, and from 100 downward on the right side of the tube, 100 being on both sides. This arrangement of the figures not only makes a beautiful thermometer, but facilitates the reading of the record and lessens the liability to error.

Animal heat is correctly expressed in degrees above freezing, for an organism whose temperature is at or below the freezing point can manifest no life. In the Homograde scale 100 represents the human normal and all variations therefrom are expressed in percentages of that normal. This gives a clearer conception of these variations than can otherwise be obtained. Thus 100° H. represents the full normal surface or near surface heat when as far as temperature is concerned there should be perfect comfort; 95° H. expresses 95 per cent. of that heat, a 5 per cent. deficiency; 105° H. expresses a 5 per cent. increase of heat, a moderate and usually not dangerous fever, while 110° H. expresses a 10 per cent. increase of heat, which is high and proportionately dangerous. These figures are thus seen to be remarkably expressive. They are so appropriate that they are not likely to be forgotten. I will state here that I have observed an even 100° H. in the mouth, in the axilla, and even in the palm of the hand when there was full flush of heat and perfect health. Also 105° H. in one-day fever of childhood. It is understood that in health there is often a loss of several degrees Homograde in the surface heat, but any material increase above 100° H. is certainly fever.

Contrast the above figures with those of the Fahrenheit thermometer. The latter are wholly arbitrary, inexpressive, and actually misleading. Thus 102° F. gives little conception of the temperature expressed. Changed to its Homograde equivalent, 105° H., its value is instantly understood. So throughout the scale the Fahrenheit figures fail really to express the temperatures for which they stand, and the value of a Fahrenheit degree is not apparent. Thus 50° F. is not 50 per cent. of anything. In fact, the figure is very misleading, it having been recommended as a medium bath temperature, while its equivalent, 27° H., shows it to be only 27 per cent. of the animal heat, much too low a temperature for a full water bath. The temperature expressed by 50° H. is probably what the writer above referred to had in mind when he wrote "50° F." The Fahrenheit figures misled him. The Homograde figures never mislead. They always appropriately express the temperatures for which they stand. Of the Homograde thermometer it may be truly said: Once used no other will satisfy.

To change Fahrenheit figures to Homograde find the exact number of degrees above or below freezing and increase that number one-half. The result will be the Homograde equivalent. Throughout the Homograde scale there are exactly 3 degrees instead of 2 degrees in the Fahrenheit scale. The shorter degrees of the Homograde thermometer necessitate a less frequent use of fractions.

Medicolegal Notes.

Hypothetical Questions—Effect of Morphine.—In an action for personal injuries it was held that a question asked a physician calling for his opinion as to the mental capacity of a person to transact business on a given day because on preceding days morphine had been administered to him, must state the amount of morphine administered, the method, and times of administering, to enable the physician to determine the effect thereof. —Brown v. Ann Arbor R. Co., Michigan Supreme Court, 140 N. W. 1031.

Consideration for Deed from Patient to Physician.—A deed was made to the grantor's physician in consideration of his agreement to make certain payments of money and to care for the grantor during the rest of her life. In an action by the grantor's administration to have the deed set aside it was held that it was supported by a sufficient and adequate consideration in the absence of fraud, though the grantor died shortly afterwards, and the benefits received by her as a result of the contract were therefore small in comparison with the value of the property conveyed, it not appearing that her early death was expected when the deed was executed.—Silveria v. Alexander, (Cal.) 144 Pac. 303.

Using False Certificate. — The Washington Statute, Rem. & Bal. Code, §8401, provides that every person filing for record or attempting to file for record a certificate issued by the board of medical examiners to another, falsely claiming himself to be the person named in the certificate, or falsely claiming himself to be the person entitled to the same, shall be guilty of a felony. It is held that the filing for record, or attempting to file for record, is a necessary ingredient of the offense, and an information merely charging false personation, in that the accused did wilfully, etc., claim himself to be the person named in and entitled to a certain license to practice medicine, issued to L. and duly and regularly filed by him, when in fact the defendant was not the person named in the certificate, and was not entitled to practise medicine in the State, but failing to allege any attempt on his part to file the certificate, did not state an offense.—State v. Stanley, Washington Supreme Court, 144 Pac. 689.

Expert Opinion Based on Experience. — Physicians were examined as medical experts in a personal injury case, and detailed the facts ascertained by their examinations of the plaintiff, and were then asked: "From your examination, . . . basing your answer on your experience as a medical man and the facts that you have detailed to this jury that you found existed," etc. It was held that this question was not objectionable in so far as it requested the expert to base his opinion on experience as well as on the facts testified to; the word "experience" implying skill, facility, or practical wisdom gained by personal knowledge, feeling, and action, and also the course or process by which one attains knowledge or wisdom and being frequently used as their equivalent.—Chicago I. & L. Ry. Co. v. Gorman, Indiana Appellate Court, 106 N. E. 897.

Privileged Communications — Physician's Record. — Under Wisconsin St. 1913, §4075, relative to privileged testimony, it is held that the record made by the physician who had been treating the deceased prior to the accident causing his death, was properly excluded, in an action for damages, when offered in evidence on the question of the probable duration of deceased's life, but for the accident.—Mahegan v. Faber, Wisconsin Supreme Court, 149 N. W. 397.

New York, May 22, 1915.

EPILEPSY FROM MANY ANGLES.

THERE are few diseases about which so many theories have been evolved as epilepsy. From a retrospect of recent literature alone one may glean a number of the most diverse hypotheses. These may be referred to as the metabolic, the bacterial, the vascular, and the psychic theories of epilepsy.

The exponent of the metabolic theory is S. Kozlowski (*Zeitschrift für klinische Medizin*, Vol. 79, Nos. 3 and 4), who found in the urine in eleven cases of this condition an amount of neutral sulphur seven times as great before the attack as after. This relationship is reversed if the diet is restricted to milk. The exciting factor in epilepsy is attributed to oxyprotein acids formed in the organism as metabolic products of meat and disappearing under a milk or vegetable diet. The periodicity of the epileptic attacks is explained on the basis of a periodically increased excitability of the nervous system, either congenital or acquired.

C. A. L. Reed (*Southern California Practitioner*, March, 1915) advances the view that epilepsy is the result of a specific infection from the intestinal canal. The unknown microorganism is supposed to be a bacillus of gas-forming series, residing first in the duodenum and finally in the colon, and favored in its growth by intestinal stasis resulting from mechanical conditions. The possible rôle of the *Treponema pallidum* in the genesis of epilepsy has been investigated by Petzsch (*Psychiatrish-neurologische Wochenschrift*, Vol. 15, No. 52), who found a negative Wassermann reaction in the cerebrospinal fluid in forty-three cases. In forty-two of these the lymphocytes were not increased, and in one were only slightly increased. The Nonne-Apelt reaction was always negative. A weakly positive Wassermann reaction was obtained with the blood serum in one case; in all the rest it was negative. Upon the basis of this investigation one is apparently justified in denying any possible relationship between lues and epilepsy.

In favor of the view that epilepsy is of infective origin may be cited the studies undertaken by Gerhard Müller (*Sommers Klinik für psychischen und nervösen Krankheiten*, Vol. 8, 1913, No. 3), as to the behavior of the leucocytes in this disease. He found that the attack is accompanied by a general hyperleucocytosis, with a relative increase in the small lymphocytes, the large mononuclears, and the transitional forms, and a relative decrease in the polymorphonuclear cells. The leucocytosis begins several days before the attack and disappears rapidly after the attack.

The vascular theory of epilepsy is favored by I. Bram (*New York Medical Journal*, March 20, 1915), who believes that this disease is the result of an abnormally high intracranial pressure, associated with a sudden increase in the general blood pressure. Venesection is recommended as the method of choice in the treatment of an attack, and the administration of the iodides or of thyroid extract is advised as a supplementary measure.

The influence of the Freudian teachings has naturally extended to this disease. An elaborate thesis based upon these teachings has been framed by L. Pierce Clark (*New York Medical Journal*, March 6, 1915), who finds in the epileptic individual an immature psychosexual phase of emotional development. There are early libidinous fixations on the father or mother (as revealed by psychoanalysis), and "the fit is essentially a libidinous outlet or striving of the unconscious forces, which, though widely variant, yet possess many of the characteristics of the dream language and motive; all the epileptic manifestations are in harmony with each other, flow out of the disease, and are reciprocal and comparable as a whole." Defective metabolism, constipation, mucocolitis, and autointoxication are considered as contributing and existing factors.

From a survey of the above theories, which does not include all that have been advanced within recent years, one is impressed by the fact that almost all of the exponents of these theories seek to incorporate as subsidiary or supplementary factors the essential elements of other theories. The problem is not a simple one. The inference is suggested that epilepsy is based upon a number of morbid conditions, each of which may play a variable rôle, acting a leading part in one case and a minor part in another. The mathematical conception of disease as the function of a number of variables is perceived here as in other domains of medicine.

VACCINE IN THE PREVENTION OF COMPLICATIONS AND RELAPSES IN TYPHOID.

THE value of the prophylactic inoculations of typhoid vaccine is no longer open to question. Its value as a therapeutic agent when the disease has once gained a foothold has, however, been much discussed and opinion is still divided as to its efficacy. In some series of cases the results have been remarkably good, as to both the low mortality percentage and the comparative freedom from severe complications and relapses. Thus Callison (*Am. Jour. of the Med. Sciences*, Sept., 1912) found that in 423 cases, including 38 of his own, where sufficient dosage had been employed, the mortality was but 5.4 per cent. and relapses 6.5 per cent.; whereas in 975 cases at Bellevue and Allied Hospitals for the years 1908-1911 inclusive, treated by usual methods without vaccine, Coleman, who collected the statistics, found a death rate of 16 per cent., hemorrhages in 13 per cent., and relapses in 20 per cent. Callison's

conclusions were that vaccine treatment in typhoid fever will reduce the percentage of deaths and lessen the number of relapses; that complications are less frequent in vaccine treated cases and the original attack seems to be shortened in some cases; and that to give the best possible results vaccine treatment should be instituted as early as it is possible to make the diagnosis, before the patient is exhausted and complications intervene.

A recent meeting of the Rouen Medical Society (British Royal Army Medical Corps) at Stationary Hospital No. 11 (reported in the *Lancet*, March 20, 1915) was devoted to a very instructive discussion of typhoid and considerable attention was paid to the subject of vaccines. Colonel Sir Bertrand Dawson believes vaccines are valuable if used with caution, but inoculation must be commenced early and the vaccine given in large doses—750 million should be given, instead of the usual 200 million with gradual increase to 500 million. He has not found harm to result from the larger doses, and prefers the heterogenous rather than the autogenous vaccine. Colonel Sir William Leishman also prefers the regular army vaccine. Lieut. Wiltshire reported that army vaccine had been used in the treatment of 45 cases at Hospital No. 12 with good effects in 24. Major Smallman considered that the value of vaccine treatment had been amply proven and referred to a series of 235 cases treated in South Africa, some by autogenous and some by heterogenous vaccines, with very low mortality. None of the speakers definitely questioned the value of vaccine treatment in lessening mortality.

Turning to another phase of the subject, Armstrong (*Surg. Gyn. and Obst.*, Sept., 1914), in a paper read before the Clinical Congress of Surgeons of North America, at London, states that recent figures embracing 9713 cases collected in England, Canada, and the United States show that more than one-third of the deaths from typhoid fever are due to perforation. Since the complications are largely responsible for the mortality in this disease, and since the mortality in large series of vaccine-treated cases is far below the average, it seems evident that Callison was right in his conclusion that complications are less frequent in vaccine-treated cases.

After vaccine treatment, as well as spontaneous recoveries, many relapses have been noted. Recently Professor V. Pensuti, who has long been an exponent of vaccine therapy, has reported in *Il Policlinico* a further series of 69 cases treated by vaccines, and a series of 31 cases in which vaccines were used with the idea of determining whether repeated doses, beyond the usual period in which they have been employed, would prevent relapses. In these 31 cases, after having given vaccine in accordance with the usual plan and to a degree which he believed to be sufficient for the cure of the disease, he repeated for some time a daily small dose of vaccine and kept the patients under observation as long as possible after the cessation of fever to notice whether relapses took place. The doses employed were 12,500,000 daily in all cases except those of two small children (aged 5 and 7 respectively), where the daily dose was 6,000,000. These injections were given for 11 to 25 days; the cases were observed for about three weeks after the subsidence of the initial attack, and in none of the cases was there a relapse, though in some there were occasional slight elevations of temperature of four to six hours' duration. Since heretofore relapses have been noted in various statistics in from 6 to 25 per cent. of the cases, it seems quite probable that the prolonged usage of small doses of vaccine could alone have been responsible for the striking absence of relapses in Pensuti's series of 31 consecutive cases.

In view of the enthusiasm for vaccine treatment expressed by so many of those who have had to handle considerable numbers of typhoid patients under the especially hard conditions imposed by war, it seems strange that vaccine treatment as well as prophylaxis has not had a more extensive and impartial trial in our own country. Those who may be stimulated, through consideration of the above facts, to use the method should remember: First, that the earlier the treatment is instituted apparently the greater is its specific action; second, that the dosage should be fairly large from the outset; and third, that the use of the vaccine in nowise contraindicates such other therapeutic measures as the practitioner is accustomed to employ.

WOMAN SUFFRAGE AND THE BIOLOGICAL DIFFERENCE IN THE SEXES.

It may be recalled that a little more than a year ago, so distinguished a scientist and physician as Sir Almroth E. Wright came forth with a diatribe against giving the right to vote to women in his book, "The Unexpurgated Case against Woman Suffrage." He says that the woman voter would be pernicious to the State because she could not back her vote by physical force and also because she has intellectual defects. If the first reason given in his remarkable declaration be true, then a man who is physically unfit is unfit for the franchise. If physical force is to be the only qualification for the right to vote, then of course a very narrow materialistic viewpoint is taken and many of the powers and abilities of women are lost sight of. The second, or additional reason given, namely, that woman has intellectual defects, is satisfactorily explained by Sir Almroth where he tells how woman's mind works entirely differently from man's. It was unfortunate that he called defects what are a different mode of thought and a different way of arriving at a conclusion. He says "Woman is almost without a moral sense in the matter of choosing or engaging herself to political assistance with the view to influencing votes"; and "the suffrage movement has resulted from an excess of female population." This statement is not wholly warranted, if the history and inspiration of the suffrage movement are taken into account.

Here in this country, in the year 1847, a noteworthy event took place, the real beginning of the woman's movement—a woman, Dr. Elizabeth Blackwell, was admitted to the study of medicine. It was not to meet a merely sentimental need that she strove to open the profession of medicine to women, nor was it for the satisfaction of her own

curiosity. Thoughts of ailments and the study of the body filled her with disgust. It was for intellectual and moral satisfaction that she made the struggle. She said, "I soon felt the want of a more engrossing pursuit than the study of music, German, and metaphysics and the ordinary interests that social life presented." This remarkable woman was graduated in 1849, and as she was a leader or pioneer in so many movements, both here and in England, where she later returned to live that we can but briefly mention some of them. In 1848 the Female Medical Educational Society was formed with a view of overcoming the violent opposition to women studying medicine. At the outbreak of the Civil War she founded the National Sanitary Association which played such a large part in providing trained nurses for our army hospitals and putting the profession of nursing on a high plane. She anticipated modern developments by organizing the services of sanitary visitors in the slums of New York. In 1857 she established the New York Infirmary for Women and Children. In 1865 she founded the Woman's Medical College. This first medical college for women was exceptional; it was a pioneer in doing away with the lecture system, in establishing a graded course, and in inviting outsiders, that is members of the faculties of other medical colleges, to conduct its examinations. It had a unique ending; it voluntarily closed its doors as soon as Cornell University offered its better facilities to women for the study of medicine. Dr. Blackwell was a member of the Vigilance Committee who headed off the many attempts made after the Civil War to introduce the European system of State regulation of vice in New York. Today there are but few European cities that have police regulation of vice and their more enlightened citizens are making efforts to get rid of measures which serve only to add more evils to vice and to commercialize it. When Dr. Blackwell felt called upon to oppose State regulation in that she saw its attendant evils, she at first shrank, because of modesty, from doing what she felt to be her duty. She consulted one of the trustees of her college, a Quaker, and he said, "Thee do what thy conscience bids thee."

From this time on Dr. Elizabeth Blackwell, her sister, Dr. Emily Blackwell, and all the other remarkable women that came under her influence moved forward as leaders in work that had never been taken up by men. Higher education for women, suppression of vice, training of nurses, social service work, moral education for children, sex hygiene, teaching of hygiene and sanitation, health education—all of these endeavors were taken up by women who got their inspiration from scientific knowledge. This knowledge moved them, that is it caused a response in them that man seemed incapable of. It was woman's heart and sympathy that pointed the way to the broader social application of medical knowledge for the benefit of humanity. And all this was accomplished without the franchise.

The argument as to whether woman is man's equal is foolish. Woman is different; her characteristics are equivalent in importance to those of man; they are not defects; they fill out the defects in the intellectual and moral make-up of man. Dr. Blackwell went to London and helped to start the woman suffrage movement, and she brought it more enduring inspiration than Dr. Wright seems to understand. She knew about the blindness of new born infants which is caused by gonorrhea; she knew about the ravages syphilis plays with children; she knew about the diseases some innocent wives acquire from their immoral husbands; she understood the social evil. She wanted women to get the vote because she thought, incorrectly we believe, that they might thus overcome many abuses that man had not yet succeeded in abolishing. She recognized that woman was mentally, temperamentally, and biologically different from man. She never made any claim that woman was mentally the same as man. In her "Human Element in Sex" she wrote: "No careful observer can fail to remark the larger porportionate amount of thought and feeling as compared with the total vital force of the individual, which we find given by women to all that concerns the subject of sex. Words spoken, slight courtesies rendered, excite a more permanent interest in women. That which may be the mere passing thought or action of the man, at once forgotten by him, obliterated by a thousand other intellectual or practical interests in his life, often makes a quite undue impression upon the woman. Incidents are thought of, over and over again, and are supposed to mean much more than they do mean. A romance or a scandal, a tale of true or false love will always excite interest, where business, politics, science, or philosophy, will fall upon deaf ears. All that concerns the mental aspect of sex, the special attraction which draws one sex towards the other, is exhibited in greater proportionate force by women, is more steady and enduring, and occupies a larger amount of their thought and interest." One wonders whether, when woman descends to man's sphere and strives with him on the stump and at the polls, this description will still hold good and whether she will not barter the charm of her sex for the ballot. Of course, if she insists upon the suffrage she will get it, for she always gets what she wants, but when she can achieve so much and bring about such great reforms by the simple but enormous power of persuasion, why should she reach for man's coarser weapons.

THE SUPPLY OF RADIUM IN AMERICA.

A CERTAIN amount of confusion appears to exist with regard to the radium supply in this country, though the general idea is that the supply is inadequate. In *Radium* for March is a paper by Dr. Charles Viol who discusses the situation as to radium in this country. He makes and quotes statements which go to show that—(1) The present production of radium in the United States is more than adequate to supply the demand in the country. (2) The selling price of radium is not exorbitant, and the prospects are that the price will rise in time rather than fall. (3) The United States Bureau of Mines has given no proof whatever that the process for radium extraction said to have been devised by

the experts in that Department is at all successful in working up on a large scale the low grade carnotite ore which is at present the visible source of supply in the country. (4) Should the Government authorize the Bureau of Mines to go into the radium business on the scale contemplated in the acts under consideration, private parties and hospitals would not be able to secure such radium at any price until the National Radium Institute and the Government hospitals had been supplied, and to secure such radium would involve waiting about five years. (5) Should the Bureau of Mines be authorized to undertake to produce radium, the result would be practically to establish a monopoly of radium for therapeutic purposes for years to come, since the Government hospitals may each treat only ten patients who are not Government employees.

The therapeutic value of radium, although perhaps somewhat overestimated, has been conclusively proven and therefore the question of an adequate supply at a cost within the means of members of the medical profession is important. At the present time, the cost is prohibitive in all parts of the world to many physicians who would otherwise use it in treatment. This state of affairs is unfortunate and any scheme which would tend to make radium cheaper would be to the benefit of all. Whether then a monopoly of the radium supply, which the writer in *Radium* argues would be brought about by the plans said to be conceived by the Government, would result in increasing the supply and cheapening the cost is a moot point. The writer whom we have quoted thinks it would not have this effect and his opinion is entitled to respect, but the whole matter requires to be thoroughly threshed out, and the Government side heard, before a final judgment is given.

RECENT CONCEPTIONS OF UREMIA.

It has long been surmised that instead of a single condition, uremia, there are uremias; or if not that, one true uremia and several pseudouremias. In true uremia there is a notably high percentage of residual nitrogen in the blood, with general asthenia and dyspeptic disorders. Convulsions are not necessarily present, and are a secondary phenomenon. True uremia is a retention phenomenon. Eclampsia occurring in a nephritic subject does not represent a true uremia, nor does a soporous condition in high tension subjects of advanced years. A nephritic may have serial convulsions, yet be without dyspepsia. These patients usually have tubular nephritis.

These statements were made by Strauss at the United Berlin Medical Societies, session of March 17 (*Muenchener medizinische Wochenschrift*, March 30). In discussion Rosenberg reported on his analysis of 150 cases of nephritis, with following results: there are three types of uremia, to wit: azotemia (the true retention form), with weakness, apathy, narrow pupils, etc.; convulsions without azotemia, with elevation of pressure in the lumbar cord; and finally the uremia found in red granular atrophy. Leschke stated that true uremia could easily be recognized by the increased nitrogen content in the blood and cerebrospinal fluid. Uremia (convulsive) of tubular nephritis is preceded by delayed elimination, instead of absence, in the ferrocyanide test. The vascular, arteriosclerotic, small red kidney type may be recognized by the theocin test, for no diuresis is produced as in the normal kidney. Further, theocin has some therapeutic efficacy if its use is continued.

PLAGUE.

Owing to the European war and to other reasons bubonic plague is now widespread over the face of the globe. According to Dr. W. C. Rucker, Assistant-Surgeon General, United States Public Health Service, writing in *Public Health Reports* for April 16, it exists in California, Seattle, and New Orleans. It has just broken out afresh in Cuba, and in South America the disease was reported only a short time since in Brazil, Ecuador, and Peru. In fact, as said before, the malady is more or less prevalent throughout the world. Plague being essentially a ship borne disease, it is consequently a menace to this country by the medium of its ports. Further, plague is a rat borne disease, and as rats are numerous on ships, the only sure protection against its spread lies in adequate rat proofing. Moreover rats must be excluded and starved. This latter object may be accomplished by poisoning and trapping. If by trapping, the captured rodents should be subjected to a laboratory examination, for by this means it is possible to determine whether or not they are plague-infected and, should any prove so, to take such measures as will prevent the plague from spreading to human beings. This, too, is the most efficient mode of detecting the presence of plague in any seaport, for no seaport can truthfully say it has no plague until a careful survey has been made of its rodent population. But that this scheme may be readily effective it must be done thoroughly by experts. Plague is at the present time world wide. Under existing conditions in Europe and Asia it is likely to spread, and is therefore a menace to every port of the United States. If proper and efficient steps are taken to prevent its ingress into this country the menace will come to naught, but these measures must be applied with scientific zeal to be of avail. This furnishes one more argument in favor of the nationalization of all quarantines, for sanitary surveys of this sort can of course be more effectively carried out if they are conducted according to a definite plan and under one responsible and capable head.

The Antialcohol Society of Munich Physicians.

A perusal of the transactions of this society at its session on January 25 last (*Muenchener medizinische Wochenschrift*, February 8), might, we fear, cause our own zealots, medical and lay, to accuse it of lukewarmness, if not of actual betrayal of their cause. The Munich physicians might even be accused of "going easy" with the hard drinking Bavarians. For while the propaganda of the two countries agree closely in most respects, we find among the Munich type certain leanings toward common sense and away from fanaticism. Thus alcohol is not so much played up as a destructive tissue poison; it is a subverter of discipline, a demoralizing agent. This old and unanswerable

argument has been of late years sidetracked by the chemical poisoning argument. The Munich idea is not so much to attempt to frighten men into sobriety as to appeal to their reason. The occasional references to moderation and caution in the use of alcohol, in sickness as in health, have a strict psychological foundation, for they do not arouse that enmity and resistance which would follow counsels to absolute abstinence; at the same time one reads between the lines that abstinence is the approved course. A large volume of good, sound, sensible advice is given with the aim of securing a nonalcoholic status. There is no extenuation or defence of the use of alcohol; and aspects of the cause, which although of minor importance, nevertheless lead to infinite bickerings, are left out of consideration. No one for a moment can doubt that the Munich physicians are very much in earnest in their attitude in the crusade against alcohol, and one must admire the absence of intemperance which marks their efforts.

News of the Week.

Committee of American Physicians for the Aid of the Belgian Profession.—Report of the Treasurer of Contributions received during the week ending May 15, 1915:

Dr. Franklin B. Miller, Pittsburgh, Pa.	$25.00
Dr. N. S. Jarvis, Captain U. S. A., New York, N. Y.	15.00
Dr. Charles G. R. Jennings, Elmira, N. Y.	23.00
Dr. H. E. Jenkins, P. A. Surgeon, U. S. N., Port Royal, S. C.	5.00
Dr. Luther G. Paul, Boston, Mass.	5.00
Dr. M. C. Smith, Lynn, Mass.	5.00
Arkansas Medical Society, Little Rock, Ark.	50.00
Dr. Charles Henderson Miller, Chicago, Ill.	10.00
Receipts for the week ending May 15th	$140.00
Previously reported receipts	6,720.50
Total receipts	$6,860.50
Previously reported disbursements:	
1,625 Standard boxes of food at $2.20	$3,575.00
1,309 Standard boxes of food at $2.30	3,010.70
Total disbursements	6,585.70
Balance	$274.80

American Association for Promoting Hygiene and Public Baths.—A very successful meeting of this association (the fourth annual session) was held in this city on Tuesday, Wednesday, and Thursday of last week under the presidency of Dr. Simon Baruch. The day sessions were held in the City Hall and an evening session on Tuesday at the Academy of Medicine. Dr. Baruch, in his presidential address, spoke in praise of the efforts of the Allies in the present war to restrict the abuse of alcohol; he said much good would result from the antinarcotic laws in this country and uttered a note of warning against the danger of contracting a drug habit at the soda fountain or through the use of patent medicines; and he urged that public health administration be taken out of the control of politicians, citing the wonderful results of such action in the Canal Zone, and criticising the retention of political supremacy in the quarantine at this port which should be transferred to the efficient control of the U. S. Public Health Service. A large number of papers were read by sanitarians and physicians. The next annual meeting will be held in Baltimore.

Award of the Osiris Prize.—The Osiris prize, amounting to 183,000 francs ($36,600) because no award was made in 1912, has been awarded chiefly for discoveries in medicine, according to an announcement by the French Institute. Dr. Chantemesse and Dr. Vidal will divide $10,000, while an equal amount will go to Dr. Vincent, in recognition of their discoveries in vaccine. Twelve thousand dollars is given to various ambulances and the remainder is placed in reserve.

Transfer of the Boston Quarantine.—On June 1 the U. S. Public Health Service will take charge of the Boston quarantine station on Gallups Island. The property has been leased to the Federal Government for a year at a rental of one dollar, and when Congress meets in December provision will be made for the purchase of the quarantine plant.

Special Trains for San Francisco.—Dr. J. Rawson Pennington, Chairman of the Committee on Transportation of the A. M. A., announces that there will be three special tours carrying physicians to the annual meeting in San Francisco in June. These are: (1) The Gregory tours, including round trip railroad and Pullman fares, seven days in San Francisco hotel, admission to the Exposition, and various trips in and around San Francisco; fare $141 from Chicago, $135 from St. Louis. (2) The McCann special train from New York to San Francisco and return, leaving June 16, stopping at Glacier National Park and other places on the way home, five days hotel room in San Francisco, meals en route, and all expenses except meals in San Francisco; for $280.70. (3) Pennsylvania Railroad tours, the first leaving New York June 11, arriving in San Francisco in time for the Pan-American Medical Congress; the second leaving June 16, arriving in San Francisco June 20; fares, including only round trip railroad ticket and Pullman double berth on special train to San Francisco, $128.40 from New York.

State Medical Boards.—The South Carolina Board of Medical Examiners, elected at the recent meeting of the State Society, consists of Dr. T. Taylor, Charleston; Dr. John Lyon, Greenwood; Dr. E. W. Pressley, Clover; Dr. J. J. Watson, Columbia.

At a meeting of the Utah State Board of Medical Examiners on April 9 the board was reorganized, all the old officers being reelected. They are: *President*, Dr. D. D. C. Budge, Logan; *Vice-President*, Dr. F. W. Taylor, Provo; *Secretary and Treasurer*, Dr. G. F. Harding, Salt Lake. The other members of the board are: Dr. Clarence Snow, Salt Lake; Dr. C. L. Olson, Murray; Dr. F. Straup, Bingham; Dr. C. F. Osgood, Ogden; Dr. A. P. Higgs, Ogden, and Dr. W. M. Stookey, Salt Lake City

Alumni Association, Medical Department, University of Buffalo.—The fortieth annual reunion of this Association will be held on Tuesday to Friday, June 1-5, 1915. The class and fraternity reunion will take place on June 1 and scientific sessions will be held on June 2 and 3. The graduating exercises of all the departments of the University will occur at the Teck Theater on Friday morning, June 4.

The American Proctologic Society will hold its seventeenth annual meeting in San Francisco on June 21 and 22, 1915, under the presidency of Dr. Louis J. Krouse of Cincinnati. The secretary is Dr. Alfred J. Zobel, 518 Shreve Building, San Francisco.

A meeting of physicians and social workers will take place on Wednesday, May 26, at the New York Academy of Medicine to discuss the State law dealing with giving information about the prevention of conception. Dr. A. Jacobi will preside and among the speakers will be Dr. William J. Robinson, Dr. Ira S. Wile, Dr. S. A. Knopf, and Dr. Lydia De Vilbiss.

New York City's Death Rate.—There were 1,609 deaths and a death rate of 14.46 reported during the week ending May 8, as against 1,607 deaths and a rate of 15.01 for the corresponding week of 1914, an increase of two deaths and a decrease in the rate of .55 of a point, which is equivalent to a relative decrase of 61 deaths.

Typhus Fever in Germany.—The American Ambassador in Berlin states that typhus fever exists in ten of the German prison camps in which Russian, British, and Indian prisoners are confined.

Another Sanitary Party for Serbia.—A group of fourteen physicians, students from the Massachusetts Institute of Technology, and sanitary engineers, organized by Prof. W. T. Sedgwick, sailed from this city on the *Athenia* on May 15, on the way to Serbia. They were sent at the request of Dr. Strong, the chief physician of the American Red Cross party now in that country.

Serbia Calls for Health Workers.—The Health Department announces on the authority of the American Red Cross that the Serbian Government is anxious to obtain 150 men to assist in the campaign against typhus fever and other diseases in that country. The men desired should be either young physicians, sanitary inspectors, fourth year medical students, or others specially trained in public health work. The pay is stated to be $175 a month, to be paid by the Serbian Government, with expenses to and from Serbia. With the present information it is uncertain whether the living expenses in Serbia are to be paid by the Government of that country or not. The period of employment is likely to be four months or more. It is probable that appointees will have to leave for Serbia within three or four weeks.

Order Blanks for Narcotic Drugs.—The New York State Commissioner of Health, acting under authority granted by the Legislature, has approved the order blanks required by the Federal (Harrison) law of December 17, 1914; and it will therefore be unnecessary in future to use the Boylan law blanks, if the Federal order blanks are used instead

Examination for Admission to the Medical Corps, U. S. Navy.—The next examination will take place on or about July 6, 1915. Applications, accompanied by the necessary letters or certificates, should reach the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., not later than June 26, 1915. A candidate for appointment in the Medical Corps of the Navy must be a citizen of the United States, between 21 and 30 years of age, and a graduate of a reputable school of medicine. The application must be in the handwriting of the applicant, and must be accompanied by the following certificates: (*a*) Letters or certificates from two or more persons of good repute, testifying from personal knowledge to good habits and moral character. (*b*) A certificate to the effect that the applicant is a citizen of the United States. (*c*) Certificate of preliminary education: The candidate must submit a certificate of graduation from an accepted high school or an acceptable equivalent. (*d*) Certificate of medical education: This certificate should give the name of the school and the date of graduation. (*e*) If the candidate has had hospital service or special educational or professional advantages, certificates to this effect, signed by the proper authorities, should also be forwarded. The applicant will save unnecessary correspondence if he will make sure when submitting his application that the qualifications enumerated above are clearly and plainly described in his letters or certificates.

Examination for Admission to the United States Public Health Service.—Boards of commissioned medical officers will be convened to meet at the Bureau of Public Health Service, Washington, D. C., and at the Marine Hospitals of Boston, New York, Chicago, St. Louis, Louisville, New Orleans, and San Francisco on Monday, June 21, 1915, for the purpose of examining candidates for admission to the grade of assistant surgeon in the Public Health Service. Candidates must be between 23 and 32 years of age, graduates of a reputable medical college, and must furnish testimonials from two responsible persons as to their professional and moral character. Candidates must have had one year's hospital experience or two years' professional work. Candidates also must be not less than 5 ft., 4 in., nor more than 6 ft., 2 in., in height, with relatively corresponding weights. The examinations are: (1) Physical, (2) Oral, (3) Written, and (4) Clinical. Successful candidates will be numbered according to their attainments on examination, and will be commissioned in the same order. They will receive early appointments. After four years' service, assistant surgeons are entitled to examination for promotion to the grade of passed assistant surgeon. Assistant surgeons receive $2,000, passed assistant surgeons $2,400, surgeons $3,000, senior surgeons $3,500, and assistant surgeon generals, $4,000 a year. When quarters are not provided, commutation at the rate of $30. $40. and $50 a month, according to the grade, is allowed. All grades receive longevity pay, 10 per cent. in addition to the regular salary for every five years up to 40 per cent. after twenty years' service. The tenure of office is permanent. For invitation to appear before the Board of Examiners, one may address: "Surgeon-General, Public Health Service, Washington, D. C."

United States Civil Service Examination for a Physiologist.—The United States Civil Service Commission announces an examination for physiologist in the Dairy Division, Bureau of Animal Industry, Department of Agriculture, Washington, D. C., at a salary ranging from $2,500 to $3,000 a year. The duties of this position will be to take charge of investigations in the secretion of milk and will involve a general fundamental study of the factors controlling the secretion of milk. An M.D. degree or a Ph.D. degree in physiological work, and at least four years' subsequent experience in the investigation of physiological problems, are prerequisites for consideration for this position. Applicants must be men only and must not have reached their fiftieth birthday on the date of the examination, which will be June 8. Persons who meet the requirements and desire this examination should at once apply for Forms 304 and 2095, stating the title of the examination for which the forms are desired, to the United States Civil Service Commission, Washington, D. C.

Broke His Legs to Go to War.—The Washington *Herald* relates the case of James Tood, of Saskatoon, Saskatchewan, who was rejected by a recruiting officer because he was bow-legged. A little thing like that, however, could not cool his patriotism, so he had his legs broken and reset to meet the army requirements.

Charitable Bequests.—By the will of the late Mrs. Ada R. Kimball of Philadelphia the sum of $500 is bequeathed to the Oncologic Hospital of that city.

By the will of the late William J. Power of Philadelphia the sum of $5,000 is bequeathed to St. Joseph's Hospital for the endowment of a free bed, $1,000 to St. Vincent's Home and Maternity Hospital, $500 to St. Mary's Hospital, and $500 to St. Agnes Hospital.

By the will of the late Frederick A. Doyle of Philadelphia a contingent bequest of $3,000 is made to St. Vincent's Home and Maternity Hospital.

By the will of the late Chauncey H. Brush of Philadelphia the following bequests become operative by reason of the recent death of his widow: Chestnut Hill Hospital, $52,000; St. Christopher's Hospital for Children, Germantown Dispensary and Hospital, Philadelphia Polyclinic Hospital, College for Graduates in Medicine, Pennsylvania Hospital for the Sick and Injured, Hospital of the Protestant Episcopal Church of Philadelphia, each $10,000.

By the will of the late Josephine Borie of Philadelphia the sum of $2,000 is bequeathed to the Maternity Hospital of St. Vincent's Home and a like sum to the Hospital for Consumptives at Philadelphia and White Haven.

By the will of Henry Ungrich, Jr., of White Plains the White Plains Hospital, St. Luke's Hospital, and the German Hospital and Dispensary of Manhattan and the White Plains Nursing Association receive $1,000 each.

Obituary Notes.—Dr. SHERMAN VOORHEES of Elmira, N. Y., a graduate of the College of Physicians and Surgeons, Baltimore, in 1893, ophthalmologist and otologist to the Arnot-Ogden Memorial Hospital, and a member of the American Medical Association, the New York State and Chemung County Medical Societies, the American Academy of Ophthalmology and Oto-Laryngology, the American Rhinological Society, and the Buffalo Ophthalmological Club, died at the home of his sister in Brooklyn, N. Y., as the result of injuries received in an automobile accident last July, at which time his wife was killed, on May 1, aged 48 years.

Dr. GEORGE H. STOVER of Denver, Col., a graduate of the Denver College of Medicine in 1893, professor of Roentgenology in the University of Colorado, School of Medicine, Boulder, and dean of the school, and a member of the American Medical Association, the Colorado State and Denver City and County Medical Societies, and the American Roentgen Ray Society, died suddenly from heart disease, in Baltimore, where he had gone for treatment for *x*-ray burns, on March 25, aged 44 years.

Dr. BENJAMIN F. STURGIS of Auburn, Me., a graduate of the Medical School of Maine, Portland, in 1863, an assistant surgeon in the Nineteenth Maine during the Civil War, a former member of the House of Representatives and of the Senate of Maine, a former president of the Maine Medical Association, and a member of the American Medical Society and the Androscoggin County Medical Society, and attending surgeon to the Central Maine General Hospital, died at his home, from pneumonia, after a short illness, on March 31, aged 77 years.

Dr. JOHN MUTIUS GAINES of Hagerstown, Md., a graduate of the Jefferson Medical College, Philadelphia, in 1860, died at his home, after a long illness, on March 27, aged 77 years.

Dr. CHARLES FESSENDEN NICHOLS of Boston, Mass., a graduate of Harvard University, Medical School, Boston, in 1870, died at his home in West Roxbury, of heart disease, on April 5, aged 69 years.

Dr. LEWIS E. SAFLEY of Livingston, Mont., a graduate of the University of Illinois, College of Medicine, Chicago, in 1885, died at his home, after a long illness, on March 27, aged 54 years.

Dr. SAMUEL THOMAS CUBBAGE died at Felton, Md., on April 5 at the age of 50 years. He was graduated from Jefferson Medical College in the class of 1895. He served as clerk in the Maryland House of Representatives in the session of 1913.

Dr. DONNELL HUGHES died of pneumonia at Philadelphia on April 8, at the age of 56 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1879 and he served as assistant demonstrator of surgery in his alma mater in 1880-81, and as gynecologist to the Philadelphia Hospital in 1883-84. He was a member of the Philadelphia Pediatric Society, the Philadelphia County Medical Society, and of the Medical Society of the State of Pennsylvania and a Fellow of the American Medical Association.

Dr. JUSTIN C. ELLIOTT died at Ardmore, Pa., on April 8 at the age of 88 years. He was graduated from the medical department of the University of Buffalo in the class of 1851, and he had practised his profession in the city of Buffalo for more than fifty years.

Dr. FELIX THEBAULT RIVAILLES of Wilmington, Del., a graduate of the University of Louisville, Ky., Medical Department in 1905, died at his home from pneumonia, after a prolonged illness, on April 7, aged 77 years.

Dr. ELLERY M. WING of North Anson, Me., a graduate of the Medical School of Maine, Portland, in 1879, a director of the Somerset Hospital, Skowhegan, and a member of the American Medical Association, the Maine Medical Association, and the Somerset County Medical Society, died at his home after a brief illness, on April 5, aged 59 years.

Dr. WILLIAM JOSEPH DOUGHERTY of Beverly Farms, Mass., a graduate of the Baltimore Medical College in 1907, died at his home, after a long illness, on April 6, aged 33 years.

Dr. JOHN BENNETT TYLER of Billerica, Mass., a graduate of the College of Physicians and Surgeons, New York, in 1868, died at his home, on April 5, aged 71 years.

Dr. WILLIAM H. CHRISTOPHER of London, O., a graduate of the Starling Medical College, Columbus, in 1879, a member of the Ohio State Medical Association and the Madison County Medical Society, a former president of the latter, for fifteen years a member of the London School Board, and for some years city health officer, died at his home on April 2, aged 60 years.

Dr. SANDERS L. SWYGERT of Greenwood, S. C., a graduate of the Jefferson Medical College, Philadelphia, in 1885, and a member of the South Carolina Association and the Greenwood County Medical Society, died suddenly from apoplexy while attending a meeting of the State Medical Association at Greenwood, on April 20, aged 55 years.

Dr. JOHN PARSONS of New York, for thirty-one years connected with the Department of Health of the City of New York, died at his home on April 17, aged 73 years. Dr. Parsons was graduated from the College of Physicians and Surgeons, Keokuk, Ia., in 1864, from the Northwestern University Medical School, Chicago, in 1868, and from the Bellevue Hospital Medical College, New York, in 1875, was a veteran of the Civil War and was a member of the American Medical Association and the New York State and County Medical Societies.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

WOUNDS IN THE PRESENT WAR—REPORT ON STANDARD MEAL FOR RADIOGRAPHIC EXPLORATION—TYPHOID INOCULATION—THROAT EPIDEMIC—SEWAGE DISPOSAL—MEDICAL HISTORY OF THE WAR.

LONDON, May 1.

A FORTNIGHT ago I gave you some account of Sir A. Wright's address on wound infections. Since then he has joined with Mr. Burgham, Sir W. B. Leishman and Sir Berkeley Moynihan in producing a memorandum on the subject, which, as these gentlemen are officers in the R. A. M. service, has the appearance of an official document and certainly the importance of many such. Their object is to synopsize the experience obtained in the present war and to supplement it by setting out the chief data furnished by a bacteriological study of the wounds; further, to lay down certain broad principles of treatment for the guidance of those who have not seen the conditions prevailing in this war, or at any rate only an early or a late phase in the course of these wounds. The authors announce their intention to follow up this memorandum by others on antiseptics and on vaccines as soon as they have completed certain researches thereupon. With regard to the characteristics of wounds from projectiles, they differ greatly from those met with in civil surgical practice. Passing through the flesh the projectile leaves generally a torn, rugged track, and, if it meets bone, crevices between comminuted splinters. Mostly, too, foreign substances are carried in, as shreds of clothing or parts of tissues, and then there are, too, blood clot and effused lymph. Last but not least microbes (*a*), the streptococcus invariably present, we may say, ready to set up suppuration or erysipelas, cellulitis, or septicemia; (*b*) the tetanus bacillus, which if it grows freely and elaborates enough of its toxin, causes the disease tetanus; (*c*) the *Bacillus aërogenes capsulatus* of Welch, which will generate a gas phlegmon and a gaseous gangrene.

To prevent the grave results of the anaerobic infections the memorandum lays down that the wound should be freely opened up and carefully cleansed with antiseptics; all foreign bodies, sloughs, and blood clot (as far as possible without risk of hemorrhage) being removed. Then a very wide drainage tube is to be inserted to admit air to the interior and steps taken to promote the outflow of lymph, especially in cases where there is much laceration. When war conditions prevent surgical measures or when from the nature of the wound it cannot be effectively drained nothing should be done which could favor further infection. Thus (*a*) wounds should not be sewn up after operation—it is never certain that the projectile has not carried in microbes; plugs should not be left in to hinder free discharge; wrapping up must not be airtight; mouths of drainage tubes must be kept open, and so on. (*b*) Pending opening of the wound prophylactic measures, such as antitetanus serum injections. (*c*) Injection of vaccine containing other combined microbes—that of Welch and the streptococcus. But all such methods are only ancillary to the imperfect cleansing and drainage which may for the moment be the only possible course.

A report of a sub-committee of the Medico-Chirurgical Society (electrotherapeutic section) on a standard opaque meal for radiographical examinations of the alimentary canal was presented at a meeting on April 16. It advises that the meal (either porridge or bread and milk) should be about one-half a pint in bulk, mixed with two or three ounces of barium sulphate or bismuth oxychloride; should be taken when the stomach is as empty as possible; no aperient or other medicine within 36 hours of the first examination and if the bowels have not acted on the morning of examination an enema should be given. Precise directions for preparing the meal are laid down, but one member of the committee seemed to think them unnecessary and recommended an emulsion of bismuth carbonate 4 ounces with sugar of milk and water two hours after the ordinary breakfast without purgative or enema. Dr. Hertz said barium sulphate was cheaper than the bismuth salt and just as good, as Guy's Hospital had found, and effected a saving of £50 per annum. Flavoring was mentioned, but it was thought better to leave a free hand about this, tastes differ so much. The president hoped the proposed standard would be generally accepted for the sake of comparison of results.

In the House of Commons a series of questions have been put with reference to inoculation against typhoid. They generally represent the fanatic antis but so far they do not seem to have impressed the House or the public.

The question of selling alcoholic drinks in the refreshment rooms or at the bars has also caused some vigorous expressions of differing opinions. It was declared that the consumption has been surprisingly low. An instance is quoted of two days' consumption amounting only to the cost of 4 shillings.

Violent sore throat has been epidemic of late, and very contagious. It is so frequently followed by cerebrospinal meningitis that some are talking of it as an early symptom of that disease, probably because the organism finds an excellent soil for its growth in the fauces. The contagiousness they attribute to carriers who are unconscious of their impending illness for some days after the germ has established itself or whose constitution may successfully resist its malign influence.

The Royal Commission on Sewage Disposal has issued its final report. They were appointed in May, 1898, and during the sixteen years since they have issued nine interim reports. The last seems at a first glance to give a summary of conclusions and recommendations already discussed.

It has been decided that a medical history of the war shall be published and a strong committee has been formed to write it. The president of the committee is the Director General of the Army Medical Service.

OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

A PERMANENT LEPROSY BOARD—CONTAGIOUS DISEASES ON AN ARMY TRANSPORT—A WATER SHORTAGE—CHAIR OF MEDICAL JURISPRUDENCE AND ETHICS IN THE UNIVERSITY—MEDICAL GRADUATIONS—PERSONAL.

MANILA, March 25, 1915.

IN view of the recent agitation regarding the care, diagnosis, and treatment of lepers and leper suspects, a permanent board to investigate and report upon these matters has been appointed by the Secretary of the Interior. It consists of Dr. J. A. John-

ston, bacteriologist of the Bureau of Science; Dr. Mercado and Dr. Ordway, with Dr. F. Calderm as chairman and Drs. Luis Guenero and Gevasio Ocampo as honorary members. The first three members are to conduct all clinical and microscopical examinations of lepers or leper suspects, and the decision of this board is to be final. If a suspected leper is found to be negative to microscopical examination he is to be isolated under the observation of this committee so long as the latter may require. When a declared leper, after a certain period of treatment, is found to be negative both clinically and microscopically, he will not be considered as cured until two years have elapsed since the date of the first negative examination, provided that all subsequent examinations were negative for leprosy. When a patient is declared to be completely cured he is to be given a certificate to that effect, but with the understanding that he is to be subject to re-examination for leprosy at any time in his residence by the committee or other authorized persons, for the continued protection of the community. All examinations of lepers and leper suspects are to be made hereafter in the San Lazaro Hospital, with materials to be supplied by the Bureau of Science. An appropriation is asked for for the construction of detention buildings for leper suspects and for separate cooking facilities for them and for declared lepers. As some abuses have developed from the authority for special cases to receive treatment in Manila, this matter is also taken up, for many lepers are anxious to remain in San Lazaro Hospital, where they can see their friends. The leper board now proposes to limit the total number of cases in San Lazaro to 100 at any one time, and will determine the cases which should be transferred to Culion. Also private physicians have heretofore been allowed to treat leper cases at San Lazaro. Hereafter, no private physician will be allowed to treat more than one case at a time—and no case will be kept at San Lazaro more than three months under treatment unless in the opinion of the board such case demonstrates improvement. All unimproved cases are to be transferred to Culion. That this board will prove an effective agent for the handling of a very troublesome problem cannot be doubted, especially since its composition thoroughly commends it to the confidence of the Filipino people.

The transport *Sherman* which recently arrived here with a large number of troops, had a choice lot of contagious disease cases aboard, including scarlet fever, measles, and mumps. Altogether 84 cases had occurred during the voyage. The passengers were isolated, over a thousand soldiers were sent to the quarantine camp at Fort McKinley, the ship was disinfected, a new crew put aboard, and the old crew sent to Mariveles quarantine for detention. The case was of particular importance as scarlet fever has never yet gained a foothold in the Islands, and experience in Cuba and other tropical places indicates that if once established its ravages would be very fatal and extensive. Measles, also, is important to exclude, for while the disease has existed here, it tends to die out and extension results chiefly from the introduction of new strains of the disease of an originally high virulence.

After suffering from the floods of last summer Manila is now suffering from a water shortage. The rainy season, while severe while it lasted, ended two months earlier than usual and the mountain streams are unusually low. The city engineer has recommended the construction of a 100,000,000-gallon reservoir, to cost about a million pesos, to tide over such periods of emergency. In the meantime water is being pumped into the mains at Santolan from the polluted Mariguina supply. It is being treated with chlorine in the proportion of 1:1,300,000, and a constabulary guard has been established as a sanitary patrol along the banks of the river to prevent its contamination as much as possible. A general appeal to householders to limit the use of water and stop watering lawns has been made.

A new chair of medical jurisprudence and ethics has been established in the medical department of the University of the Philippines, and Dr. Sixto de los Angeles, a prominent Filipino physician who is a member of the legislature and chairman of its Committee on Public Health, has been selected for the position. He has tendered his resignation as a member of the legislature. The new position pays a salary of 4,000 pesos per annum, with the right to outside practice.

Medical institutions of learning are now graduating their annual classes. The University of Santo Tomas recently conferred the degree of Doctor of Medicine on 27 candidates. The Philippine Training School for Nurses has just graduated 57 nurses, of whom 10 have announced their purpose of taking up sanitation and district nursing and of taking a post-graduate course in the school to that end. The willingness of such a number of nurses to leave Manila is very encouraging, as heretofore provincial work seemed unattractive to them.

Colonel Charles M. Gandy of the Army Medical Department, has recently reported here for duty as chief surgeon of the Philippine Department. He is an old-timer here, this being his third tour in the Islands, and he finds here many old friends.

2. Rare Type of Bladder Ulcer in Women.—G. L. Hunner describes a group of cases in which the lesion differs in many respects from the so-called Fenwick ulcer which has been the type heretofore designated as simple ulcer. The ulcers have been found in women, but probably also occur in men. No cause for the lesion could be learned from the history. The ulcers have all been found in the vertex or summit or free portion of the bladder, this being one important distinction from the simple solitary ulcer of Fenwick which is found on the base or fixed portion of the bladder. An important characteristic is the extremely slight mucous membrane change found in certain periods of the ulcer. While cystoscopy usually reveals only one inflammatory spot, there may be two or three granulation areas near together or somewhat separated, and operation usually reveals a more extensive area of inflammation than is appreciated by cystoscopy. The ulcer area may be easily overlooked and the attention may first be arrested by an area of dead white scar tissue. In the neighborhood of this scar-looking area one sees one or more areas of hyperemia which, on being touched with a dry cotton pledget or with the end of the speculum,

bleed and first show their character as ulcers. In other cases, or perhaps at subsequent examination on the same case, the ulcer may be well defined as a deeply red area with granulating base and with congested vessels surrounding the area. In none of these cases has an individual ulcer area been more than a half centimeter in diameter, although two or three such ulcers have at times been grouped in a larger inflammatory area. At certain examinations the central inflammatory area is found surrounded with a fairly wide area of edema. The cystoscopic picture reveals the granulation surface as on the same general level as the surrounding mucosa; in other words, one would describe these ulcers at cystoscopy as being superficial. A diagnosis of this peculiar form of bladder ulceration depends ultimately on its resistance to all ordinary forms of treatment. The best treatment is excision through a suprapubic extraperitoneal route.

3. **Epididymotomy for Acute Epididymitis.**—A. H. Crosbie and A. Riley state that epididymotomy invariably gives immediate and permanent relief of pain. There are no recurrences after operation unless there is a fresh infection. The course of the epididymitis without question is shortened, as is also the urethritis. Patients are probably less likely to be sterile. Treatment of the urethritis can be begun much earlier. The operation can be safely and successfully done in an outpatient clinic under local anesthesia.

6. **Myxedema Simulating Nephritis.**—W. D. Reid reports a case of this condition in a woman, aged sixty-nine years. The case in its final state resembled chronic nephritis mostly by the general aspect of marked edema and the small trace of albumin often present. Among the strong points aiding in the correct diagnosis were the absence of hypertrophy of the heart, of increased blood pressure, of casts or of nephritic changes in the fundi. The trophic changes in the hair, teeth, skin, and nails; the generalized edema, with but slight pitting; the erythematous patches on the cheeks, and the hebetude, deafness, changed voice, chilliness, and absence of perspiration—were all consistent with the diagnosis of myxedema. The history of severe hemorrhage after extraction of a tooth was suggestive of thyroid deficiency. The result of thyroid therapy was conclusive.

1. **Radical Cure of Errors of Refraction.**—W. H. Bates maintains as the result of his animal experiments that the lens is not a factor in the production of accommodation. Hypermetropic refraction is always produced by a strain of two or more of the recti by electrical stimulation or advancement, and is always prevented by relaxation of these muscles by tenotomy. Myopic refraction is always produced by a strain of two obliques and is always prevented by relaxation of these muscles by tenotomy. Atropine prevents, when injected deep into the orbit, the experimental production of errors of refraction. The cause of all errors of refraction is a strain to see. The cure is accomplished by relaxation, which is secured by central fixation. The subjective symptoms of central fixation include the ability to see one part of a letter or other object better than the rest of it; maximum vision is thus obtained and the eyes feel at rest. The objective symptoms indicate no error of refraction by simultaneous retinoscopy and no corneal astigmatism by the use of the ophthalmometer, while the optic axes are parallel, with no squint or muscular insufficiencies (heterophoria). The subjective symptoms of eccentric fixation include the ability to see letters or parts of letters better outside the point regarded; the vision is always defective; monocular polyopia is frequent; and pain and fatigue are usually felt. The objective symptoms always indicate an error of refraction by simultaneous retinoscopy, usually some corneal astigmatism by the use of the ophthalmometer; the optic axes are seldom parallel, squint heterophoria, or muscular insufficiencies being present. The refraction of newborn children is not always permanent. All errors of refraction are produced by muscular action and are usually acquired. Observations of the lensless human eye indicate that the absence of the lens does not prevent the production of errors of refraction by a strain of the extrinsic muscles. The optimum is a letter or some other object which can be regarded with a minimum of strain, and when looking at such an object the patient has no error of refraction by simultaneous retinoscopy. In treatment, the author would discard glasses as soon as possible. He would educate the patient in the fundamentals and stop twitching of the eyelids by pressure on the sides of the base of the nose. Central fixation is obtained by eye training with the aid of the Snellen test card at twenty feet and by alternately practising central fixation with a dot or a fine point at twenty inches or nearer. The results are said to be good. After central fixation is obtained, all errors of refraction are cured.

5. **Nephrolithiasis.**—G. E. Macklem states that though the presence of renal calculus is most frequently noted between the ages of twenty and thirty years, it is encountered at any age, uric acid infarcts having been found in the newborn. The precipitation of salts in the urine is usually preceded by a catarrh of the renal tubes, brought about by a highly acid condition of the urine. Calculi are more frequently encountered in the right kidney than in the left, owing possibly to its being more freely movable, and stones in kidney and ureter of the same side, and stones in both kidneys and ureters are not infrequent. Pain constitutes the most prominent symptom in the average case; the severity of this pain depends upon the roughness and movability of the stone, rather than upon its size. The extent of the disease should never be graded by the lack or presence of symptoms of unusual severity, especially pain, as cases are very frequent in which the subjective symptoms are few or are replaced almost entirely by those of a reflex character, and yet an almost total destruction of the kidney may have taken place. In practically every case blood cells can be found in the urine immediately upon the cessation of the attack of colic. Cystoscopy is not indicated in this class of cases, until the diagnostician is positive that the case is not one of renal tuberculosis in which the bladder has not become involved, as it occasionally gives rise to traumatism that is sufficient to act as a predisposing cause of vesical tuberculosis where the bladder was free from involvement before the examination. The medical treatment of this condition can only be symptomatic and palliative, but should be given a fair trial unless the case becomes an emergency one.

1. Nutrition and Growth.—L. B. Mendel states that growth receives its impetus in a general way from two distinct sources: the internal factor or inherent growth impulse, and the external factor, which includes, among other agencies, the food supply. The author confines his discussion to the latter. He and T. B. Osborne studied the rôle of the individual proteins and amino-acids in growth by giving an artificial ration of what they have termed "protein-free milk." This consists of the dried residue of milk after removal of fats and proteins. It contains, aside from traces of unremoved proteins, all of the milk sugar and inorganic elements along with small amounts of incidental components, most of which remain unknown, yet evidently furnish an essential non-protein factor to the diet. On mixtures of "protein-free milk," sugar, starch, and purified fats along with selected isolated proteins, young white rats (and in some cases mice) have grown to maturity and have in turn produced young even in the third generation. The catalogue of the individual proteins with which, in suitable concentration, normal growth has been secured, at least for considerable periods of observation, if not until completed maturity, includes: proteins of animal origin—casein (milk), lactalbumin (milk), ovalbumin (hen's egg), ovovitellin (hen's egg); and proteins of vegetable origin—edestin (hemp-seed), globulin (squash-seed), excelsin (Brazil-nut), glutelin (maize), globulin (cotton-seed), glutenin (wheat), glycinin (soy-bean), cannabin (hemp-seed). Failure to induce growth has attended the trials with legumelin (soy-bean), vignin (vetch), gliadin (wheat or rye), legumin (pea), legumin (vetch), hordein (barley), conglutin (blue or yellow lupin), gelatin (horn), zein (maize), and phaseolin (white kidney bean). Both lysin and tryptophan are necessary as constructive units in growth. The author concludes that it is not unlikely—to speak conservatively—that there are at least two "determinants" in the nutrition of growth. One of these is furnished in the "protein-free milk" which insures proper maintenance even in the absence of growth. When this was fed the authors have maintained rats without growth for very long periods. Without this "determinant" (as, for example, in diets of isolated food substances containing artificial substitutes for "natural" protein-free milk) the special components of butter fat or cod-liver oil or egg fat induce only limited gains at best. Another "determinant" is furnished by these natural fats (or fractions more recently prepared therefrom by Osborne and Mendel or the saponification product of McCollum and Davis). Either determinant may become "curative."

4. Tetanus and Antitetanic Serum. — E. E. Irons notes that from animal experiments and the results in veterinary medicine it is evident that antitetanic serum will save animals in which tetanus has already developed. Clinical observations and carefully compiled statistics of tetanus in man indicate that the course of tetanus can be modified and in many instances life saved by proper use of antitetanic serum. The frequent delay in giving antitoxin, after symptoms of tetanus have appeared, the complications of sepsis in lacerated wounds, the occurrence of late death from indirect complications, and the totally inadequate methods of use of serum have served to cast doubt hitherto on the curative value of antitetanic serum. The frequently employed method of giving small doses subcutaneously every few hours and gradually increasing the dose as the symptoms advance disregards entirely the pathogenesis of the disease, is wasteful of an expensive remedy, and is usually without therapeutic result. If the patient is seen early, before fatal intoxication of the central nervous system has already occurred, prompt neutralization of all free toxin in the circulating blood by large intravenous injection, and the neutralization of a part of the toxin already in the central nervous system by intraspinal injection, combined with the judicious use of sedatives and other indicated medical and surgical measures, will save a considerable number of patients who would otherwise die.

7. The Necropsy as a Public Service.—L. B. Wilson points out that some physicians entirely lack an interest in necropsies because they are not interested in accurate vital statistics and in problems of heredity in disease, or because they do not appreciate the value of the necropsy in the correction of errors in diagnosis. Possibly some also hesitate to bring their diagnoses or operative procedures to the test of publicity in the necropsy. Most intelligent laymen will respond to the argument that they ought to know the weaknesses of the members of their own families, but this argument is frequently omitted or greatly subordinated by the physician proposing that a necropsy be made. Usually necropsies are asked for as a favor to the physician, and rarely offered as a favor to the relatives. The policy of the desirability of checking diagnoses and the results of operative procedures by the necropsy findings and of presenting to the relatives the desirability of their knowing the exact cause of death and the presence of intercurrent diseases has been followed out in the Mayo Clinic for many years. As a result, during the triennial period 1910-1912, 626 deaths, 512 necropsies were made, or 81.8 per cent.; in 1913 there were 269 deaths and 227 necropsies, or 84.4 per cent.; in 1914, 293 deaths and 258 necropsies, or 88 per cent., while to date (March 17) in 1915 there have been seventy-three deaths with seventy-three necropsies, or 100 per cent.

13. Lead Neuritis from Cosmetics. — L. R. Sante states that it has long been known that the presence of lead salts, chiefly lead carbonate, in face powder may cause every form of chronic lead poisoning, including gastroenteritis of obscure origin, jaundice with cramp-like abdominal pain, and the characteristic peripheral neuritis. The author reports two cases illustrating the last condition.

14. The Contractility of the Heart.—M. B. Leviton concludes that the contractility of the heart muscle varies within wide limits, depending on the pathological process. This can be fairly well estimated clinically and is a valuable differential and prognostic sign. The findings on auscultation and percussion vary after exercise. Heart muscle may react in three ways: in functional and early lesions the heart boundaries may on exercise return immediately to normal, bruits disappear, and

normal tones at once replace them. In moderately severe cardia) and particularly cardiorenal) cases the boundaries may return to normal, not immediately, but after rest in bed. (The heart may be enlarged and yet retain elasticity.) Should a heart respond at once, even moderately, one may expect at least better response after rest in bed. The heart remains permanently enlarged and inelastic not only after the exercise test but even on prolonged rest in bed.

1. Wound Infections.—Sir A. E. Wright devotes his fourth and concluding contribution on this theme to the subject of vaccine therapy. The prophylactic employment of vaccines is not only the best from the theoretical viewpoint but is also the method which in practice gives the maximum of advantage. As regards the prophylactic inoculation of "antisepsis vaccines" the author believes that if used in combination with physiological drainage one may hope to stave off infection in a fairly large proportion of cases. In those forms of infection occurring in connection with projectile wounds, vaccines give exactly the same dramatic effects as in the small wounds of civil life, the only difference being that when the irruption has been beaten back one has in the case of projectile wounds still the original focus of infection to deal with, and unless one improve the condition of the wound one must always be upon guard against a renewal of the irruption. When there is in a wound quite unobstructed mechanical drainage (such, for instance, as is proved by amputation without flaps) there are from the point of view of the immunologist conditions exactly parallel to those which obtain when microbes make a first irruption into healthy tissues. In other words, one has here, and probably also where there is good physiological drainage, brought to bear upon the microbes an ample force of phagocytes in conjunction with a rapid, as the case may be, percolating or outflowing stream of lymph. As a consequence, vaccines give in these cases results which are so strikingly favorable as to arrest the attention of every beholder. It is not unreasonable to think that the "antisepsis vaccines" might aid the surgeon in his conservative management of imperfectly drained wounds. In septicemias supervening on wound infections nothing can as yet be expected of the antisepsis vaccines beyond their possible prophylactic value.

2. Ileus Duplex.—W. Sampson Handley proposes this name for a condition in which as the result of a pelvic peritonitis there occurs obstruction of the intestine at two points: (a) in the ileum at a point about 3 feet above the ileocecal valve, and (b) in the sigmoid colon at the junction of its iliac and pelvic portions. These are the points at which the ileum and colon respectively cross the brim of the true pelvis. Peritonitis of the serous surface of the intestine, when it reaches a certain degree, is accompanied by complete paralysis of the involved segment of intestine. General peritonitis means general paralysis of the intestine, and is accordingly not amenable to surgical treatment. But if the peritonitis is partial, though unlimited by any adhesion barrier, certain segments only of the intestine are paralyzed. If the paralyzed segments can be thrown out of circuit by surgical measures recovery is in such cases possible and even likely. Unfortunately in these cases the surgeon's hand has been paralyzed by a facile assumption based upon the general abdominal distension that general peritonitis is present. The observations the author has made in the operating theater and the successful results of his cases show conclusively that septic ileus of pelvic origin is not accompanied by general peritonitis when it first comes under observation, and that it is perfectly amenable to surgical treatment, subject to a clear recognition of the fact that two segments of the bowel are involved and that accordingly two obstructions require to be circumvented.

5. On Wound Infections; and on Some New Methods for the Study of the Various Factors which Come into Consideration in Their Treatment. Sir A. E. Wright.

3. The Mixed Typhoid, Paratyphoid A, and Paratyphoid B Vaccine.—A. Castellani states that the mixed typhoid + paratyphoid A + paratyphoid B vaccine may be prepared according to various methods. The simplest mixed vaccine consists of an emulsion of typhoid + paratyphoid A and B bacilli killed by heat, or by adding ½ per cent. carbolic acid without heating, and standardized so that 1 c.c. contains approximately 500,000,000 of typhoid bacilli and 250,000,000 each of paratyphoid A and B. Of this vaccine 0.5 and 0.6 c.c. is given the first time and 1 to 1.2 c.c. the second time, a week later. The mixed vaccine is harmless, does not give a severer reaction than simple typhoid vaccine, and the inoculated persons develop protective substances for the three diseases. In the author's opinion, in countries where in addition to typhoid fever paratyphoid A and B occur, the mixed vaccine should be used as a matter of routine instead of the simple typhoid vaccine. This has been done in Ceylon since 1905 with good results.

Digestive Disorders Due to War Bread, and Their Treatment.—Von Noorden admits that on all sides medical men have been listening to complaints of all kinds about the rye-potato war bread. It is true that such complaints have been for the most part silent, *i.e.*, went no further; still many of them have reechoed to the present time and it is very evident that numerous bakeries have been at no pains to make war bread palatable and digestible. Those individuals who have organic diseases of the digestive organs are not included, because at most with them it is a matter of wheat-rye rolls or toasted bread, which are fully equivalent to antebellum wheat bread. The rye-potato bread tends to set up, in those of sound as well as of weak digestion, *diarrhea*—as a result of fermentation which still persists in the feces. The subjects are naturally heavy eaters of white bread who consume to-day 400 to 500 gm. daily of war bread. Such individuals bolt their food, and all they need is to cut the daily ration in half and masticate thoroughly; as a result of which their troubles rapidly disappear. A few of these sufferers were victims of latent achylia gastrica. The second disorder is hyperacidity of the stomach in subjects with normal secretion under the old régime. We can only

explain these cases by the unusual pabulum as a result of which the sensitive stomach reacts by secretion, having a greatly increased content of acid. As it is hardly expected that these stomachs will learn to tolerate the new diet, the best we can do is to administer small doses of sodium bicarbonate until war bread is a thing of the past. The third disorder noted is flatulence, by far the most common result of eating war bread. We see this condition spread epidemically as if by imitation (mass-suggestion). These individuals as a rule have become addicted to the finest kinds of wheat flour products, which require little mastication. Hence, they do not sufficiently chew the coarse rye bread especially when it is fresh. The chyme, with fragments of bread, cannot be dealt with by the pancreatic amylase. Shreds of bread thus become a culture bed for intestinal flora; while the cellulose itself, so largely present, readily ferments. Nevertheless, tolerance develops in these subjects which in part explains why original complaints cease. The author regards blood charcoal as an extremely valuable remedy for this condition and uses it for several weeks in succession in large doses. The fourth disorder from war bread, to wit, constipation, is rare, and due perhaps to other factors. Instead of treating it we seek to correct it by giving foods known as "feces formers."

Cerebral Physiology and Its Services in War.—Rothmann refers naturally to the abundant opportunities for the study of cerebral localization from the results of wounds involving the cortex, etc., with especial reference to the more exposed frontal area and speech centers. For example recently an infantry man, aged 37, received a tangential wound of the left lateral aspect of the frontal region. Eight days later a peculiar akinesia of the right arm was noticeable. In attempting to grasp anything he miscalculated in certain directions, and there was also a suggestion of agraphia. The assumption was of an injury of the second frontal convolution. The patient showed confusion and failure of memory. After enlargement of the wound and removal of a speculum of bone, the patient instead of improving, became worse and a motor aphasia developed. The dura was then freely exposed and incised, and a cavity opened in the second frontal convolution which contained a blood clot and cerebral débris. First, the akinesia and speech disturbances disappeared, and next the sensorium disappeared. There still remained an uncertainty of grasp, the hand being carried too far to the right. This condition usually points to a lesion in the second convolution, provided certain phenomena are absent, and the more decidedly if agraphia and akinesia coexist.

Typhoid Immunization and Allied Subjects. — This number of the *Wochenschrift* contains no less than nine papers on these subjects. Von Tabora, writing on the treatment of typhoid at the front, alludes to progressive feeding as the best course, condemns baths and approves of a carefully devised plan of pyramidon medication with cool ablutions. Too low blood pressure is antagonized by digitalis. The resulting tonicity of the arteries serves as a prophylactic in dangerous complications. The author's mortality was 4.7 per cent., the low figure attributable largely to the use of digitalis. The socalled cumulative effects of the latter may or may not be visible in the persistent action of the drug long after its suspension. Rhein, of the same service, sought to abort typhoid by intravenous injection of dead bacilli. No bad effects were seen and in about half the material an abortive influence was noted, as estimated by a number of criteria. Mathes and Rannenberg have long been at work on a digestive product of typhoid bacilli. Pepsin was used at first, and more recently trypsin, while nothing could be done with pepsin products, trypsin has been shown to produce digestive products which can act like a vaccine. It is thermastabile, free from bacilli and gives a bacteriolytic immunity. Toenniessen reports on prophylactic immunization of 1,780 individuals, each of which received three injections. In the great majority the general reaction was slight, in the rest sharp. The reaction came on either after the first or second injection, never after the third. In two cases of general reaction venous thrombosis developed, exactly as in true typhoid. It may be that the action of living and dead bacilli is in this respect the same. Such reports are extremely rare and the patients soon recovered without permanent injury. There were two other patients inoculated in the incubation period. One died of a profuse intestinal hemorrhage, the source of the latter being ordinary typhoid ulcerations. The natural explanation of this case is that inoculation came too late to head off the disease. However, the author feels obliged to discuss in advance any claim that the injection could have contributed to the fatal, incoercible hemorrhage. This patient had received two injections, the last having been negative. The second was very promptly followed by the fever, as often happens in immunization. The case at present is unique and further observations of the same nature will be required to solve the mystery. The other patient was immunized while in the midst of an incipient typhoid. He received three injections, the last of which caused a severe reaction, the case ending fatally. Autopsy showed that he had been suffering throughout from a paratyphus fever. The part played by the injections is obscure. Such cases cannot be attributed to the direct action of the vaccine. Weichardt of the same clinic states that certain subjects are naturally abnormally sensitive to the typhoid endotoxins. He emphasizes that there must be technical improvements all along the line in antityphoid immunization. In peace material certain doubtful subjects can easily be weeded out, but soldiers already represent selected material. Schlesinger has immunized 1,340 subjects and makes careful analyses of the local and general phenomena produced. Several weeks must elapse before patients are immunized, and the protection may be short lived. But if typhoid develops after vaccination it is milder rather than more severe than the average. The chief duty at present is to prevent the more disagreeable concomitants of inoculation. Loewenfeld describes a rapid method of bacillary diagnosis. Several such are mentioned, all of which depend upon rapid blood cultures with special resources. The fact of previous inoculation does not interfere with this kind of test, as it does often with the Widal agglutination, and the result is arrived at more promptly.

April 6, 1915.

Poisoning with "Gas Bombs."—Lewin states that private communications have increased in regard to the necessity for troops to inspire explosive gases. The whole matter resolves itself into the toxic action of carbon monoxide. Research has shown abundantly that no other known toxic substance has so great a range or variety of toxicity. It exhibits a malevolent destructive energy toward everything which lives; the injuries which it causes are functional, damaging both mind and body. It is an ingredient of explosive gases, but to what extent? The laboratory work of the au-

thor and Poppenberg has shown that the gas given off in picric acid explosions is 61.05 per cent. carbon monoxide; while in trinitrotoluol it is 57.01 per cent. We may contrast these figures with the less than 1 per cent. of CO in coal dust and the 6 per cent. in illuminating gas. A percentage of ¼ of 1 in the atmosphere greatly damages the red corpuscles, 60 per cent. of hemoglobin being chemically altered. Thus explosions in mines in which the gas produced is rich in CO are deadly, but only because the miners cannot reach a lighter and pure stratum of air. In cases of fire damp this gas has killed at a distance of several miles. In warfare enormous amounts of CO are set free in "free air," but it is a great error to assume that the latter renders the gas harmless. Powder gas is sometimes evident in wounds, the blood of which shows the characteristic changes due to CO. Powder gas contains from 3 to 10 per cent. of the latter. The affinity of CO for red blood cells is 210 times as large as that of oxygen. Men also succumb to CO in sea fights. Experiments were once carried out by bombarding old ironclads within which dogs had been placed, with no intention of injuring them. The gases set free caused functional traumatisms, such as loss of memory of a retrograde character. Dogs failed to recognize their masters. Apathy, disorientation, and disturbances of special senses were also noted. Similar isolated experiences have been seen in man.

Fatigue and Exhaustion. — C. Jacobi refers to war conditions, as a result of which one man persists in his efforts and becomes a temporary hero while another collapses and is regarded perhaps as a quitter. Some of the latter, however, may have been half-starved when they were called upon while others may have been undernourished—even tuberculous. However, exhaustion means more than a high degree of fatigue. A difference obtains here in regard to protein and carbohydrate insufficiency in utilization. If ordinary energy food (carbohydrate), is not available the organism must draw upon protein food, and protein tissues, for energy supplies. In other words muscular tissue is consumed to supply heat and energy. This means exhaustion, structural and functional, and anything short of this situation may be conceived of as some degree of simple fatigue. The author is throughout at much pains to discriminate between the highest degrees of fatigue and exhaustion. The former appear to be associated with a particular condition of the circulation, which in theory should respond to stimulation. The milder degrees of fatigue may be offset by the use of the caffeine substances used under the form of coffee, tea, cocoa, kola, etc. These stand in close relationship to the xanthin group. From another angle, the vascular indication may be filled by suprarenin and hypophysin.

Deutsche medizinische Wochenschrift.

April 1, 1915.

German Army Bread.—On March 6 at the Hygienic Institute, Berlin, a number of eminent men discussed the newer developments along the line of bread economics. Among those present were Rubner, Flügge, Klemperer, Ewald, Zuntz, von Noorden, Baginsky, Rosenheim, Albu, Boas, A. Schmidt, Strauss, Magnus-Levy, Neumann, and numerous others. All pertinent branches of science and art were fully represented. At the close of the discussion Citron stated that the majority of those present had agreed that the recently legalized wheat bread was unacceptable to a small number of patients with gastroenteric affections. The bread in question is 90 per cent. wheat to 10 per cent. rye. Granting that in saving a certain amount of wheat the rye addition works harm to a certain number of people, Citron states that rolls which contain 67.5 gm. of pure wheat flour will not only save so much wheat, but will not irritate the gastroenteric tract. At the same time there is no violation of the law. This is only a suggestion, based on the fact that the 75 gm. roll is made of mixed flour. Naturally, the patient loses 7.5 gm. of each roll, but this loss he can endure. Michaelis condemns rye-flour-potato bread outright. Cardiac and gallstone subjects, and the aged, bear this badly, on account of the flatulence caused. He questions at present the need of wheat flour economy; but as soon as this need is demonstrable, the substance should be saved up for the sake of the invalid. Fürbringer believes that wheat and potato flour make a better bread than wheat and rye flour. Gottstein refers to the part played by home baking in the manufacture of war bread. Should the regulation bread not agree it is provided by the law that home-made bread may be obtained from the community. Boas discusses a bread made of potato flour and skim milk which makes up in availability that which it lacks in palatibility. The gastroenteric disturbances should not be ascribed to diet alone, but to army life in general. Flügge, the chairman, mentions real and imaginary patients in connection with diet. It is the business of the army surgeon to discriminate here. This author, like numerous others, knows nothing of a real shortage of wheat at present. Germany used to be exposed to this contingency but this is not necessarily the case at present. In fact the rye, rather than the wheat, may need conservation. A wheat consumer cannot yet be shown to be a traitor to his country; but a rye flour consumer may already be a dyspeptic. Ewald states that potato flour enters into the composition of so-called "aerated bread" in England, and much more fully than in any of the German war breads. He ate some of this bread when in England and has even fed it to the sick and none objected. The home-made bread of the United States is a simple affair and can be readily made by German housewives. Kuttner gave the standardized war bread to hyperchlorhydrics and achlorhydrics; it disagreed in both cases, although no reason could be assigned. The hyperchlorhydric suffered mostly in the stomach, the achlorhydric in the bowels. Probably the very small pores of the war bread have something to do with it. The author and Loeb made a research into the digestibility of war bread by pepsin and trypsin, and have also used the same bread in trial breakfasts. In the artificial experiments the new and old breads show no difference in digestibility. But in trial breakfasts the chyme from army bread is much more lumpy and frothy than that from ordinary bread. Umber mentioned a very aggravated series of cases of organic stomach disease in which the army bread was well tolerated. He ascribes this result chiefly to good baking. Schmidt mentioned the great toleration of the gastroenteric tract to nutriment of all kinds; notwithstanding which a certain number of subjects known as chronic dyspeptics could not use army bread without both subjective and objective disturbances. Rubner states that there have been many complaints of army bread, but that he has yet to see a victim of it. We must not forget, however, that ordinary bread is often poorly baked. Rye bread in general gives off butyric acid in the intestine. The socalled coarsely milled wheat, asserted to contain valuable ingredients, tends to escape by the bowel in the form of indigestible cellulose. Baginsky insists that in many ailments of the gastroenteric tract with their secondary cardiac and renal disorders only the very finest wheat flour should be used. Albu claims that for the healthy, army bread is sufficient.

Insurance Medicine.

INSURANCE OF CHRISTIAN SCIENTISTS.

To the Editor of the Medical Record:

Sir:—Should we not enter protest against the issuance of life insurance policies to Christian Science believers? It stands to reason that individuals who will not seek help in early affections of the heart, lungs, or kidneys, will allow their condition to go on until they are beyond help. As a consequence the rest of the policy holders must suffer for their neglect.

My plan would be to insert a clause in the policy which makes the granting of the same dependent upon the employment of medical help in time of need.

Barnet Joseph, M.D.

Operations on the Gall-Bladder in Relation to Life Expectancy.—Dr. W. S. Harpole, Medical Director of the Old Colony Life Insurance Company, Chicago, in a paper read before the American Life Convention, discusses operations on the gall-bladder in relation to life expectancy. That there has been an increasing frequency of operations on the gall-bladder, he says, is very evident to all. Everyone has had patients undergo cholecystostomy for indications that would not have been recognized fifteen years ago. He has secured no figures in percentages of increase, although he has made an effort to do so, but no surgeon or hospital has given him figures that would show the percentage of increase relative to other operations. The best he has obtained is from W. J. Mayo, who says in a personal communication: "In going over our statistics I find that the growth of gall-bladder surgery during the past seven years has been very great, increasing from 421 operations in this clinic in 1907 to 981 operations during the year 1914." There are undoubtedly two reasons for the increase of operations on the gall-bladder. First, the more recent knowledge that cholecystitis is sometimes the cause of disease in other organs, as diseases of the heart, the kidneys, the pancreas, the nervous system, and of systemic conditions as high blood pressure. Thus many operations are done without sufficient evidence of gall-bladder disease and only with the hope that exploration of this viscus may reveal a hidden focus as the cause of the distant trouble. Secondly, the technique of these operations has so improved that drainage of the gall-bladder is simple and a relatively safe procedure.

The increase in the number of cholecystic operations brings many more cases to the attention of life insurance companies because of the increased number of operations done and because more are done on men than formerly. In former times cases showing unmistakable gallstone colic were hardly within the limits of insurability. The Medico-actuarial Investigation shows that those who gave a history of two or more attacks of gallstone colic were among the most hazardous risks, giving a mortality of 195 per cent. of the expected. There are only three physical states and three occupations listed in this investigation that show a higher mortality. The six classes showing greater mortality are: (1) Intemperate habits at indefinite times in the past without treatment, 205 per cent. of the expected mortality. (2) Pulse rate over 100, 205 per cent. (3) Working miners, surface miners, 208 per cent. (4) Young men, stone cutters, 214 per cent. (5) Working miners, underground, 226 per cent. (6) More than 50 per cent. overweight, 228 per cent. Reports show that the prognosis of the operative gallstone case is fair, but the studies have covered only short periods of time, and observations in the next twenty years will be enlightening. After surveying the status of operations on the gall-bladder, the writer brings up the subject of prognosis and the question of what attitude must be taken with regard to operative cases. Only two authorities of recent years are found who have made rules or arbitrary limits for these cases. Homer Gage, doubly qualified to speak as he is a surgeon in large practice and medical director of a large company, gives his conclusions in gallstone cases as follows: "In all cases it is, of course, essential that a very full and accurate statement of the conditions found at the time of the operation and the condition of the applicant's health since the operation should accompany the application. If no unfavorable conditions were found at the operation and no signs of recurrence have since been observed, it would seem that after two years a proposal for insurance might be favorably entertained whether the gall-bladder was removed or not. But if the operation were upon the common duct, the interval should be longer." The second opinion is that of Julius Flesch, who says, "A simple cholecystostomy with evacuation of the gall-bladder is no assurance that gallstones, empyema, or cholecystitis will not return. If the radical cholecystectomy is done and during the operation no changes in the ductus choledochus are found and the liver is found of normal size, and after the operation an interval of at least three to five years has passed the application may be considered. The writer's own conclusions in the main agree with the conservative attitude of Flesch.

Complications of Infectious Catarrhs.—Dr. R. A. Young points out that those who have had any experience of vaccines in the treatment of organisms in the respiratory tract know how extremely difficult it is to get rid of them, and therefore some of these repeated attacks of so-called influenza may be reinfections by an organism of which the individual has been the carrier, or they may be due to a succession of different organisms causing successive attacks. The fact that the influenza bacillus is so rarely found nowadays seems to show that there is for the time being, at any rate, a temporary immunity. One point which should be considered is the importance of the cardiovascular complications of infectious catarrhs. Young considers that many of the so-called examples of cardiac over-strain supposed to result from athletics and from over-exertion are really only the result of too early exertion, too early indulgence in games, after one of these infectious catarrhs.

From an insurance point of view there are two facts to be considered. First, what should be done with an individual who comes with a history of a recent attack or who has a catarrhal attack at the time of examination? Secondly, if we get a history of repeated attacks of influenza, obviously it should direct special attention to the condition of the heart and lungs, but is it justifiable even with a history of repeated catarrhal attacks to impose an extra premium upon the risk, apart from finding some demonstrable change in one or other of the vital systems of the body?—Life Assurance Medical Officers Association.

Book Reviews.

THE COMMONER DISEASES, THEIR CAUSES AND EFFECTS. By Dr. LEONHARD JORES, o.ö., Professor der allgemeine Pathologie und pathologischen Anatomie an der Universität Marburg Authorized English translation by WILLIAM H. WOGLOM, M.D., Assistant Professor in Columbia University, Assigned to Cancer Research; Assistant Pathologist to St. Luke's Hospital, New York City. Price, $4.00. Philadelphia and London: J. B. Lippincott Company, 1915.

THIS book is a collection of lectures published by Jores originally for the aid of his pupils. It aims to present as a coherent whole the post-mortem findings of the diseases considered with their sequelæ and their more usual complications. The subject matter is collected into thirty-four chapters which present as many diseases or groups of diseases. It is more than a strictly pathological volume, however, for the author has paid particular attention to the pathological physiology, and while there is no pretention to a listing of symptoms these are introduced to a greater or less extent. Pathogenesis and etiology are discussed sufficiently to clarify the picture. The defect of the work is the one inherent in any collection of lectures, that the presentation is of necessity a brief one and leaves many questions unanswered. Nevertheless, it is likely to prove of value to both the physician and the student. The press-work on the book is of a high grade and the illustrations, many of which are colored, are numerous and excellent.

URGENT SURGERY, By FÉLIX LEJARS, Professeur Agrégé à la Faculté de Médecine de Paris; Chirurgien de l'Hôpital Saint-Antoine; Membre de la Société de Chirurgie. Translated from the seventh French edition by WILLIAM S. DICKIE, F.R.C.S., Surgeon North Riding Infirmary, Middlesbrough; Consulting Surgeon Eston Hospital. Third English impression, with 20 full page plates and 1086 illustrations, of which 729 are drawn by Dr. E. Daleine and A. Leuba, and 198 are from original photographs. Vol. I., Introductory, Head, Neck, Chest, Spine, Abdomen. Price per volume, cloth, $7.00 net; half morocco, $8.00 net. New York: William Wood & Co., 1914.

THERE are many surgeries, in fact, there are far too many books that masquerade under that title; but in Lejars' "Urgent Surgery" we have a work that has a definite *raison d'être* and is the unquestioned leader in its field. Originally written at a time when this division of surgery was very inadequately covered, and furnishing not only an authoritative and practical but also an extremely interesting presentation of the subject, this work soon attained an enviable popularity which has steadily grown with each succeeding edition. At the present time this work has been translated from the French into at least seven other languages and is recognized as a standard throughout the world. Extended comment upon the seventh edition of such a work is obviously unnecessary; but it does seem appropriate to say for the benefit of the new recruits in medicine and surgery that nowhere else, other than by actual experience, can such an insight into this branch of the surgeon's work be obtained.

In this edition there has been a thorough revision of the entire book and such a remodeling of the text as to allow the incorporation of five new chapters (Acute Dilatation of the Stomach, Acute Pancreatitis, Obstruction of the Mesenteric Vessels, Sigmoiditis and Perisigmoiditis, and Dislocations of the Pelvis), and still keep within practically the same space limits. The work now conforms to the latest teachings in practically every respect, the text remains a model of clearness and conciseness, the numerous illustrations are of unusual excellence and all to the point, and it requires no bearded prophet to foresee a still further increase in the popularity of Lejars' "Urgent Surgery."

OPTIC PROJECTIONS Principles, Installation and Use of the Magic Lantern Projection Microscope Reflecting Lantern Moving Picture Machine, by SIMON HENRY GAGE, Professor of Histology and Embryology, Emeritus, Cornell University, and HENRY PHELPS GAGE, Ph.D. Fully illustrated with plates and with over 400 test-figures. Price, $3.00. Ithaca, New York: Comstock Publishing Company, 1914.

SINCE the remarkable development of modern methods of projection the use of the lantern has become so general in medical teaching that a new guide to the proper handling of the modern forms of apparatus is welcome. This volume, however, includes much more than mere practical directions; it is really a complete study of the mechanics and optics of the projection lantern with chapters on the preparation of lantern slides, on drawing with projection apparatus, and on the theory and practice of moving pictures; it contains in addition descriptions of many interesting lecture room experiments for the demonstration of optical phenomena. There is appended an historical summary, a list of manufacturers and dealers in optical and electrical apparatus, and an excellent bibliography of the chief works on optical projection. The book should prove very valuable to those who are using the lantern in connection with teaching.

THE SALVARSAN TREATMENT OF SYPHILIS IN PRIVATE PRACTICE, With Some Account of the Modern Methods of Diagnosis. By GEORGE STOPFORD-TAYLOR, M.D., M.R.C.S., and ROBERT WILLIAM MACKENNA, M.A., M.D., B.Ch., Physicians to the Liverpool Skin Hospital. Price, $1.50. New York: Rebman Company, N. D., 1914.

THIS manual may be unqualifiedly recommended to the practitioner. The authors' material in three years of private practice furnishes the subject matter. Public cases are hardly amenable to successive years of control. It is seldom in any book that we find individual and general experience so intimately interwoven in a small compass. The booklet is at the same time a summary of the most recent acquisitions in the diagnosis and treatment of syphilis, and a concise record of personal experience in the practical application of the same. The authors are warm partisans of the salvarsan treatment of syphilis, and the eighteen "before and after" photographs show what may be accomplished by the drug within a short time, with or without the collateral action of mercurials. Like good Britons, the authors give Donovan priority in the arsenic-mercury treatment of syphilis. The dark side of salvarsan therapy receives little consideration in this optimistic and personal work.

THE BACKWARD BABY. A Treatise on Idiocy and the Allied Mental Deficiencies in Infancy and Early Childhood. By HERMAN B. SHEFFIELD, M.D., New York, Fellow of the New York Academy of Medicine and the Am. Med. Assn.; author of "Modern Diagnosis and Treatment of Diseases of Children," "Pediatric Memoranda," and "The Baby's Record and Health," and co-author of "Practical Pediatrics," etc. Awarded the Alvarenga Prize of the College of Physicians of Philadelphia, July 14, 1914. With twenty-two original illustrations in the text. Price, $1.00. New York: Rebman Company, 1915.

THIS brochure of 184 pages was awarded the Alvarenga Prize of the College of Physicians of Philadelphia. It aims to present an account of the mental deficiencies of children under five years of age. The prenatal and postnatal causes are discussed and the methods of examination and the means of recognizing the different types of mental deficiences are described. The special groups of amentia, including microcephalus, hydrocephalus, paralytic amentia, amaurotic family idiocy, mongolism, cretinism, infantilism, and "moramentia" (a word coined by the author to signify retarded mentality) are delineated. The concluding chapters deal with prophylaxis, eugenics, care of the newborn, mental training of the normal infant, the active treatment of amentia, general hygiene, training by "incentive" method and physical therapeutic measures, organotherapy, thyroid transplantation, drugs, and surgical procedures.

AUGENVERLETZUNGEN IM KRIEGE UND IHRE BEHANDLUNG. Mit einem Abriss uber die Diagnose und Behandlung des Trachoms von Professor Dr. C. ADAM, Priv.-doz. für Augenheilkunde in Berlin, Während des II Balkankrieges Dirigierender arzt der Augenabteilung des Militärhospitals in Belgrad. Mit 40 Abbildungen. Price, Marks 2.50. Berlin and Vienna: Urban & Schwarzenberg, 1914.

THIS little volume of 96 pages is a fairly comprehensive monograph on the subject. Part I is directed to a general consideration of the effect of gunshot wounds on the eye. Part II deals with injury to the various parts of the eye in logical order. Part III is devoted to examination and diagnosis. Part IV to the therapeutics of these injuries. There is a short chapter devoted to trachoma. The work is well illustrated; it is intended for the use of the surgeon in the field as well as the oculist.

Society Reports.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

109th Annual Meeting, Held in Buffalo, April 26-29, 1915.

(Special Report to the MEDICAL RECORD.)

(*Concluded from page* 837.)

SECTION ON MEDICINE.

Wednesday, April 28, Second Day.

DR. JOHN A. FORDYCE OF NEW YORK IN THE CHAIR.

THE morning session was a joint meeting with the Section on Syphilis.

Pathology of Syphilis.—Dr. JOHN A. FORDYCE presented this paper. He believed that in order to combat successfully the syphilitic invasion it was important not only to be informed as to the possibilities of the therapeutic agents but to have a thorough knowledge of the nature of the infection, the reaction which it called fourth in the tissues and the resulting changes which followed. It must be borne in mind that during and even before the secondary period of the disease the organisms were in the general blood and lymph streams and located themselves at this time about the nutrient vessels of the aorta, in bone, in the central nervous system, in the glomeruli of the kidney, or in other viscera. The special tissue selected by the spirochetes might be purely accidental or possibly might be governed by affinities for the strain. While confirmatory laboratory evidence up to now was far from satisfactory, there were certain clinical reasons for the belief that special strains had different invasive powers and might limit their activities to one set of tissues. Patients with syphilis of the nervous system, as a rule, denied the secondary rash. The subjects of extensive skin syphilis were not often afflicted with nerve syphilis and patients with luetic osteitis and periostitis were not so often afflicted with skin lesions. The important factors to be kept in mind were the possibilities of the disease in the secondary period as related to the destructive and incurable lesions which manifested themselves years afterward. If spirochetes were deposited about the vasa vasorum of the aorta in the secondary period of syphilis, they might yield to the natural defenses of the body or be reached by specific drugs. They might be completely destroyed or their activities only delayed by imperfect medication. In the latter case it might be years before the changes in the aortic walls were sufficiently advanced to cause symptoms or physical signs. When such changes were recognizable it might or might not be possible to influence the condition by specific treatment. The early inflammatory reaction about the vessels had produced sclerosis in the vessels' walls, and to these changes was added the mechanical action of the heart on the weakened walls of the aorta. The same held true of the nervous system. Investigations during the past twelve years had shown that the nervous system was invaded early in the disease, probably at the time of the spirochemia, that a meningitis was produced which might manifest itself clinically during the secondary stage or remain latent for a long period, or prepare the soil for an extension of the process or new invasion in later years. It had been estimated by different workers that involvement of the central nervous system in the secondary stage took place in from 20 to 80 per cent. as shown by abnormal findings in the spinal fluid. Dr. Fordyce's own opinion was that no larger percentage of luetic individuals showed changes in the spinal fluid than later developed frank disease of the nervous system. In a series of his clinic and hospital cases of early secondary lues punctured less than 20 per cent. evidenced any abnormality. Whether as Nichols had suggested that in nerve syphilis they were dealing with a specially invasive strain of organisms or whether the choroid plexus acted as a filter or barrier to the spirochetes, he was not prepared to say. They might find analogies in tuberculosis and typhoid fever in both of which diseases the organisms circulated at times in the blood, but only rarely were found in the spinal fluid. In human syphilis inoculation was followed either by a local reaction at the point of entry of the organisms or the spirochetes gained access directly to the blood and lymph stream without producing any demonstrable change *in loco*. In the first event the spirochetes found lodgment in the interepithelial lymph spaces and from here reached the perivascular lymph spaces, where after becoming acclimated to changed nutritional conditions they multiplied. Even now a reaction was taking place on the part of the fixed connective tissue cells in this vicinity which increased in intensity until the height of the second incubation period with the full development of the chancre. The macroscopical appearance was varied. In one case only a herpetic lesion might be present, in another a papule or a slight erosion, and again the classical Hunterian chancre, or its clinical characteristics might be entirely masked by a preexisting chancroid or other cutaneous lesion. It was difficult to say whether this multiformity was dependent upon the immunity mechanism of the patient, the number of organisms, or upon the strain of the spirochetes. Noguchi found certain definite differences in the morphological character of different strains isolated. This led him to divide the various specimens into the thicker and thinner forms and an average or normal form, the last being the most common and frequent. He found that the lesion in the testicle of the rabbit differed according to the variety inoculated consisting either of a diffuse or a nodular type. Nichols also found that a strain isolated by him from the central nervous system presented different biological properties, without being in a strict sense of the word neurotrophic. He applied to them the quality of invasiveness based on the production in rabbits of lesions of the scrotum and testicle which were hard and necrotic in the center and a generalization of the infection as evidenced by lesions of the eye and skin. The organisms were thick in form and had a short incubation period corresponding to the thick type described by Noguchi. These results were of particular interest in view of the occurrence of syphilis of the nervous system in individuals infected at the same source, and the not unusual occurrence of conjugal and familia syphilis. The attempt of Jakob and Weygandt and others to produce a neurotrophic strain in rabbits had not given uniform results, some rabbits showing a pathological condition of the nervous system, others not. Noguchi came to the conclusion that it was necessary to previously sensitize the animal in order to obtain involvement of the nervous system. Just how soon after inoculation in the human subject the spirochetes reached the satellite lymph nodes and the general circulation had not been definitely determined. Fruffi claimed to have found them one and two weeks after infection. It had been demonstrated by animal experiments that the bone marrow and the testicle contained them before the appearance of the chancre. The *Spirochæta pallida* was essentially a lymph organism but its generalization took place in the early period through the blood stream and from time to time it probably appeared in the blood in the later stages of the disease.

There was now a widespread belief that with the dissemination of the spirochetes in the early period of the disease every tissue was invaded without, however, in all cases producing subjective or objective symptoms. It had been demonstrated that the spirochetes might remain in contact with tissues for long periods of time without exciting microscopic or macroscopic changes. Their knowledge regarding visceral involvement at the time of generalization was rather limited but it was quite probable that lesions analogous to those found in the skin were present. As in these cases the interstitial tissue would more probably be involved if the lesions were superficial, tended to undergo spontaneous regression, and therefore the disturbance of function was slight. Where, however, the intoxication was severe and analogous to that of the eruptive fevers, the parenchymatous portion of the organs was affected and this led to more or less degeneration and destruction with impairment of function. It was believed formerly that the sequence of syphilitic eruptions was dependent upon the parasite and its virulence. The relationship was no longer admitted. In accordance with modern research the various manifestations were interpreted as an expression of the immunity processes which began to develop shortly after the introduction and multiplication of organisms. Clinical and animal experiments had demonstrated that during the first incubation period a change was taking place in the skin and mucous membranes which rendered them resistent to reinoculation under ordinary conditions. This biological change to which the name "anergy" had been applied by Neisser began within a few days of the in-

itial inoculation and was practically complete at the end of the second incubation period or time of the general eruption. If during this period reinoculation was practised it was found that the inoculation period was shorter and that the lesion no longer developed in a typical manner. These phenomena were analogous to those described by von Pirquet under anaphylaxis.

Syphilis of the Arteries and Veins.—Dr. ALEXANDER MCPHEDRAN of Toronto, Ont., presented this paper. He said that few more important advances had been made in modern medicine than the recognition of the morbid changes and the symptoms resulting from syphilitic infection of the walls of the blood vessels. Syphilis as a cause of aneurysm had been known over 200 years, but syphilitic "arteritis" had been known to exist for little more than 50 years. Sir Clifford Allbutt was the first to describe the histological changes (1868) but it was only in recent years that the great importance of the disease had been fully realized, that was, since the *treponema pallidum* was discovered and had come to be recognized as the infecting organism causing the disease. In common with other structures, the whole vascular system might be the seat of infection, but the arteries seemed specially prone to invasion by the infecting organism. Of the arteries, the cerebral were most liable to infection, and next to these the aorta and the coronaries. This might be due in part to the free blood supply to the walls of these vessels, and in part to the sudden increase of blood pressure to which they were so often subjected and by which their resistance to infection might be lessened, as these arteries were surrounded only by loose areolar tissue. It was remarkable that relatively few cases of syphilitic arteritis had had marked symptoms of syphilis or in fact any symptoms. Very many had little treatment. Brain syphilis probably always began as arterial disease in some form. Even gumma began in the periarterial tissue in the pia-arachnoid, although often situated apparently in the brain substance (Mott). Arteritis might begin very soon after the syphilitic infection; it was not rare early in the secondary period. The terms primary, secondary and tertiary had long outlived their usefulness, and should be discarded as they were too often used with reference to the time of occurrence of the lesion rather than to the tissue invaded. In many cases neither primary nor secondary lesions had been observed, the first symptoms being those of disease of the deep structures. Arterial lesions might occur in the first year, in fact some believed the onset as most frequent then, the numbers lessening with each succeeding year.

The reason for the occurrence of arteritis and periarteritis in the relatively few, although the number was large, while the majority of the infected escaped, was difficult to determine. As in other diseases, a variety of causes were operative, such as inherited abiotrophy, or a lowered power of resistance, traumatism, insanitary environment, all varieties of excesses of which alcoholism and venery doubtless had the most influence, and probably most important of all, inadequate treatment after the infection, often no treatment. Age probably had much influence, at least on the distribution of the infection. In children and young people syphilis might infect the peripheral vessels, causing general arteriosclerosis. This was in fact probably the most frequent cause of it, while in those of mature and advanced age the large vessels were most often the seat of disease. Syphilitic arteritis was probably always due to infection of the arterial wall through the vasa vasorum by the tropoma pallidum. The resulting lesions were multiform, varying chiefly with the structure of the arteries, and might be divided into two classes, the large and the small.

1. In the *large* arteries, of which the aorta might be taken as a type, the wall consisted chiefly of elastic and white fibrous tissue. The lesions were usually quite characteristic, consisting in the early stages of gelatinous looking plaques, caused by infiltration and thickening of the intima. These might be confined to narrow areas at the root of the aorta, but might be found in any or all of the larger arteries. Later they became paler or of a bluish tint, and showed fibrous looking depressions of various shapes and sizes, often with linear scars. On section they were always found to be associated with mesarteritis and periarteritis of the corresponding areas, in which there was perivascular infiltration about the vaso vasorum, and fracture and splitting of the elastic tissue. In these infiltrated areas in the media giant cells were found. Later the elastic tissue was quite destroyed and replaced by these gummatous formations. In many cases *Spirochæta pallida* had been found in these areas. There was, therefore, little room for doubt that the primary infection was in the media, spreading later to the intima and adventitia. Similar lesions had been found in the large vessels in cases of congenital syphilis. These changes in the vessel wall weakened its resistance so that it yielded to the blood pressure and an aneurysm formed. In fact, the great majority of aneurysm had this origin, all of them probably occurring before early middle life. The introduction of the Wassermann test afforded good ground for this view. He had only met with one case without evidences of syphilis and this occurred recently in a man of 60. He had been a caretaker of a large building and therefore doubtless subjected to heavy strain.

2. In the *small* vessels, whose walls were composed chiefly of muscular tissue, endarteritis and sclerosis were the morbid changes met with. As in the brain, the heart or the limbs, single vessels or groups of vessels only might be affected or the disease might be widely distributed, involving the vascular system generally. The endarteritis might be nodular, deforming and reducing the lumen of the vessel, or wholly obstructing it at various points. This proliferated tissue showed little tendency to undergo caseation, but as it grew older it usually became denser and converted into cicatricial tissue. In this manner a more or less widespread arteriosclerosis might result. It was probable that many cases of general arteriosclerosis, especially in infants and children, and even in those of mature years, were due to fibrosis following the degenerations caused by the devitalizing effect of syphilitic infection. Broadly viewed, the symptoms arose (1) from the disturbance or arrest of the blood supply to an organ or tissue and (2) from pressure as of an aneurysm or gumma on surrounding structures. To these should be added probably spasm of the heart or aorta, arising from areas of weakness caused by local disease. Painful spasm of a similar character and due to arterial disease occurred in the skeletal muscles in intermittent claudication. Symptoms from occlusion in endarteritis would depend on the suddenness of the onset and the degree of collateral circulation. For example: The Circle of Willis regulated the blood pressure in all of the blood vessels within the cranium. The free communication maintained an equable supply of blood to all the branches even if one section was closed, but the closure must be gradual in order to permit of the anastomosis being sufficient to maintain a good circulation. This was well illustrated by the occlusion of the basilar artery. If sudden, instant coma resulted, followed by death within a few hours, but the artery was not rarely found completely closed at death, without there having been any symptoms enabling a diagnosis to be made. Even very small aneurysms that only pouched during life when under the pressure of the blood stream might cause serious damage. Such an aneurysm might compress one of the coronary arteries and, if occurring suddenly, prove fatal (Winternitz). Endarteritis of cerebral arteries not only led to partial closure of the artery but also to loss of elasticity and, therefore, disturbance of equality of the pressure might occur under varying circumstances, as shown by slight dizziness, a dazed mental state, momentary loss of certain functions, as of power of speech, temporary paresis of any part. Even with healthy arteries, many people with rather low blood pressure had similar disturbances on sudden movements, *e.g.* sitting up suddenly, stooping over quickly, showing how easily a momentary change in the force of circulation might occur in ordinary health.

The Evolution and Treatment of Hyperthyroidism in Its Mild Types.—Dr. HARLOW BROOKS of New York presented this communication in which he said that every physician knew that tachycardia, exophthalmos, goiter and tremor were the cardinal symptoms of hyperthyroidism and when found together they constituted a very definite and unmistakable disease picture. He wished, however, to discuss not the well marked and fully developed cases of exophthalmic goiter, but those usually obscure and incomplete types of hyperthyroidism which in his opinion were more numerous and far more important, especially from the standpoint of medical treatment. Symptomatic discrepancies were naturally especially evident in mild or incompletely developed instances and in the relatively early stages of the disease. Many or most of the characteristic signs and symptoms might be entirely wanting so that an absolute diagnosis was impossible. It was in these very

cases that treatment was most advantageous and successful. The onset was commonly more or less slow. Cases appeared to have a sudden onset as from a nervous shock, a fright or from some traumatic condition. Close analysis of such cases, however, showed almost without exception a long standing predisposition and instead of really being sudden in onset a tendency toward hyperthyroidism had long existed. True exophthalmic goiter rarely developed before the sixteenth year, but they constantly saw children and especially young girls showing definite traits of mild hyperthyroidism before this age, particularly about the period of menstrual establishment. Enlargement of the thyroid gland took place in early girlhood particularly at that time when the menstrual functions were about to appear, when the mammary glands were undergoing rapid development and when at the same time the fancies, the affections, the passions and the "temperament" of the young woman were in rapid process of establishment. Precisely though less striking changes appeared in boys. By no means infrequently the enlargement of the thyroid at this period and the consequent sensations of swelling and neck disturbances which it caused gave rise to the diagnosis of a globus hystericus. One could not consider these signs and symptoms as pathological in type except as to degree, for they knew how dependent the development of the sexual apparatus was upon thyroid activity.

Cretinism and myxedema were of course extreme degrees. Both were characterized by retrogression, or by lack of progression in physical and psychic growth. The cretin was a dwarf of undeveloped mentality. The myxedematous patient became physically defective and mentally incompetent, entirely unable to think in an original manner. The physiological secretion of the thyroid in adolescence indexes mental and physical activity and growth. Charm of personality and the mental and physical differentiation of the sexes occurred very largely under and as a direct result of thyroid secretion. Normal cleverness and responsiveness became exaggerated into precocity and petulence, and active and deft muscle and nerve response became ataxia or tremor, bright and sparkling eyes into an exophthalmos. Normal sex differentiation was transmuted into hysteria, perversions and "nervousness," etc. Many of these characteristics were likely to escape the observation of the physician who did not know what he was looking for and the case might be pronounced one of "nervous heart," "hysteria," "laziness," "perversion" and so on. For some time such cases had been properly classified under the heading of Formes Fruste or of undeveloped exophthalmic goiter, though admittedly many such cases even untreated would never develop true Graves' disease. In Dr. Brooks' experience there were very many instances in which nature was a more wise physician than the surgeon and in his observation where physicians were able to carefully and especially individually study these cases, brilliant results might be confidently expected more definitely without rather than with the assistance of surgery. Many school physicians and intelligent parents were beginning to grasp the fact that the psychic or nervous management of these children was very important. The precocious child was held back from her studies, the neurotically inclined boy was put into the open and given occupations which taxed not his higher but his more primitive resources. He was sent to the farm, to the boy's camp or to the occupational school. Instead of too many books and too much music, the little girl should be given routine duties, taught to cook, to sew and mend, to use her hands instead of her head. She was sent into the open in preference to the classroom. Theaters and parties were to be replaced by tennis and horseback riding and by all manner of other interesting, absorbing, yet primitive, simple and healthful occupations. Such a régime of mental supervision, treatment if one liked, did more to quiet down the heart action, to check the outbursts of temper, or temperament, than all manner of radical surgical procedures. The selection of a proper school was a very weighty matter in these cases. In cases where home conditions were salutary, it seemed better to have the child attend a school which permitted its return each night. Such a course presupposed a home surrounding of quiet and order with parents of even temper and judicial calm. It demanded a school in which the spirit of competition was subordinated and in which, in so far as was possible, an attitude of privilege and pleasure was thrown about instruction. For many children suffering from this tendency to hyperthyroidism, the religious schools with their attitude of trust in Omnipotence with the devotional services, which formed as it were an outlet for the sentimental and passionate side of many natures, were of very definite medical desirability. Such institutions were far less frequent in this country than in Europe and he referred particularly to many Sisters' Schools, especially in France, Belgium, and Southern Germany. The entire absence of flirtatious escapades in such institutions aided very materially to subordinate the growth of the sexual instincts. It was doubtless true, as the psychanalyzers assert, that religious devotion and fervor in not infrequent cases supplanted or typified the sexual. On the other hand, cases existed in which the routine of religious exercises irked and irritated to the point of almost terror.

With a naturally irritable and overacting heart, exercise must be so adjusted that no excessive strain was placed on the circulation. Medical treatment should not be neglected, and while the crux of his paper had been to emphasize the therapeutic necessity of training and of the psychic side of the treatment, ordinary medical methods were by no means to be subordinated. Anemia was a condition associated in these cases in a very large number of instances. Iron must be used in nearly every case. In the average case the old-fashioned tincture of the chloride of iron, Bashams Mixture, or the syrup of the iodide of iron were most useful. In cases associated with chorea, arsenic acted very beneficially. Any treatment in each instance must be of long standing and be sustained and usually until the child had passed to the adult when in case a normal life was possible, complete cure was likely to become firmly established. It was his belief that most cases recovered spontaneously, though they might suffer throughout life from more or less thyroid instability. The important matter, however, appeared to be early recognition and persistent supervision.

AFTERNOON SESSION.

DR. G. REESE SATTERLEE IN THE CHAIR.

Election of Officers.—*Chairman,* Dr. John L. Heffron of Syracuse; *Secretary,* Dr. John M. Swan of Rochester.

Clinical Observations of Mild Cases of Hyperthyroidism.—Dr. JOHN M. SWAN of Rochester read this paper. He said that he was inclined at the present time to look upon hyperthyroidsm as a disease of metabolism characterized by tachycardia and associated, with varying frequency, with exophthalmos, struma, nervousness, tremor and other systemic disturbances. The metabolic disturbance that was responsible for the disease appeared to be connected in some way with iodin chemistry. The disease was chronic and showed acute exacerbations from time to time. The pathologic changes in the thyroid gland might be hyperplastic, colloid degenerative, fibrotic and hypoplastic (Marine and Lenhart). All three stages might be seen in the same gland. The acute exacerbations were usually associated with hyperplastic changes. When the disease became quiescent colloid degeneration had occurred. When the fibrotic and hypoplastic stage appeared the symptoms ordinarily known as hypothyroidism developed. The usual train of events in this disease might be theoretically outlined somewhat as follows: An individual had been sickly during childhood, or if not sickly, had been delicate, perhaps anemic and easily the victim of infectious diseases. Indeed, when the infections developed he was perhaps sicker than others of his acquaintance. At the time of puberty he became nervous, irritable and complained of indefinite disturbances, perhaps of the respiratory system, perhaps of the gastrointestinal tract, possibly of the genitourinary organs. If the case was studied at this time the individual might be found to have an enlarged thyroid gland, rapid pulse and nystagmus, or one of the other eye signs. During these years he was likely to develop a scoliosis. In the third decade, and perhaps in the first half of the third decade, an acute infection like typhoid fever, fright, some disappointment, or severe sorrow would be followed by the development of well marked Graves' disease. If Graves' disease did not develop, the individual continued to become more nervous and apprehensive, perhaps develop some phobia, and gradually passed into a condition of outspoken neurasthenia. Still later on, cardiac hypertrophy developed from the constant overactivity of the cardiac muscle. The increased blood

pressure attendant upon the cardiac hypertrophy started arterial and renal changes, or possibly the direct action of the altered thyroid secretion might produce renal changes, which, by further increase of blood pressure, interfered more and more with the hypertrophied heart and increased the atherosclerosis, so that in the last years of life the patient became a cardiorenal case of classical type, but perhaps without satisfactory antecedent history to account for the development of the disturbances. At any stage of the development of this train of pathological disturbances the condition might become quiescent and apparently be arrested. In women, for instance, they sometimes saw this as an apparent result of marriage, although sometimes marriage and pregnancy were attended with an aggravation of the condition. Again, the arrest of the condition might be followed by retrograde changes which had been repeatedly described under the term of hypothyroidism; increase in weight, increase in the size of the hands and feet, mental sluggishness, loss of hair and arthropathies.

The Heart in Syphilis.—Dr. HARLOW BROOKS of New York read this paper. He said that the condition was now reported with great frequency from all communities of the sick who were observed with sufficient care to permit of the recognition of so obvious a lesion. It had now certainly been shown that invasion of the heart began at least as early as the first appearance of secondary symptoms or signs and that at this period extensive and serious lesions of the circulatory center might even then exist. Many of the older authors who had considered this subject had given the impression that involvement of the heart occurred only as a late manifestation of lues. When one fully recognized that syphilis was a septicemia, any other conclusion would be necessarily illogical, even had it not been now certainly shown that symptoms, signs and even fatal lesions occurred in the heart in the secondary stage of the infection. Carrol and he had thus far reported 25 cases of cardiac involvement in this period of the infection. Though Dr. Brooks was of the opinion that in all probability very many instances of cardiac involvement originated at this time, as a matter of fact most of them were not recognized until late in the tertiary stage. His conclusions throughout had been, however, that close routine examination of cases of secondary syphilis from the internist's standpoint would disclose abundant examples of evident serious heart involvement at this early stage. Fortunately the mortality rate at this period was not high because nearly all instances of secondary lues were at least for a time correctly and more or less vigorously treated. Analysis of the lesions found at post mortem examination in cases of heart involvement showed that disease of the myocardium was the most frequent. The dominant and earliest lesion consisted of a true syphilitic myocarditis which, as first demonstrated by Adler in 1898, originated about the terminal arterioles of the coronary system. As regarded the involvement of the heart valves, their studies had corroborated the general opinion as to the prediction for the aortic segments, though signs of mitral discrepancy commonly appeared first. The great importance of disease of the coronary artery in syphilis could not be too highly emphasized and it should be noted that the probable earliest lesions in the muscle originated as a periarteritis. His studies had shown that the severity of coronary involvement was not so much dependent upon the time or stage of the invasion as on its activity. Age also appeared to be a negligible factor and he had reported advanced cases at the respective ages of 23, 26 and 28 years. As to the occurrence of circulatory symptoms in the late stages of syphilis, of 200 cases analyzed in this respect, 164 entered an internal service making complaints of circulatory discrepancies. In many, perhaps most of the cases, symptoms of heart involvement were not complained of until long after the primary infection and the lesions not infrequently remained fully compensated until approaching old age or an extraneous incident revealed them. After the secondary stage nothing symptomatically characteristic of syphilis was shown by the heart lesion, and the signs and symptoms manifested in each case were respectively those due to the specific anatomical change present whether it was an endocarditis, a myocardial degeneration, cardiac gumma, aneurysm or a small cardiac fibrosis. The association of cardiac symptoms and signs with other stigmata of lues were the only specifically diagnostic features. Analysis of the symptoms presented in their group of over 300 cases had shown, however, the prominence of signs and symptoms indicating muscle discrepancies. Named in their relative order of frequency and taken as a whole, irrespective of the specific anatomical changes presented, the symptoms had been dyspnea, tenderness and pain in the precordium (at times true stenocardia due to dilatation or to coronary disease), disturbances of rhythm, including heart block and insomnia. The question of the diagnosis of heart involvement in syphilis resolved itself into two factors, the diagnosis of the general infection and that of the special cardiac lesion.

Dr. Brooks said he could not speak too highly of the value of the Wassermann reaction for the recognition of lues as a causative factor in cardiac conditions of obscure etiology. They had found it but rarely negative where the cardiac symptoms were of an aggressive character. The treatment resolved itself into that designed to attack the specific and causative infection, to remove in so far as possible its resultant lesions and that designed to benefit the elementary circulatory changes. The treatment of either type must be individualized. Unless the aggressive character of the case demanded the most prompt possible check, Dr. Brooks preferred to introduce treatment by the use of intramuscular injections of the salicylate of mercury. Other forms of mercury medication were also employed. They had never had a serious accident following this method. Subsequently in most cases salvarsan was given three or more times. He had found that the old salvarsan was most efficient and most permanent in its effects. Where an immediate check of the process seemed to be imperative, he had used the prompt intravenous injection of salvarsan, usually with excellent effect. As a result of their experience, he preferred to precede definite cardiac methods of treatment, except as to the customary physical and precautionary measures, by specific methods. He was convinced, for example, that drugs of the digitalis group produced much more definite and permanent effect when given after rather than before or during the early specific treatment. The specific treatment must be persistently prosecuted as in other cases of acute or long standing syphilis. Sporadic specific treatment gave much less decisive or satisfactory results as compared to those instances where the specific treatment was persistently carried out. With regard to prognosis, he believed that in early instances the heart disease might be radically cured, in most cases by specific measures alone, and even in active luetic endocarditis or myocarditis.

Metabolic Studies in Diabetes.—Dr. FREDERICK M. ALLEN of New York City said that partial pancreatectomy in animals gave a rather close imitation of human diabetes; there might be seen a similar progress from mild to severe forms, a similar aggravation by unsuitable diet, and a similar improvement by properly restricted diet. Animals in a suitable diabetic condition could be made sugar free by fasting. After one or two days of sugar freedom it was possible to begin feeding cautiously and to keep the animal permanently sugar free with no downward progress on a certain diet, whereas an increase of this diet would send the animal into diabetes with a progressive downward course. Sometimes the diet must be so low that the animals were kept very thin, and only in this thin condition could they be kept free from diabetes. Restriction of carbohydrate and protein and the use of occasional fast days were part of the regular treatment for diabetes. The present paper dealt with metabolism rather than treatment, and the following observations concerning diabetic metabolism might be mentioned. Broadly speaking, glycosuria could be stopped in any case of human diabetes by sufficient fasting. The patients ordinarily bore the fast excellently, acidosis was quickly and markedly diminished, generally down to small traces. A more difficult feature of the program was to feed subsequently so as to keep the patient free from glycosuria and acidosis, but this had so far been accomplished in even the most severe cases; this was accomplished even if it be necessary to diminish the patient's weight considerably by fasting and low diet. Reduction of weight by this means appeared to act favorably upon the diabetic condition. Subsequently, it was ordinarily possible gradually to increase the diet and the weight. This recuperative power varied with the different patients. Instead of the unlimited fat heretofore allowed diabetics, the fat was carefully restricted in all severe cases under this treatment. Their patients took no alkali unless for a very brief period at the outset. They showed no specific craving for carbohydrate. They ordinarily followed their diet and remained free from symptoms after discharge so far as observations yet ex-

tended. Considerable time would be necessary to establish whether patients had an inherent downward tendency, or whether diabetes was merely the weakness of a metabolic function which remained stationary or even improved when the overstrain of this function was relieved.

Some Practical Questions on Metabolism.—Drs. JOHN L. BUTSCH and CHARLES G. STOCKTON of Buffalo presented this communication in which they first made a plea for the closer study of these cases and the reason why cases should receive more time and consideration. They dealt with some of the problems involved in the treatment of disturbed metabolism, such as the constantly changing degree of tolerance in rather a small range. They spoke of the kind of carbohydrates to be given, how it was given, the effect of the proteids and the effect of the total amount of food for the day. Two cases illustrating their point were reviewed somewhat in detail. They told of their method of study, their method of handling a case which presented itself for study, the blood examination, the examination of the stools, of the urine, etc. They discussed the dieting of the patient and told what they could accomplish by close study of the dietary in the present state of their knowledge.

Thursday, April 29—Third Day.

This was a joint meeting with the Section on Surgery. (See report of Section on Surgery, page 794.)

State Medical Licensing Boards.

STATE BOARD EXAMINATION.
QUESTIONS.

STATE BOARD OF MEDICAL EXAMINERS OF NEW JERSEY.
October, 1914.

(*Continued from page* 714.)

PATHOLOGY.

1. What is the difference between hypertrophy and enlargement?
2. Give theory of diabetes mellitus.
3. Describe gout; give theory.

BACTERIOLOGY.

1. Name the pathogenic spirilla and diseases caused by them.
2. Describe mycetoma.
3. Name the pathogenic protozoa and give life history of the dysentery ameba.

HYGIENE.

1. What is a water shed?
2. How can it be properly safeguarded, and why?
3. Name the water-borne diseases.
4. What is the best general method of purifying drinking water?
5. How may ground water injuriously affect the public health?

MEDICAL JURISPRUDENCE.

1. What is the difference between molecular and somatic death?
2. What are the signs of, and how can you determine between, real and apparent death?
3. How would you conduct an autopsy?
4. Name most of the causes of violent death, and tell how you would differentiate them.
5. What is the object of a coroner's inquest?

PRACTICE OF MEDICINE.

1. Differentiate rachitis and scurvy.
2. Describe the several kinds of arterial pulse.
3. Differentiate catalepsy, epilepsy, and hysteria.
4. What diseases may cause occlusion of the common bile-duct?
5. Describe the varieties of stomatitis, giving the causes of each.
6. Describe vocal fremitus and name the conditions causing its increase or decrease.
7. Describe the urinary casts; where formed and the disease each indicates.
8. Describe the eruption *only*, in its different stages, of measles, scarlet fever, and smallpox.
9. Describe the pathological pulmonary sounds heard on auscultation of the lungs and name the conditions causing them.
10. Describe the normal heart sounds and state the points on the chest where each is heard with the greatest distinctness.

ANSWERS.

PATHOLOGY.

1. In *hypertrophy*, all of the tissues or constituents of an organ are increased in size or weight or number.

In *enlargement*, only one tissue of the organ is increased.

2. *Theory of diabetes:* "The theoretic interpretation of diabetes varies with the view which may happen to be held of the glycogenic function of the liver. Normally about 0.1 per cent. of sugar is present in the blood, and a minute trace, which the clinical tests cannot detect, in the urine. When the amount in the blood is more than 0.2 per cent. an appreciable glycosuria occurs, and even in health a temporary glycosuria may be produced by an ingestion of sugar beyond the physiological limit. The appearance of sugar in the urine is thus due to an excess of sugar in the blood. The usual view of the glycogenic function is that the liver converts the carbohydrates brought to it from the intestines into glycogen, which it stores up as a reserve, and gradually reconverts into sugar and delivers *via* the blood to the tissues according to their needs. On this view the excess of sugar in the blood is due either to excessive production of sugar in the liver, or to diminished oxidation by the tissues. On the other hand, Pavy holds that part of the ingested carbohydrates is converted by the intestinal villi into fat, and another part is synthetically built up into proteids, in which forms it reaches the blood, and that only a portion reaches the liver, where it is stored up as glycogen, and prevented from entering the general circulation except in synthetic combination with proteid bodies. A temporary glycosuria would therefore be due to a defect in the sugar-transforming mechanism, and diabetes to its arrest, permitting the passage of unaltered glucose. In mild forms of the disease, a diet free from carbohydrates stops the glycosuria, the excess of sugar being thus derived from the carbohydrates of the food; but in severer cases, glycosuria persists though carbohydrates are withheld, and sometimes even though no food is taken. In these instances, sugar is formed by disintegration of the proteids of the food, and in the gravest cases by disintegration of the body proteids. It remains to explain why the excess of sugar is not utilized by the tissues, is not, that is, oxidized in the ordinary manner by the muscles. It has been conjectured that it may require previous elaboration in other organs, and as the pancreas is in many instances diseased attention has been directed to that gland. The recent researches of the younger Cohnheim are suggestive in this regard. He finds that neither pancreatic juice nor muscle juice has singly any action upon sugar, but that when the two are combined the sugar is rapidly broken up. He holds, therefore, that the proenzyme produced in the muscles is only activated by a glycolytic substance contained in the pancreatic juice, and probably derived from the internal secretion of the islands of Langerhans. Extensive disease of the pancreas would destroy this substance, and render the sugar unavailable for combustion in the muscles. It must be added that, in some cases, no disease of the pancreas or liver has been found. In some of these there has been disease in the region of the "diabetic puncture" (floor of the fourth ventricle)."—(Wheeler and Jack's *Handbook of Medicine.*)

3. "*Gout* is a condition characterized by attacks of acute arthritis and other constitutional symptoms, clinically, by the excess of uric acid in the blood, and anatomically, by the deposit of sodium biurate in the cartilages and elsewhere. It must not be imagined that this excess of uric acid in the blood is the cause of the disease, for uric acid in excess exists in the blood in a number of different states without gout being present. The urates are inert bodies, and the most that can be said is that they are an indicator; that is, the faulty metabolism which produces them produces also substances that are toxic. These substances we do not know with any exactness. . . . It is necessary to know, more fully than we do, the toxic effects of the purin bases, for they are toxic, and it is perhaps the purin bases that are responsible for gout. Gout, therefore, is probably the outcome of insufficient oxidation, whereby the precursors of the uric acid, and similar bodies, are not fully oxidized, and by their accumula-

tion and their toxicity, set up morbid changes; and the uric acid formed is in its turn imperfectly oxidized, and accumulates; this diminished oxidation is due to a constitutional deficiency of oxidases, inherited or acquired."—(Adami and McCrae's *Textbook of Pathology.*)

BACTERIOLOGY.

1. PATHOGENIC SPIRILLA. *Spirillum choleræ* found in Asiatic cholera; *Spirochæta recurrentis*, in relapsing fever; another variety of the same, in Congo tick fever; *Spirochæta pallida*, in syphilis; *Spirochæta refringens*, in syphilis; *Spirochæta fusiformis*, in Vincent's angina.

2. "*Mycetoma*, or Madura foot, is a localized chronic inflammation, almost painless, and usually involving the foot, the hand, or some exposed portion of the body. The disease involves the tissues by direct extension, attacking the bones as well as the soft tissues. It usually remains localized to one extremity. It is due to the *Streptothrix maduræ*. The black variety of Madura foot is due to a different organism, the threads of which are 3 to 8μ in thickness. This organism seems to be an aspergillus, and has been named *Madurella mycetori*." —(MacNeal's *Pathogenic Microorganisms.*)

3. *Pathogenic protozoa:* The ameba of dysentery (*entamœba histolytica*), *Trypanosoma lewisi*, *Trypanosoma evansi*, *Trypanosoma brucei*, *Trypanosoma gambiense*, a trypanosoma probably causing kala-azar, *Plasmodium vivax*, *Plasmodium malariæ*, *Plasmodium falciparum*, *Piroplasma* (various species pathogenic for animals), and *Balantidium coli.*

"The ameba is a rounded cell with a clear outer ectoplasm, and a granular endoplasm. It has a rounded or oval excentric nucleus, and measures from 10 to 15μ in diameter. On the warm stage it shows active ameboid movement. In the resting stage it forms a cyst or cysts, and in this state resists drying for a long time. The organisms are found chiefly in the large intestine, especially in the rectum and flexures, but they also occur in the ileum and stomach, and in the liver. They have the power of penetrating the tissues."—(Wheeler and Jack's *Handbook of Medicine.*)

HYGIENE.

1. A *watershed* is the region from which a water supply is derived.

2. It can be properly safeguarded by preventing the discharge of sewage or waste into the source of water supply; also by purification.

3. The *water borne diseases* are: Typhoid, cholera, gastric and intestinal irritation, parasites, and diseases, diarrhea, dysentery, and (according to some) goiter.

4. Drinking water may be purified by distillation, or by filtration, and boiling.

5. Ground water may become polluted in its course through the soil, or after it has passed through the surface soil.

MEDICAL JURISPRUDENCE.

1. By *molecular death* is "understood the incessant disintegration of tissue which is going on in the body during the active processes of life; the waste of material thus produced being compensated by the reparation. In youth, the supply is in excess of the waste, and growth is the result; in advanced age, the reverse is the case. *Somatic death* is the cessation of all the vital functions of the body, or the death of the whole body. The latter is the popular idea of death, and the time when it takes place is generally recognizable. The precise period when universal *molecular* death occurs cannot be accurately determined. No doubt, molecular life may continue some time after somatic death, as is evidenced by postmortem temperature and muscular irritability, by the postmortem beating of the heart, and by certain acts of nutrition and secretion." —(Reese's *Medical Jurisprudence.*)

2. *Signs of death:* Complete and continuous cessation of circulation and respiration; loss of body heat; pallor; rigor mortis; cadaveric lividity; putrefaction; adipocere formation; and, occasionally, mummification. The presence of some of these signs of death marks the difference between real and apparent death.

3. For a complete answer to this question the reader must consult one of the standard works on pathology or medical jurisprudence.

4. *Causes of violent death:* Wounds, burns, and scalds, suffocation, hanging, strangulation, electricity, drowning, excessive heat or cold, starvation, and poisoning.

5. The *object of a coroner's inquest* is to discover the cause of death when the latter is unknown, or inexplicably sudden.

PRACTICE OF MEDICINE.

1. In *scurvy*, the cardinal symptom is the extravasation of blood beneath the periosteum, with resulting thickening and tenderness of the shaft of the bone. The pain in the legs, their position, and the spongy and bleeding gums are symptoms of nearly equal importance. The disease may be suspected in any child who has difficulty or pain in moving the legs, or in whom paralysis is suspected.

In *rachitis*, although the early stages may be indistinguishable, there soon develops the rachitic rosary and the enlargement of the ends of the long bones; pain is, as a rule, absent; and ecchymoses, petechiæ, and spongy gums are not observed. Both may coexist. —(Butler's *Diagnostics of Internal Medicine.*)

2. KINDS OF ARTERIAL PULSE. The normal pulse; the pulse of increased frequency, or tachycardia; the pulse of decreased frequency, or bradycardia; the intermittent or irregular pulse; the high tension pulse; the pulse with a wave of great volume; the slow, or tardy pulse; the dicrotic pulse.

3. *Catalepsy* is a condition characterized by muscular rigidity of the limbs; the affected limb will stay for a long time in the position in which it is placed; the patient is insensible.

EPILEPSY.	HYSTERIA.
1. No apparent cause.	1. Cause, emotional.
2. Sudden and rapid onset.	2. Onset gradual, usually after some mental excitement.
3. Aura generally present.	3. Globus hystericus or palpitation.
4. Consciousness lost.	4. Consciousness generally preserved.
5. Pupils generally dilated.	5. Pupils normal.
6. Tongue often bitten.	6. Tongue never bitten.
7. Patient very liable to hurt himself.	7. Patient not liable to hurt himself; may injure others.
8. May be involuntary bladder and bowel discharges.	8. Never.
9. Of short duration.	9. Duration longer.

4. The *common bile duct may be occluded* by: Gallstones; ulceration; parasites; foreign bodies; pressure from outside by tumor of pylorus or pancreas, abdominal tumors, aneurysm, or enlarged glands; cicatricial contraction following duodenal ulcer or syphilis of the liver.

5. VARIETIES OF STOMATITIS, WITH CAUSES. *Catarrhal stomatitis*, due to dentition or gastrointestinal disturbances in children, irritating or too hot food, and the acute infectious diseases. *Aphthous or follicular stomatitis;* canker, sore mouth is most common in infants and young children, either as an idiopathic affection or as a result of indigestion or a febrile attack; and occurs in adults when the general health is impaired. *Ulcerative or fetid stomatitis;* putrid sore mouth occurs most commonly in children during the first dentition, and may be epidemic, even in adults, in asylums, jails, and camps, where the hygienic conditions are poor. *Parasitic or mycotic stomatitis;* this affection (thrush, soor, muguet) is dependent upon the *Saccharomyces* (or *Oidium*) *albicans.* It occurs mainly in bottle-fed infants. Predisposing conditions are uncleanliness of the mouth and of feeding utensils, and cachectic or diseased states in general, in adults as well as children. *Gangrenous stomatitis;* cancrum oris or noma is a rare disease, affecting children of from 2 to 5 years of age, and occurring usually during convalescence from the acute fevers. More than fifty per cent. of the cases follow measles; less frequently it occurs after typhoid fever, scarlet fever, variola, and whooping-cough. Debilitated and cachectic states also predispose. The exciting cause is probably a yet unknown microorganism. *Mercurial stomatitis;* due to personal idiosyncrasies this may follow the use of repeated minute doses of a mercurial; or it may be an occupation poisoning. *Subvarieties of stomatitis;* in the newborn there may be small ulcers of the hard palate, symmetrically placed on either side of the median line, which may involve the bone (Parrot). Similar ulcers on the hard palate may be caused in

marasmic children by the irritation of a rubber nipple (Bednar). Jacobi has described a chronic recurring herpetic eruption of the buccal cavity in neurotic persons, sometimes coexisting with erythema multiforme." —(Butler's *Diagnostics of Internal Medicine.*)

6. *Vocal fremitus* is the vibration of the chest communicated to the hands of the physician while the patient is speaking. It is *increased* in lobar pneumonia, tuberculosis of the lungs, and bronchopneumonia; it is *decreased* in pleural effusions, emphysema, collapse of the lung, tumors of the lung, and pulmonary edema.

7. *Urinary casts* are moulds of the uriniferous tubules of the kidney. *Epithelial tube casts* are found in desquamative nephritis. *Blood casts* are found in acute renal hyperemia, acute nephritis, hemorrhagic infarction, and renal hematuria. *Pus casts* are found in suppurative nephritis and pyelitis. *Bacterial casts* are found in pyelonephritis and suppurative nephritis. *Granular casts* are found in chronic degenerative processes of the kidneys. *Fatty casts* are found in subacute or chronic nephritis with fatty degeneration, especially large white kidney. *Hyaline casts* are found in all inflammations, acute or chronic, of the renal tubules. *Waxy casts* are found in subacute or chronic nephritis. —(From Butler's *Diagnostics of Internal Medicine.*)

8. *Smallpox:* The eruption usually appears first on the forehead and wrists, and on the third or fourth day; it is first macular, then papular, then vesicular, and finally pustular; it does not appear in successive crops; the spots are multilocular, and do not collapse on being punctured; the papule is hard and shotty, and does not disappear on stretching the skin.

Scarlet fever: Character of eruption, a scarlet punctate rash, beginning on neck and chest, then covering face and body; desquamation is scaly or in flakes. As compared with smallpox and measles, the eruption is brighter, is on a red background, punctiform, and is more uniform; the temperature is higher, the pulse quicker; the tongue is of the "strawberry" type, the lymphatics in the neck may be swollen, and there is sore throat; Koplik's spots are absent. *Measles:* Character of eruption, small, dark red papules with crescentic borders, beginning on face and rapidly spreading over the entire body; desquamation is branny. As compared with scarlet fever, the eruption is darker, less uniform, more shotty; Koplik's spots are present.

9. *Pathological sounds heard on auscultation of the lungs: "Bronchial breathing* occurs in *lobar pneumonia*, phthisis, compensatory emphysema, tumor, syphilis, and infarct. Both inspiration and expiration are harsh and have a high-pitched (tubular) character. *Cavernous breathing* is low-pitched and blowing in character and is heard over cavities. *Amphoric breathing* is similar to the sound produced by blowing gently over the mouth of an empty jar. It is present in phthisical cavities, pneumothorax with patulous opening, and localized consolidation near a large bronchus. Adventitious sounds include râles, metallic tinkling, and pleuritic friction sound. Râles may be dry or moist: *Dry râles* occur in bronchitis and asthma, and may be low-pitched snoring sounds (sonorous râles) or high-pitched whistling sounds (sibilant râles). *Moist râles* are produced by the passage of the air through liquid, and may be crepitant, subcrepitant, or gurgling in character. *Crepitant râles* are extremely fine and occur at the end of inspiration; they are heard in the first stage of pneumonia and in engorgement and edema of the lungs. *Subcrepitant râles* are comparatively few in number, and are heard during inspiration and expiration, in capillary bronchitis, pulmonary edema, hypostatic pulmonary congestion, and incipient phthisis. *Gurgling râles* may be large or small, and are heard during inspiration and expiration in phthisical cavities, bronchial hemorrhage, in the stage of secretion in bronchitis, and over the trachea. *Metallic tinkling* is a bell-like sound heard in pneumothorax and phthisical cavities, and is caused by the dropping of a liquid through the space inclosed in tense walls. The *succussion splash* is produced in pneumothorax when the patient is suddenly shaken. *Pleuritic friction sounds* are heard during inspiration and expiration, and do not pass away after coughing. They are pathognomonic of pleurisy."—(*Cyclopedia of Medicine and Surgery.*)

10. The first, or systolic, sound is dull and somewhat prolonged; the second, or diastolic, is sharper and shorter. The sounds may be expressed by the syllables *lubb—dup.* The first is heard best in the fifth left intercostal space; the second over the second right costal cartilage.

(To be concluded.)

Therapeutic Hints.

Allylmorphine.—A. Mayor and B. Wiki state that this is a new derivative of morphine obtained by the substitution of the allyl radicle for a phenol group in the morphine molecule. The sulphate of allylmorphine has an action notably different from that of morphine. It produces somnolence but not profound sleep. It has a local analgesic action similar to that of morphine. It does not slow respiration and lowers blood pressure. Moderate doses are well borne.—*Revue Médicale de la Suisse Romande.*

Treatment of Intestinal Hemorrhages in Typhoid Fever.—A. Robin details this treatment as follows: Absolute rest; the application of ice to the abdomen; the avoidance of stimulation, and the alternate administration every hour of ergotin in conjunction with gallic acid, and calcium chloride, according to the following formulæ:

℞ Ergotin, 4 grams.
Gallic acid, 0.5 gram.
Syrup of turpentine (Fr. Phar.), 30 grams.
Distilled water, 120 grams.

℞ Calcium chloride, 4 grams.
Syrup of opium (Fr. Phar.), 30 grams.
Distilled water, 120 grams.

The above are given alternately every hour in tablespoonful doses.—*Journal de Médecine et de Chirurgie.*

Treatment of Bedsores.—A. Robin recommends the use of the following ointment after the parts have been washed with Labarraque's solution:

℞ Precipitated sulphur.
Camphor.
Pure glycerin, āā 30 grams.
—*Journal de Médecine et de Chirurgie.*

Pyocyanase in the Treatment of Diphtheria.—A Montefusco records good results obtained by means of insufflations of the throat with pyocyanase, a mixture of enzymes obtained from cultures of the *Bacillus pyocyaneus.* This treatment is used in conjunction with the injection of antitoxin.—*Giornale Internazionale delle Scienze Mediche.*

Treatment of Occupation Rhinitis.—D. Braden Kyle details this as follows: The cause should be removed. As a preventive the nostrils should be protected by moistened cotton or woolen plugs. When ulceration takes place the treatment consists in cleansing, drying, and the application of liquid astringents, as 3 per cent. chloride of zinc. Before ulceration alkaline cleansing solutions should be used, as:

℞ Phenol.
Sodium biborate, āā 10 grams.
Glycerin, 30 grams.
Distilled water, 50 grams.

This should be followed by

℞ Oil of cassia.
Sandalwood oil, āā 5 drops.
Liquid paraffin, 1 ounce.

Or compound tincture of benzoin, with an equal part of boroglyceride, 50 per cent., for its sedative action.—"Diseases of the Nose and Throat."

Treatment of Vomiting in Infants.—A. B. Marfan is accredited with the following formula:

℞ Tincture of belladonna, 10 drops.
Sodium bromide, 1 gram.
Sodium bicarbonate, 1.5 grams.
Distilled water, 60 grams.
Simple syrup, 30 grams.

M. Sig.: Four to six teaspoonfuls per day.—*Journal de Médecine et de Chirurgie.*

THE PROGNOSTIC SIGNIFICANCE OF CHANGES IN THE RETINAL VESSELS.*

BY ARNOLD KNAPP, M.D.,

NEW YORK

PROFESSOR OF OPHTHALMOLOGY, COLUMBIA UNIVERSITY; EXECUTIVE SURGEON, HERMAN KNAPP MEMORIAL EYE HOSPITAL.

THE importance of ophthalmoscopic changes in the retinal blood vessels for the interpretation of general vascular disease has been admitted for a long time. More exact study of these ophthalmoscopic changes in recent years permits us now to formulate the various changes which are observed in the retinal vessels and to state definitely their prognostic significance.

It can be stated both on clinical and on pathological evidence that the presence of sclerotic changes in the retinal vessels pre-supposes with certainty a similar state in the cerebral arteries, but not the reverse (Hertel[1]); in a number of cases of pronounced vascular disease in the brain the ophthalmoscopic condition was normal. The retinal arteries are furthermore end arteries, just as are the cerebral blood vessels which supply the basal ganglia, and are equally exposed to increased blood pressure in the internal carotid artery.

Occurrence.—In general arteriosclerosis changes in the retinal vessels of moderate degree are frequently present, and can be recognized with the ophthalmoscope. Raehlmann,[2] to whom we owe the first careful examination of this subject, found among 210 cases, in nearly one-half, changes in the retinal vessels. Similar results were found by Friedenwald,[3] Lurje,[4] and Hertel. In general, changes in the retinal vessels occur in those cases of general arteriosclerosis in which the large cerebral arteries are particularly involved. Leber[5] believes that there is a direct dependence of the disease of the ocular vessels to that of the mother vessels at the base of the brain.

Arteriosclerotic changes may affect either the arteries or the veins or both, and in a characteristic manner the involvement may be restricted to quite limited vascular areas in the retina, such as the central vessels or one of their branches. In some cases of retinal vascular changes no clinical evidences of general sclerosis can be found. These cases, if carefully watched, will show sooner or later general symptoms.

A case in point is that of a young man who was first seen in 1911, when he was sixteen years old. The right retina presented a number of whitish areas which looked like old hemorrhages. Some of the retinal blood vessels were slightly tortuous. A physical examination by the family physician revealed no general abnormality. Two years later, in 1913, the vision in the right eye became blurred and a number of fresh hemorrhages appeared in the retina. The small arteries in this region were distinctly tortuous. The other eye ground was perfectly normal. The general examination showed the urine to be normal, heart somewhat enlarged, blood pressure 180. This was supposed to be secondary to an obscure intestinal process. Under appropriate general treatment the pressure was reduced to 125. The circulation in the retina improved and no further hemorrhages occurred. In the spring of 1914 there were some additional hemorrhages in the retina. The blood pressure was 130, the urine normal. In the fall of that year there was no particular change in the ophthalmoscopic condition in the right eye. In the left eye there was a hemorrhage below the disc, some pigmentary disturbance in the macula, with distinct vascular changes. The urine showed a trace of albumen. The blood pressure was 140. Latent interstitial nephritis is now suspected.

Physical Signs.—The arteriosclerotic changes may be only microscopic. Hertel found microscopic changes in the retinal vessels of patients with pronounced general arteriosclerosis where no ophthalmoscopic disturbance was found present in the eyes. These arteriosclerotic changes were variable in their distribution and circumscribed. Slight changes can, therefore, not be recognized with the ophthalmoscope. It must, furthermore, be remembered that arteriosclerotic changes do not cause functional disturbance in the retina until the process has progressed to vessel-closure, hemorrhages, or exudates.

In the early stages of retinal arteriosclerosis, according to Thoma,[6] there are increased tortuousness of the arteries, distinct presence of true arterial pulse and a progressive peripheric venous pulse. Raehlmann and Gunn have drawn attention particularly to the variation of caliber in the blood column. These arteries, which are generally narrow, show circumscribed contractions of the lumen with intervening dilated areas, small ectasias, or the beginnings of miliary aneurysms (Leber). In the veins between the constricted areas there are varicose dilatations.

Gunn,[7] in 1892, drew attention to a peculiar shining appearance which the arteries present, suggestive of "silver wire." The light reflex is unusually narrow and bright, not only near the disc, but in branches of the second and third order, which gives the impression of unusual fullness and rounding. The transparency of the vessel wall is diminished, and where the arteries pass over a vein the latter cannot be seen through. Leber agrees with Gunn that a narrowing of the reflex streak and the greater rounding of the artery indicate increase of blood pressure. Gunn furthermore has pointed out the indentation which a sclerosed artery exerts on an underlying vein, and which frequently leads to a peripheric dilatation of the vein. A similar observation was made by Raehlmann, who believes that this pressure causes a circumscribed sclerosis of the venous wall.

de Schweinitz[8] speaks of the following signs as

*Read at Meeting of the Practitioners' Society, March 5, 1914.

being suggestive of retinal arteriosclerosis, "and which must not be disregarded if they are associated with other symptoms of arterial disease. Three signs may be seen early: (*a*) A markedly corkscrew appearance of certain arterial twigs, either of those which skirt the macula, or, more significantly, of one or more small branches which arise from the larger vessels of the main distribution which themselves are apparently normal."

(*b*) "A flattening of a vein where it is in contact with an artery, and at this spot it has somewhat the appearance that a strap would have if laid across a solid tube, provided the vein passes over the artery. If the artery passes over the vein, the appearance is analogous to that which would be produced if the strap were placed across the lower surface of the tube. The vein is only slightly compressed at this stage, but is not yet indented sufficiently to produce an ampulliform dilatation of the vein beyond the point of crossing."

(*c*) "The nerve-head has an appearance often loosely described as 'congested.'"

The diagnosis of congestion of the nerve head should be made with great caution, as there are such wide physiological variations of congestion compatible with a healthy optic nerve. The later ophthalmoscopic signs are changes in the vessel wall by which they become thickened, opaque, and are gradually transformed into white lines which sheath the narrow or obliterated blood current, the lumen becomes narrowed and occluded. Similar changes occur in the veins, though the veins are more tortuous than the arteries in the later stages. Other changes are hemorrhages, edema, and exudates.

Uhthoff believes that these so-called first ophthalmoscopic signs of retinal arteriosclerosis, consisting of slight tortuousness, slight variation in caliber, and a somewhat accentuated reflex streak, are to be interpreted with caution in considering their prognostic bearing on the state of the cerebral vessels, as these changes can occur in the healthy and be physiological. For the certain diagnosis of arteriosclerosis of the retinal arteries the vessel walls must be outlined with white lines (vascular sheathing), and distinctly thickened, the lumen must be narrowed up to the point of ischemia and complete obliteration; in the earlier stages the diagnosis can only be made when arteriosclerotic changes have led to arterial occlusion through thrombosis, as in the picture of closing of the central artery. This represents the most conservative standpoint in the interpretation of the retinal arteriovascular changes. We must, therefore, agree with de Schweinitz in regarding the early signs as suggestive and of importance if associated with other symptoms of arteriosclerosis.

Prognostic Significance.—The important question, how frequently do cerebral complications ensue after the definite ophthalmoscopic diagnosis of arteriosclerotic changes has been made, can only be answered by the systematic clinical following-up of a sufficiently large series of cases. This has been done by Geis in an unusually painstaking and instructive study of a large series of cases occurring in the practice of Uhthoff, by whom all ophthalmoscopic examinations had been made. The following is largely based upon Geis's[8] results:

Distinct arteriosclerotic changes in the retinal vessels indicate the existence of similar changes in the cerebral vessels. The subsequent history of 17 cases of distinct retinal arteriosclerosis were investigated by Geis, and death resulted from apoplexy in all 17 not later than four years.

Cases with the ophthalmoscopic picture of sudden closure of the central retinal artery or of a branch are to be regarded as examples of arteriosclerotic retinal disease when they occur in patients over 40 years of age with no evidence of any other cause or of a cardiac lesion. In these cases the ophthalmoscopic picture has the same prognostic significance as in the case of the visible arteriosclerotic retinal changes, though the apoplectic attack may occur somewhat later. Closure of the central retinal artery in young people up to 39 has no prognostic unfavorable significance.

Vascular changes in the retina, due to syphilis, have not the same serious general prognostic importance as the corresponding arteriosclerotic changes.

As changes in the veins (*venous thrombosis*) occur much more readily than in the artery, Geis's statistics show that in 50 per cent. venous thrombosis is a purely local change, though in 40 to 50 per cent. it was the precursor of cerebral vessel sclerosis. Really definite and serious prognostic significance is only given in those cases where in addition to the lesion in the vein the other retinal vessels showed sclerotic changes.

Retinal hemorrhages, if they are not due to local diseases or to abnormal blood conditions (anemias, etc.), occur when the vessel walls are brittle, especially with the addition of increased blood pressure as in arteriosclerosis. These vessel changes need not be recognizable with the ophthalmoscope. They have the same serious prognostic significance that arteriosclerotic changes in the retinal vessels possess, though in Geis's cases the cerebral hemorrhages did not occur for a number of years. A distinction must be made in isolated hemorrhages occurring in the macular region. These seem to be due to local changes and have not the same serious general significance. This also holds good for the retinal hemorrhages occurring in syphilis. It is very important to realize the necessity of estimating the blood pressure in the presence of retinal hemorrhages. Its increase is a serious sign.

In general, vascular changes in *albuminuric retinitis* are not pronounced on ophthalmoscopic examination. Aside from the usual picture of albuminuric retinitis, we find isolated retinal hemorrhages occurring in nephritis where there are signs of increased blood pressure, and which are probably due to arteriosclerosis. In this condition cerebral apoplexies are to be expected and in the cases which Geis was able to follow they always occurred. At the same time, death resulted at a later stage than is usual in albuminuric retinitis. Thrombosis of the veins occurring in cases with albumin in the urine should be differentiated from cases of albuminuric retinitis and isolated retinal hemorrhages occurring in nephritis, as they do not permit of any general prognostic deductions.

The conditions in *diabetic retinitis* are similar. Aside from the typical diabetic retinitis, we find hemorrhages which must be due to pathological changes in the vessel walls. In these isolated retinal hemorrhages in diabetics the blood pressure is increased in a large number of cases. A definite prognosis in diabetic retinitis can only be given in those cases of isolated hemorrhages associated with arteriosclerotic vascular changes which are to be regarded as precursors of more serious cerebral mischief. In the usual retinitis of diabetic patients,

just as in albuminuric retinitis, apoplexies occurred in only 1/3 to 1/2 of the cases.

Vitreous hemorrhages have not any definite prognostic significance, unless they are associated with distinct ophthalmoscopic signs of arteriosclerotic changes in the vessels. This is readily explained by the number of causes which may produce hemorrhages into the vitreous.

Finally, as to the significance of *subconjunctival hemorrhages*. They occur, as is well known, in all ages and after a great variety of causes and cannot be regarded in any way as forerunners of cerebral hemorrhages.

A very remarkable clinical feature are attacks of *obscurations* which especially patients with vascular disease of the retinal arteries are subject to.[11] They are important as they may be the forerunners of a permanent loss of sight and frequently precede partial or complete blindness. The cause for these obscurations has not been determined. It is perhaps best explained by the acceptance of spasm affecting the vessel, for patients with recurring obscurations have been examined during an attack and the blood vessels were found contracted and obliterated. The spasm is frequently relieved in a very short time and the function restored. It is evident that vascular spasm has a different prognosis, as it affects normal and pathological bloodvessels, and Osler mentions the direct incentive to spasm which pathological vessel changes offer. Russell[11] has suggested the term "intermittent closing" as indicating this vessel action. There are a number of examples of "closing" dependent upon vasomotor phenomena, such as the contraction of the retinal artery, which have been observed in epilepsy, malaria, whooping cough, and migraine. A study of the anatomical changes in retinal arteriosclerosis shows that the slightest change in the blood pressure or the slightest contraction of the vessel will cause an obliteration of the blood column. If this occurs for a length of time which would not be of account in a healthy vessel, in a pathological one it will be sufficient to cause a permanent functional atrophy of the retina. Intermittent closing of healthy retinal arteries may occur without any lasting effect on vision. In diseased retinal vessels this phenomenon is of grave significance.

Conclusions.—1. Distinct arteriosclerotic changes in the retinal vessels indicate a similar state in the cerebral vessels, but not the reverse.

2. Slight changes are suggestive and of importance if associated with other symptoms of arteriosclerosis.

3. "Silver wire" retinal arteries and retinal hemorrhages, if no disturbance of the blood constituents is present, are each indicative of raised blood pressure.

4. In nephritis and diabetes there are changes in the retina due to arteriosclerosis which are independent of and give a different prognosis from the usual albuminuric and diabetic retinitis.

5. Syphilitic disease of the retinal vessels has no general prognostic significance; thrombosis of the central retinal vein is in more than one-half of the cases purely a local lesion.

6. Temporary obscurations of vision in patients with arteriosclerotic changes of the retinal vessels are of grave significance for sight.

STUDIES OF ATYPICAL CHILDREN.

FROM THE DEPARTMENT OF UNGRADED CLASSES IN THE PUBLIC SCHOOLS OF NEW YORK CITY.*

By WILLIAM B. NOYES M.A. M.D.,

NEW YORK.

ATTENDING NEUROLOGIST TO COLUMBUS HOSPITAL; NEUROLOGIST TO THE DEMILT DISPENSARY; CONSULTING NEUROLOGIST TO THE MOUNTAINSIDE HOSPITAL, MONTCLAIR, NEW JERSEY.

A VILLAGE in Southern New Jersey was much stirred up three weeks ago by a religious revival under the direction of speakers who are associated with "Billy" Sunday. A number of the town drunkards were converted and several individuals known to be feeble-minded of a type that is rather common in that part of the State. A physician who was personally much interested in the movement asked the writer to define a moron. The definition given was "a moron is an individual who is capable of earning a living under favorable circumstances, but is incapable from mental defect, existing from birth or from early age, of competing on equal terms with his normal fellows or managing his affairs with prudence. He is able to do mental tests corresponding with the performances of a normal child from 7 to 12 years."

The question was then asked what possibility there was of such a feeble-minded person who had become a convert "making good" and holding permanently to the stand he had taken. After assuming the fact of the well-known mental instability and hyperexcitability of the subnormal

*Read at a meeting of the N. Y. Neurological Society, April 6, 1915.

class under discussion and the intimate relation between religious emotionalism and the psychosexual life the question was finally asked by the physician as to whether or not there was any psychological test that would adequately determine the possibility whether such a mentally deficient convert might not only radically change his moral reaction to his environment but that he might actually develop a strength of effort and purpose that might be lasting and effective.

The answer to this is positively that no such test exists. No Binet scale or even the remarkable series of Healy tests will settle the problem of the effect of an overmastering emotional or intellectual stimulus, any more than it can determine how far a long continued lack of effort and ambition has been the underlying cause of what appears to be purely mental deficiency in a given case.

A principal of Public School 168, Brooklyn, has developed a method of approach in the way of effective influence of defective children that is the most successful thing seen by the writer in five months' study of these cases in the public schools. He had an ungraded class of boys, nearly all of whom were poorly developed physically and clumsy or awkward in their movements and overgrown in their stature. Mentally they were mostly of the grade of morons. Nothing could have been more unpromising for results to be hoped for except a class of imbeciles or idiots. They were all morally troublesome or incorrigible at first. He devoted himself to special efforts in physical training. He also formed them into a basket ball team and in the course of time succeeded in making them the winning team of the school. As he expressed it, the gain in conduct was radical. They were changed from a set of incorrigible and disorderly boys into a decent, well-disciplined, self-respecting class. Muscular coordination had to be created in each one. Intellectually he stated that he had gained little and expected less. He believed that he had made men out of them. The facts on record proved conclusively that he had made each one of them over and that the intellectual gain was greater than he had realized himself.

The team work of the basket ball work seemed to have a socializing effect. And the fact of becoming winners at times and meeting on terms of equality the other boys was an overmastering influence in these special cases.

It is easy for one who has been trained in the use of clean-cut diagnoses and in the habit of using medical terms in common use in hospitals and neurological clinics to find his sharply defined conceptions badly obscured after a few months' work examining large numbers of mentally defective or abnormal children in the public schools.

Ungraded classes are now a well recognized part of the school organization in most cities. The sifting of the children who are doing unsatisfactory work in their grade is done systematically by the teachers. The final study of their mental deficiency or the physical or neurological causes responsible for these mental defects is being more and more assumed by medical advisors.

The Department of Health has the first chance to work over these children and in many cities covers the entire field. In New York and other cities the mental and neurological problems are now the subject of careful study of a few physicians specially trained in this line. All of us recognize that the so-called borderland cases partly mental, party neurological, are very numerous, but that there should be such an infinite variety of intermediate forms as to almost prevent any well-defined and sharply classified diagnosis is a problem both perplexing and serious.

Many terms formerly in use, apparently distinct and clear, seem to merge into one another, or are based on varying points of view, such as the etiological factors or dominant symptoms. Under such circumstances one may be pardoned if he turns with relief to more general and more comprehensive terms, such as atypical, subnormal, and abnormal children, or mentally retarded or deficient children; psychasthenic, or degenerate children; debiles or varying forms of the so-called psychopathic constitution. But after a painstaking study of about 1,500 children of the public schools in this city, of all grades of abnormality, certain facts begin to be too obvious to be questioned.

Certain phases of personality; certain reactions to the environment of the school, certain neurological conditions associated with definite mental types recur again and again. Some familiar and classical forms of disease well recognized by all of us appear very frequently or occur under marked forms that ought to be recognized.

Typical epilepsy will appear from time to time and is recognized as such quite as positively by the teachers as by physicians. But among an infinite variety of emotional outbursts or "tantrums" seen not infrequently in schools, uncontrollable reactions to ordinary school routine, both temperamental and intellectual, how often will it be possible to state with definiteness that this too is epilepsy and can only be scientifically classified as the psychic equivalent of epilepsy?

Within two weeks a boy of 9 years, of an unusually intelligent family of good social position, was seen by the writer in a school. He was, in the judgment of his teachers a candidate for an ungraded class, not so much on account of his failure in school work, or his mental deficiency as on account of his incorrigible behavior, which was characterized by disorderly conduct, emotional instability, a quarrelsome temperament, and spurts of temper. His past history included convulsions in infancy during a few weeks and nothing else of special interest. In my presence he had a typical attack of petit mal epilepsy, characterized by standing still, looking dazed, becoming unconscious for a few moments, rolling his eyes, twitching his facial muscles for a few seconds and then resuming his work as if nothing had happened.

Such momentary attacks had been by no means infrequent, were not considered of any serious import by his family, and had dated back to the time of his original major convulsions. His own sister was a teacher in the school. Without this distinct attack of petit mal the interpretation of his emotional reactions would have been difficult.

A second case, a boy of 11 years, showed similar symptoms as far as conduct was concerned, but he was much more incorrigible, more violent in the outbursts, variable in all reactions with a similar fair mentality, enabling him to reach a class up to his mental age. The Binet test showed only one year mental retardation. It was impossible to obtain any history of petit mal attacks and no general convulsions. His brother was an epileptic. He himself had suffered a serious traumatism to

his head, from which it was said he has never fully recovered. It may be interpreted as a possible case of psychic equivalent of epilepsy. It certainly was a typical case of the epileptic character.

Some form of motor abnormality will be met with among nearly every child who is submitted for examination to school physicians. Many of them are called by their teachers fidgity or restless children—and even normal children react in this way if tired or poisoned by the poor air of the school room. But under this term of fidgity or restless children will be found a large number of pathological conditions.

In the sense that epilepsy is universally recognized as a clinical diagnosis, Sydenham's chorea may without question be called a clinical entity and is to be seen in typical form in any class of children in a school. Corresponding to the psychic equivalent of epilepsy, it is not difficult to recognize a series of cases that may just as truthfully be termed the psychic equivalent of chorea.

The twitching of certain groups of muscles of the fidgety child may be indistinguishable from the muscular twitching of the child who has had definite Sydenham's chorea, but is improving. The same thing is true of the motor conditions in a child who is developing what will be in a few weeks definite Sydenham's chorea.

Out of the long series of children seen in the schools and clinics, one fact stands out positively and definitely, that there is a definite change in the mental condition of many of these children showing such motor irritability which may be called the psychic equivalent of chorea, and it is characterized by emotional instability, or irritability, by unstable or failing attention by mental fatigue produced after brief strain and by general weakening of memory, all of these symptoms occurring in a child who may have been fairly normal previously. This differs radically from the habit movements of defectives due, as sometimes stated, to a primitive arrest of psychosexual development.

Given a child with a motor irritability, some form of twitching, as stated, hardly severe or extensive enough to be characterized as Sydenham's chorea, a change in disposition and mental power, from a previously normal disposition and mentality, and a general deterioration of all school work after normal progress in previous grades and the diagnosis is possible. If confirmed by a history of so-called rheumatic attacks, a neurotic action of the heart, a valvular heart disease, or even attacks of acute tonsilitis, the diagnosis is probably correct.

This question is of vast importance. Such children are frequently subjected to criticism or discipline, or are wrecked for future efficiency by untactful methods. They differ from the average case of mental retardation, or mental deficiency by the fact that if properly treated they will recover. Treatment varies in each case. Often the ungraded class is a proper place for these children because the home or the street is the only other place a child can go to if temporarily excused from school. When the ungraded class ceases to be a retention pen for the lower types of feeble-minded children, idiots, imbeciles, and low moral defectives, it will be possible to use it for transient treatment for these neurotic types.

These conditions of masked epilepsy and chorea are mentioned to draw attention to an important question. In the broader view of the psychopathic constitution, or the more definite psychic constitutional inferiority, we will see both epileptoid conditions and atypical chorea, or various forms of tics and twitchings as an incidental symptom or by-product of the general condition, and they are sometimes classed among the stigmata of degeneration associated with the general condition. Are such terms as constitutional inferiority, psychasthenia, or even feeblemindedness to be regarded as adjectives, as syndromes, or as a diagnosis? Is the so-called epileptic character or constitution to be distinguished from constitutional inferiority?

The work of Warren Coleman in Bellevue in standardizing terms of medical terminology and diagnosis needs to be followed up in the study of atypical children, recognizing that when one observer speaks in terms of mental deficiency, another is emphasizing etiological, neurological, or physical conditions which underlie it.

An adequate study of the individual child who is thought by the school to be a candidate for the ungraded class, is based on six factors, each of which must be worked out as thoroughly as the available data will permit. First, family history, including the environment and general social status. Second, the previous personal history of the child. Third, the present physical condition. Fourth, the reaction of the child to his environments at home and at school, which is in simple language conduct or behavior or the moral status. Fifth, the mental peculiarities or deficiencies, the mental development in the past, and that which may be called his innate capacity for improvement. Sixth, the technical questions of the school and the child's relation to his work in the classroom, which is the pedagogical problem. This is not new. It is, perhaps, the general method of approach to the study of these children in all clinics where thorough work is done. But when this work is done under the conditions present in the public schools, the following phases of the work will be emphasized from necessity. The family history of school children may be unobtainable, but as a rule may be studied with far more assistance and far more thoroughly than in any clinic. There are many ways in which a teacher or a principal of a school can come in possession of data that often escape the physician. They are able to judge the influence of the family and home on the child. They know whether the parents cooperate with the school work or not and this means not so much whether the parents actively help the child as whether or not they actively or passively block the work of the school and the Department of Health. All teachers see the obvious results of parental alcoholism both as a phase of hereditary taint and the evidence constantly before their eyes from month to month of poverty and the shiftless family life with all its results. If a winter like the past puts thousands of fathers out of work, thousands of mothers take up the responsibility of supporting the family and the children must suffer neglect. In some sections of the city obvious loose living or notorious immorality of the parents is too common, even to complain to the Gerry Society or the police. As all the poorer families are notoriously prolific, and one child after another will surely appear at the school from the same family with the same heredity and the same bad environments at work, it is rare to find

a single subnormal child as the only defective in the family.

The older teachers will always notice the same types repeating themselves from a family of this sort. No examiner of children of ungraded classes would ever neglect to put on record the mental and physical status of the rest of these children. But here appears the greatest riddle of heredity unless it is a riddle solved by the Mendel law. Out of these tainted sources and from the worst and most tainted families appear some children who are perfectly normal or who are potentially normal. With their possibilities masked by environmental conditions the keenest diagnostic skill and endless patience is needed to distinguish these normal or potentially normal children from the constitutionally inferior children who will never under any circumstances develop normally or reach average mental capacity or a decent moral status. No greater mistake can be made than to consider the foreign, or lowest tenement house families, the most antagonistic or obstructive of the parents in their attitude towards the school. A large fraction of American families who belong to what one calls the middle class will obstruct and neutralize the best work of the school if they can. But there is no doubt that the Italian parents and certain allied nationalities are more difficult to manage than the others. If the compulsory education laws were relaxed for a week an army of Italian children would be on the streets or at work. Should we speak of a condition of hereditary illiteracy, the accuracy of the term would be questioned at once. And yet hereditary illiteracy exists. Every school in the city has a set of mentally retarded or abnormal Italian children who are in every way a difficult problem; for underlying their varying mental attainments they all agree in lacking an adequate interest in their school work. They have no interest in the work of the school compared with their work outside. They are predestined bootblacks, or it may be predestined sports or gangsters like their older brothers. Their parents, speaking little English, lose control over them as time passes. In many cases the interval between the arrival of the father and the rest of the family gave ample opportunity for the widespread infection by syphilis. Tuberculosis is conspicuously a racial disease among Italians in the tenements, and a general deterioration of an originally sturdy stock is only too evident.

In the schools this means that among every ten children of Italian parentage are several troublesome cases, some of them distinctly constitutionally inferior. No Binet scale or other standard of mental age adequately gages this vital point of effort and interest any more than it would distinguish between a race horse and a vicious balking or tricky horse. A child in one school who at 13 was unable to learn to read and write, has a father who could not read until after his marriage, when with the help of an intelligent wife he learned. Neither of them was mentally defective as far as could be learned. What is true of the Italians is true in the case of Greeks or other nationalities. The Scandinavians and Slavic races present other problems to the school peculiarly their own. The Hebrews differ from all of them. They not only want to get all that the school can give to their children, but in addition they keep their boys an additional two or three hours in a Rabbinical school, whether for purposes of religious or linguistic study may not concern us. It wrecks the health of hundreds of these children but is difficult to control.

Our approach to the study of present physical conditions of the school child can readily encroach upon matters much discussed by the Department of Health, and by every organization that endeavors in its own way to improve the health of the school child. As a matter of fact, no physician employed by the Department of Education dares for a moment presume that any physical examination of a child by the Department of Health in a public school is adequate for his own study of that child.

It will never be possible or desirable for the Department of Education to rival either the work of well-equipped clinics in dealing directly with the physical condition of the child or the general work of the Department of Health. It must use every possible means to learn exactly which of many possible physical defects are the direct factors in causing retardation or mental deficiency.

The conditions of the nasopharynx have not been neglected, as they are obvious. Discovering and correcting defects of vision has not been approached except in a casual and superficial way. By using the McCallie test for illiterates anyone in a morning's work can unearth cases of serious refractive errors never previously noticed. The test can be easily carried out by teachers or nurses. In many ungraded classes are children who have been struggling along five years or more with 50 per cent. vision. The same conditions are found among partially deaf children, though earnest efforts have been made to teach those who have been recognized as already deaf.

It has been difficult to know what results could be obtained if the recommendations of the physicians of the Department of Health were carried out and every effort was made by the school authorities to influence the parents to cooperate with their suggestions.

In Public School 110, New York, the principal, Miss Simpson, has been tireless in this work and in spite of the opposition from the parents has carried it on by tact and patience. Of about 100 cases seen by the writer a set of 46 children in the various ungraded classes had been subjected to operations for the removal of post-nasal growths, adenoids, and hypertrophied tonsils, and she reports the following statistics of the progress noted by her in these children:

Physical improvement, rapid and marked	86.9%
Physical improvement, slow and slight	8.7%
No apparent improvement	4.3%
Mental improvement, rapid and noticeable	80.4%
Slow, definite, slight	10.8%
No apparent improvement	8.7%
Improvement both mentally and physically	91.3%
No improvement whatever	4.3%

Of the various splendid attempts to meet the problem of undernourishment by means of school lunches, no exact statistics are available, or perhaps can ever be made. I may say that I have eaten the school lunches myself, and 9 cents bought more than I could eat. The quality was satisfactory in every way. Thorough treatment of the teeth of school children is only attempted in a few schools, though the danger of decayed teeth is being more and more recognized.

Every day the need of adequate physical training was seen and the general class drill has been carefully developed and is excellent. Never in

five months was it found possible in any individual case of a poorly developed child needing individual physical training to have it carried out unless some grade teacher would volunteer to do it in addition to her other duties, which is rarely practicable. The teachers of ungraded classes have far more instruction in physical training than teachers in regular grades, but even they are far too busy with other things to give much individual care. Such training is without doubt the only hope for many of the cases of mental deficiency.

It is peculiarly the function of those who work for the Department of Education to study developmental conditions. The motor abnormalities referred to already are but one phase of the greater problem of the physiology and pathology of development. The ideals of the department of physical training should in their own way when worked out, contribute much to this subject.

Each ungraded class has specimens of children who show evidences of extraordinary physical overgrowth and this is seen even among such stunted races as the Italians or Hebrews. There are endless varieties in these developed mental anomalies, including not only the overgrown but the obese, the undersized or dwarfish, the cretins, and the cretinoid types, such as the Mongolian idiot and the various forms of asymmetrical or local malformations.

Not unlike conditions are seen in every insane asylum, where normal looking men and women after a certain length of time under the influence of dementia or other psychoses develop marked changes in features, deterioration in the conformation of their bodies, hair or ears. These changes of physical appearance and general metabolism can be recognized not only by the physicians but by non-medical observers in cases of dementia and other chronic mental diseases. That mental abnormality or marked mental deficiency occurring during the period of early development in young subjects should produce even more startling results is not surprising and is an obvious fact to be seen in almost any school.

It is no coincidence that in almost every ungraded class one may find examples of one or more forms of every known condition that can be associated with disease of abnormal function of the ductless glands. In a single school visited on March 17 the following cases were seen:

Case I.—Stanley T., age 17, was of good family antecedents, one of seven children, all of them said to be normal. Birth was instrumental, infancy and early childhood were negative. In 1909 he was a strong boy, prehension 25 right hand, 50 left; tonsils enlarged; nothing else abnormal noted. In 1914 he was found by a physican of the Department of Education to be growing rapidly, wearing glasses for hyperopia, awkward in his gait, neurotic in heart action. At present he is 6 feet 2 in. in height, has enormous hands and feet. His nose originally retroussé has thickened and lengthened. His frontal bone and supraorbital ridges are enormously thickened. He has developed an unquestionable case of typical acromegaly after 6 years in an ungraded class. He presents various stigmata of degeneration, such as high arched palate, irregular pointed teeth, underslung jaw, and incoordination of eye muscles. He began school at 11 years but was never permanently in grade, entering an ungraded class in 1910. His attainments at present are reading equivalent to 3B; arithmetic to 1B, and he has improved in attention and memory. Physically he has developed in motor coordination. He is suffering from constant frontal headaches. His mental attainments as measured by the Binet scale are 6 years. He has never advanced beyond the mentality of an 8 or 9 year old child. Emotionally he is torpid. He is easily confused. He is deteriorating at present rather than advancing.

Case II.—Donald C., age 17, is 5 ft. 7 in. high. He has the same history of mental retardation and failure to develop from an early age as the previous case. He has not advanced beyond the mental age represented by his Binet test, 6 years. His mother died at confinement. His father and two sisters are normal physically and mentally. In 1908 he was anemic, a mouth-breather, but strong in muscular development; subject to some indefinite twitching which has disappeared. He has many stigmata of degeneration. Physically, he has the same tendency to overgrowth and the same enormous hands and feet and enlarged nose as the previous case, but he is not what one could ordinarily call a case of acromegaly. But he is a type of case to be seen by the score every month. Mentally he is a low-grade moron, who has been trained to fair involuntary attention and good auditory memory.

What is the meaning of this overgrowth? Is the anterior lobe of the pituitary gland to be suspected as in the genuine case of acromegaly whom he closely resembles?

Case III.—Edith G., aged 19 years, seen a few minutes after the two previous cases, comes from normal parents and is one of six living children, one of whom was born without a hand. Her early history is not fully known. She was seen in 1911 in the school and was 38 inches in height. In four years she has grown to 56 inches. She did not attend school until 1911 and remained in the lowest class for a year until placed in an ungraded class. She could not at that time read or write. She was regarded by all who saw her as a rather mild case of cretinism and was put under thyroid extract. She began to develop and has in 4 years grown 18 inches and has learned to read. She writes fairly well but slowly. At present she is showing in addition to a few symptoms suggestive of her former cretinism, exophthalmos, von Graefe's symptom, pulse 100, no goiter, perspiring hands. Her former hypothyroidism is changing to hyperthyroidism and it is not due to the thyroid therapy as that is said to have been stopped. Physically, her progress recently has been slow. Mentally, she is slow and has not advanced beyond her Binet age of 7. She has shown marked improvement in manual work. Her greatest delight is to make doll's clothing.

The heredity and the alternation from hypothyroidism to hyperthyroidism make this case interesting.

Case IV.—Bessie K., was seen by Dr. Smart in 1908. Her family history is negative; healthy parents; six living children all in school and all but Bessie making normal progress in their grades. In 1908 Dr. Smart noted that she had defective vision, enlarged tonsils and adenoids and valvular heart disease. Her speech was thick; she showed a slow reaction to all tests. She began school at 5 years, reached the third grade and was placed in an ungraded class in 1909 because of her poor attainments in all school work, and especially in arithmetic, where it was said she had no idea even of the form of the numbers. She was indifferent, showed poor attention and memory, poor general intelligence. During the last three years she has grown extremely fat in her face, hands and abdomen. Her height is 4 feet, 11 inches. She was not treated with thyroid extract. She has developed exophthalmos, von Graefe's symptom, nystagmus, pulse 102. Goiter cannot be distinguished from the mass of fat tissue in the neck. In this case a defect of the posterior pituitary lobe is probable, but a polyglandular condition is even more to be considered. Her mentality, which brought her to an ungraded class in 1909, has improved so that she is doing such excellent work in her class that she has been able to return to the regular grade, 4A. Her mental retardation was in part due to defective eyesight.

Case V.—Frances M. Father a letter carrier, healthy, mother appears sickly, has had three children, one of whom died of chorea and a "rheumatic heart." Home conditions are good. Her personal history records asphyxia at a difficult birth. Walking at two years. Talking not until five years. She developed symptoms of cretinism at about four years and even at an earlier date her mother noticed symptoms of mental deficiency. In 1912 a physician of the Department of Education recorded defective speech, adenoids, a slow shuffling gait,

and cretinism. In 1913 she was treated with thyroid extract but with no improvement. During the past year or two she has grown markedly obese, height 4 ft. 7 inches. In 1914 was given pituitary extract with beneficial results. She is now growing taller and is improving in many ways. She began school at six and never passed beyond 1A. She was put in an ungraded class in 1912 and has learned to read a few words but cannot write her own name or do any number work. Her chief element of progress was development of interest in her work and surroundings and improved muscular coordination. Before the pituitary extract was given the general indifference to her surroundings, and general mental deficiency were the chief points of her mental development. The pathological conditions may be ascribed in all probability to a polyglandular condition including deficient function of the thyroid and pituitary glands, posterior lobe.

Case VI.—Emma P., a girl, who was seen by the writer in private practice in 1908, when she was 17 years old, gave a perfectly normal family history, having intelligent parents, and four healthy brothers and sisters. Her mother gave a perfectly normal history of pregnancy, birth, infancy and childhood, excepting a general clumsiness and spasticity of the child which could not be explained by any traumatism at birth, and improved with physical exercises. She talked at sixteen months; walked at three years. She had no infectious disease but measles. She menstruated once at fourteen years; never again; nor did she show any physical or nervous symptoms corresponding to a suppressed menstrual period. Mentally at 17 she was intellectually normal, except a general slowness. She was dreamy, abnormally sensitive over unimportant matters. Her memory was good. She was a fine linguist. Her attention was somewhat wandering, especially in the subjects in which she was not interested. She was happy, affectionate, absolutely without the point of view of normal girls of seventeen. She was a great reader of books of interest to adults rather than to girls. No sexual trend of thought or action was noticed. She was informed of sexual matters but was not interested.

In 1911 an examination of the pelvic organs by a competent woman physician showed an undeveloped uterus about the size of a walnut, sharing in general lack of muscular tone and bulk the condition of the other muscles of the body. In general this may be considered a fair type of infantilism in a girl, closely associated with poor motor development, whose mentality, by no means deficient in many ways, by the aid of the best private teaching was brought to a high development. In the end at the age of 21 she was a purely asexual type of a girl physically and mentally. She has never menstruated. Much interesting work in the line of Freud psychoanalysis was done but without bearing on the purposes of this paper. In the schools among infantile types both girls with mannish traits, and boys with feminine traits will be met and need special study.

Every teacher of girls distinguishes at once the absolute difference not only physically but neurologically and mentally between those girls who begin to menstruate as early as 12 and those who are delayed to 16 or later. An arrest of mental progress shortly after puberty is by no means unusual. In a large number of women mental advance ceases at the time of childbearing. In many cases after puberty is established the same failure to advance or develop in any way may be noted, especially common among girls who are household drudges and among Jewish girls who are inclined to obesity.

No type of idiocy or imbecility is more definite or unvarying in its features than the Mongolian idiocy. The obvious resemblance to cretinism has long been a matter of interest and the failure of thyroid extract to cause any marked improvement is a definite method of differential diagnosis in cases of doubt. Some of the cases of Mongolian idiocy emphasized typical symptoms of hypothyroidism and in certain cases treated in the Demilt Dispensary with thyroid extracts the hypothyroidism disappeared, leaving the definite condition of a stunted child, with eyes far apart, fissured tongue, tapering fingers, and low grade mentality, which is called Mongolian idiocy.

In a case seen March 20 in an ungraded class in addition to the classical symptoms of Mongolian idiocy, were added distinct symptoms of hyperthyroidism, marked exophthalmos, rapid pulse. Another case was recently seen, aged $2\frac{1}{2}$, with some symptoms of Mongolianism superimposed on rickets and hypothyroidism with many gross stigmata of degeneration.

These cases are but a small number from a large series of similar types seen in ungraded classes, indicating not only that there are an extraordinary variety of conditions directly associated with abnormal function or actual disease of the ductless glands to be found among school children, but that there is a marked tendency to polyglandular diseases, or shifting of the symptoms commonly associated with one ductless gland to symptoms peculiar to another.

But by far the commonest condition is that tendency to coarse overgrowth in morons who by 12 years of age are as tall or taller than their parents, and present definite hint of an involvement of the anterior lobe of the pituitary gland.

Among girls hyperthyroidism is not only fairly common but is usually unnoticed by teachers and by the physicians of the Department of Health until the extreme nervousness, rapid heart action, genuine goiter, and marked exophthalmos have become too far advanced to react to simple therapeutic measures.

It is certain that no adequate study of atypical school children can be made without mastering the general problem of the normal or abnormal reaction of the child to the strain of puberty and adolescence. The relation of the thymus gland to the development of puberty is one of the most interesting and obscure parts of the physiology of the ductless glands. Perhaps a third of all the cases of mental abnormality seen in the schools are near or at the period of puberty.

It is probable that no adequate knowledge of hysteria in girls or adults can be gained that does not recognize the persistence of infantile states of mind. That the elaborate phantasmagoria associated with Freud's psychoanalysis has a basal relation to abnormal physical conditions and to abnormal sexual development is only common sense.

It is undoubtedly true that in the schools two divergent types may be seen among boys associated with a premature development of the sexual glands and their functional activity, or on the other hand their delayed development. This may well be the cause of or correspond with the failure to advance from the stage of infantile libido towards the parent to the adult heterosexual interests.

The cleavage between children of a shut-in personality and those who are social in their instincts may be associated with this same physical sexual development. In a sense the "self concerned" or so-called "narcissus" stage remains in one case permanent. In the other the self-centered or egocentric stage is outgrown and the normal social life is entered in at an early stage long before the normal heterosexual life is reached.

Whether the basis of this cleavage is to be attributed to somatic variations alone or to psychosexual inferiority is a question not easily answered. It is held by some that psychosexual inferiority is constant while the physical or mental deficiency

may be obvious or may not exist at all. Whether or not the premature or delayed sexual development makes a definite cleavage in the mental and moral development of the two types of children, it is a fact not to be questioned that the psychology of the child who from infancy on to adult life has been a part of a group, reflecting the varied characteristics of the crowd is radically different from that of the child living from choice or necessity by himself, developing what is generally called an egocentric or "a shut-in personality." Each type may develop along its own lines of normal growth or may develop abnormal or thoroughly morbid traits of mind or conduct. By far the majority of adult psychoses appear in those who had the "shut-in personality."

From these physiological variations during the period of puberty, or during the period that preceeds it or follows it, we are drawn to the special study of conduct. Much of the behavior of the child in school, and his reaction to discipline of both home and classroom is devoid of pathological interest. In the children proposed for ungraded classes the entire record of behavior must be studied and frequently it is that alone that has made his school career a failure. To judge a child on the strength of his work in the classroom alone is folly. The standardized tests for mentality in general use ignore personality and general conduct.

It is natural that the conception of what constitutes dangerous traits and abnormal actions will vary in different schools. In the judgment of some teachers a boy who is always fighting or bullying or is impudent is a menace to the welfare of the school. In another school stealing, or general dishonesty are common and the influence of the gangs of neighboring streets is a dangerous factor. In another school minor or major sexual offenses are common. The collections of postal cards removed from the children are obscene. They will be found in girls' desks. In another, vices such as drug-habits run riot.

It is easy for teachers or others to exaggerate the importance of these misdeeds or to ignore them totally. The fact cannot be questioned that of the criminals of 1925, a fair fraction are in the public schools to-day. Of the prostitutes of 1925, a still larger fraction are in the public schools to-day.

An example of what might be called simple misbehavior of a school boy without any special pathological interest was brought to our attention in the case of George F., who in 1913 threw an eraser at a teacher who was passing him in the school yard, striking him in the face. There was no reasonable explanation for the act and he was not caught at the time but confessed to save another boy who was wrongfully accused. He was punished by being compelled to apologize before the entire school which he did in a manner that left an impression of his being an unusually manly boy. He graduated at 13 and went to work. The case was submitted to the writer not over a month later for mental examination on account of a most foolish persistent series of petty thefts of sheets of postage stamps and cigarettes which cost him the loss of a splendid position. A thorough study of his case proved that he had an excellent family history. He had always been healthy and strong and had been most carefully watched by his mother. He was in the boy choir of a neighboring church and was highly thought of. He was accustomed to active physical exercise. Four years previously he suffered from a superficial pistol wound in the forehead said to have been the result of an accident. He was arrested for this and at another time for playing ball in the street. In 1910 when at the age of puberty he became "sassy," made trouble for his mother; masturbated occasionally; was expelled from the Y. M. C. A. for unruly actions which the director said were nothing but boyish high spirts and disorderly conduct. In 1912 he stole $5 from his mother and bought a watch but never stole again until the theft of the stamps. His mother said he was rather of a secretive stolid nature and did not appear to regret his misdeeds very much; though he cried and repented at the time. He was confirmed in 1912 in the Episcopal Church. He never had much interest in girls or parties. He had been in many fights in school but recently the gang in the neighborhood "had it in for him" and he stuck to his house after school hours or went to the Y. M. C. A.

A careful psychological examination was made without any definite results. He was normal in attention, memory, reasoning faculties. His Binet test was over 12. He was absolutely lacking in imagination by every test. He showed some emotional deterioration. For 2 years he had been sulky. He had no adequate appreciation of the contradiction that a boy recently confirmed in a church should be getting into such scrapes. He stated that it was not fair to the rector but could not explain the cause of his misdeeds. If any mental conflict, or underlying sexual problem existed, it was not revealed. The keynote to the explanation of his later trouble was his foolish scrape in school; and that in turn was due largely to instability of the period of puberty.

That a large percentage of the cases of genuine delinquency, or of persistent incorrigible or immoral conduct, has a definite association with mental deficiency that can be demonstrated by accurate standardized tests is undoubtedly true. The type that is most constantly present in the schools and repeatedly submitted for special examination for supposed mental deficiency, is apt to be a type of a boy, or girl, who is the child of parents unfitted in every way, physically, morally and intellectually to have normal progeny. The children are from the earliest years of school life constitutionally inferior. Physical poor development and later physical deterioration are obvious. Mentality may be low grade, but often is fair. Such emotional instability exists that self-control is impossible. Volition may be weak; or there may be most marked exaggeration of self-will.

Underlying this is the lack of interest in school and rebellion against all restraint of the school and a tendency either to quarrel with or bully the other weaker children, or to yield absolutely to the control and influences of those capable of corrupting them in various ways.

The importance of definitely making a positive diagnosis of psychic or general inferiority in these cases, and some positive study of their tendencies is that it carries with it a prognosis of a future much more dangerous to others than any type of mere mental deficiency. There is always hope for reform among many types of criminals and other delinquents, but the permanent reform of these cases of genuine constitutional inferiority is questionable. Deterioration is more probable than any possible improvement. Many cases of dementia precox may arise from among them.

The possible variations of conduct in school children are infinite in variety. The toxic conditions are of special interest because in addition to poisoning by nicotine and alcohol, there has been added a new and dangerous form of drug habit, which is met with from time to time in the schools, though difficult to prove, usually consisting of cocain or heroin or a combination of the two called "coke." It is difficult to prove, but alternation of excited and depressed moods is suggestive. Periods of stimulation alternate with a sleepy or nervous condition.

A case of a boy, age 18, was brought to the Demilt Dispensary a year ago on account of epilepsy. He gave a good family and personal history and had his first fit January, 1913, apparently a typical epilepsy of the grand mal type, general in character, with aura and definite symptoms.

The boy had been associated with Calvary Church, had been in the choir and was highly thought of. He had become unsettled in his work, left several good jobs without cause. His school record was negative except failing in promotion two times. It appears that he had become associated with a questionable street gang and recently had developed the habit of petty stealing. The rector of the church called to inform us that the boy had the cocain habit, which his father confirmed. He was scared out of the habit and the epilepsy ceased. For a year he has been doing well, is working steadily and has improved physically and mentally. Lacking the etiological factor of cocain poisoning this case would serve as an example of the epileptic character.

The epileptic character as distinguished from the epileptic psychoses and the psychical equivalent of epilepsy is of infinite importance in an adequate appreciation of the problems of behavior met with among school children. Healy distinguishes this definitely, stating that the epileptics are prone to emotionalism, but that much inconstancy is shown in their feelings. Some are subject to constant irritability, but more often there is a sudden showing of anger or vicious conduct entirely without cause. Periods of sullenness or bad temper may be prodromata of actual attacks, and in some cases it seems certain that ill feelings and their reflection in mental disposition vicariously replace the attack. Impulsiveness is constantly seen. The ego centric tendencies are noticed by many. Self-love, self-assertion, defective appreciation of the rights of others, or excessive obstinacy are frequent. Their ethical perceptions are limited. He defines the blunted moral sense as a combination of mental deterioration and overwhelming impulsions. In every way epileptics tend to antisocial behavior, but are notoriously incalculable in their moods and impulses. The later psychic conditions vary all the way from twilight states characterized by foolish and unnecessary lies to quite irresponsible conditions of altered personality, and violent actions.

L. Pierce Clarke defines the epileptic temperament as a particular type of constitutional makeup which he thinks antedates the occurrence of the first epileptic fit. This makeup is predominatingly infantile in the emotional sphere of development. The affective defect is due to infantile psychosexual immaturity. The mind always remains of a simple child pattern. "The epileptic," Clarke continues, "has no marked scruples or doubts of the obsessive neurotic; he is not burdened with inhibitions or prohibitions, unhappily his personality permits him to become self-engrossed with lower animal instincts or passions. With the inhibitions reduced and with an over-emphasized estimation of his own importance and ability the epileptic finds himself in constant conflict with the outside world. He is furthermore attached to an infantile emotionalism because he is usually possessed of little or no constructive imagination."

The problems of the study of purely mental conditions observed in children who are in ungraded classes include every phase of psychic retardation and mental deficiency. These cases, whether higher or lower forms of feeblemindedness, have been thoroughly studied by many authorities of late, and have been subjected to much careful investigation with recent scientific methods.

Most interesting and perplexing are those cases of children who appear to casual observers to be normal and yet have some special defects in certain studies. If this should be in arithmetic, for instance, common experience of all will recall many cases where failure to comprehend even simple process of arithmetic seems quite compatible with perfect intellectual attainments in other lines. If, on the other hand, it happens to be an absolute failure to learn to read, spell, and write, it is hard to accept any statements of normal mentality. Before the Binet and other standardized tests were in use this was not so easy to demonstrate. But sometimes this defect in reading appears so definitely that the name "word blindness" will be glibly used to cover these cases. Children who have been in private schools often appear to better advantage during tests, and in their schoolwork are passed along in spite of obvious deficiencies. Much may be made of the relation of the interest a child takes in a certain branch to his success.

Two years ago two boys, who were twin brothers, aged sixteen years, were examined at the department of ungraded classes; they were adopted children of a well-known writer. Their real family history was unknown, but since the time of their adoption at the age of one they had been well cared for, had not been sick, excepting for an attack of typhoid fever at six years developed by one of them, and an abscess of the leg two years ago. They were both splendidly developed physically, well behaved, good looking boys, with no defect in the special senses, or in their speech, and not only normal but athletes in their muscular development. Their education had been carefully followed out except that they had been changed from one school to another far too frequently, and from eleven to thirteen were traveling around the world. For the last two years they had been at a fashionable boarding school. They were both ready talkers on subjects that interested them.

They were totally unable to spell any words but a few monosyllables. They were not especially deficient in arithmetic and gained good marks in that subject. Their attention was fluctuating, but was rated as fair voluntary attention. Their memory was good for recent and remote events and they could recall seven digits. Emotionalism was normal. They were affectionate and not excitable. Their general intelligence was about that of an average boy in a boarding school of their age. In testing their spelling no special difference was seen between auditory and visual memory; they had started in a school originally where a so-called phonetic method was used. Binet test showed a mental age of about eleven. Various special tests were made, but the general condition remained as stated, two boys apparently of the average mental capacity of their school mates, who were unable to spell at all or read more than a child in the lowest grades.

Some definite failure in the association tracts between visual, auditory and vocal centers was presumably present.

In these cases and others examined there appeared to be some individual difficulty in clearly noticing

the special sounds, or shapes of letters or words, and a failure to recall these special distinctions in shape or sound. Such a difficulty is normal in the average child of three or four years. It persists in the illiterate, but is an anomaly among school trained children. Why it is not much rarer is a question hard to answer. Even morons of a low grade often learn to spell better than these boys did, and in all other lines of mentality, unless the Binet test in these cases is accepted as positive, they were higher than morons.

In the public school they would have been placed in an ungraded class before they were twelve years old. In a private school their defect did not seem to make very much difference to their teachers or to them.

It will be impossible even to outline the many abnormal mental states seen in these school children. Psychoses are often suspected. Deterioration to the extent of definite dementia precox was occasionally seen. It was difficult to make a positive diagnosis in cases that seemed to gradually fade into dementia precox from the condition of a low-grade moron or imbecile. In some cases apathy, aboulia, and negativism superimposed on the previous mental deficiency made such a diagnosis possible. The condition of so-called predementia precox was seldom possible to diagnose with positiveness or to actually distinguish from certain types of constitutional inferiority.

Various forms of insanity common in adult life may be met with during childhood, though very infrequently. Certain affective psychoses may develop at the period of puberty, and during the adolescent period. Often they conform so closely to an exaggerated adolescent instability that it is not always easy to say whether the general diagnosis used in adult cases should be made, or the more limited one of a phychosis of puberty or adolescence. To untrained observers hysteria at puberty or during adolescence may appear to be definite insanity. The converse is true. Many adult phases of mental disorder are a reappearance of infantile or childish mental states.

Most interesting of all studies of mental abnormality in children the adequate observation of the various mental conflicts in school children especially at the age of puberty could rarely be adequately carried out in these cases. What one notes as peculiar behavior or mental abnormality can be explained after thorough work as a not illogical development of some hidden conflict or fixed idea.

The so-called psychoses of puberty are often due entirely to such hidden mental conflicts.

We commend such cases to the patient and sympathizing care of any one who can give them adequate attention. It is difficult to imagine a staff of alienists in the Department of Education so highly trained in psychoanalysis and with so much leisure time at their disposal that they could make any adequate study of many of these cases of obscure mental conflicts met in the schools from week to week. There are very few clinics in the city that can do the work. Many principals of public schools in their own way often without any psychological training are trying to do the noblest type of personal work with these children in what is really suggestion or re-education.

In general, the adequate treatment of a child who has failed to adjust himself to his environment in the public school is analytical, educational, hygenic, dietetic, and medicinal. To this may be added environmental, as many of these children need far more a prompt removal from their entire home influences than anything else. This will rarely be possible except in the case of families who can send their child to a private boarding school. The regulation not only of environment but friendships is fundamental. The custodial institution that offers itself as an alternate to home and street influences may wreck the child morally.

The department of physical training, by means of various forms of outdoor athletics or gymnasium training may let off the storm and stress of a naturally restless or over-anxious mental makeup. A sublimation of the "libido" into useful interesting occupations is above all things to be aimed at.

In conclusion we would express our gratitude to Miss Farrell, who is in charge of the Department of Ungraded Classes of the Public Schools of New York, for permission to use the case records of the children who have been examined. Words cannot adequately express the appreciation of all who know to what extent the entire credit of that work in New York City is due to her executive ability and energy in developing the elaborate system of ungraded classes of this city now in existence.

In calling attention to physical factors, especially to problems of development and particularly motor abnormalities, it is with the hope that in these lines the most promising work can be done. In conditions associated with the ductless glands, cures are sometimes obtained in types that have seemed too low grade for hope in the past. In a detailed study of the moral problems of the school child society in general may well take an active interest, for it will mean far more to society than the refinements of purely psychological study of cases of intellectual defects alone. But in reality no sharp distinction should ever be made between the neurological, mental, and moral problems.

THE CURE OF GOITER BY THE INJECTION OF BOILING WATER INTO THE SUBSTANCE OF THE ENLARGED THYROID.

By JOHN A. WYETH, M.D., LL.D.,

NEW YORK.

SURGEON-IN-CHIEF TO THE NEW YORK POLYCLINIC MEDICAL SCHOOL AND HOSPITAL.

When, at the meeting of the American Medical Association in New Orleans, in 1903, I first made public the curative effect of water, at a high temperature, injected into the substance of otherwise inoperable angiomata, in the discussion which ensued, it was suggested that the method would prove equally efficacious in the treatment of goiter. A number of successful cases have already been recorded, especially by Dr. Porter of Fort Wayne, Ind., and Dr. Reder of St. Louis.

The technique employed in a recent case at the Polyclinic was as follows: The skin and the area to be injected were thoroughly anesthetized by the injection of a free quantity of a one-half of one per cent. novocaine solution. One of my steel syringes, taken out of the boiling cauldron, was filled with boiling water, which was immediately injected by inserting the needle well into the substance of the mass. To prevent scalding the skin, as heretofore advised, the contiguous surfaces are shielded by a

covering of towels, leaving only the point of injection exposed. As the steam or water is apt to escape from the needle, as it approaches the skin, a gauze swab is held as a shield in front of the needle, which latter is thrust through and into the skin, when the contact is made. From 10 to 20 minims are forced out in one spot. The needle is then *partially* withdrawn, and the point carried to a new field, and the injection repeated.

Three or four such areas may be injected at one sitting, and these may be repeated as required, in one or two weeks, and so on, until the tumor disappears.

In the case in question, five injections were made in ten weeks, and in three months the goiter had entirely disappeared. The pain was insignificant. There is very little danger of having the water too hot. A Bunsen burner or an alcohol lamp held under the barrel of the syringe just as the needle is being inserted will insure a high temperature. It is advisable not to have the point of the needle immediately under the skin, as the excessive heat so directly applied may produce necrosis, which is apt to become a point of infection. If the skin covering remains intact, all tissue coagulation or destruction, being aseptic, is harmless, and the solidified mass gradually disappears by granular metamorphosis. It goes without saying that important vessels and nerves, as well as the trachea, should be avoided.

I have used the method now in a large number of angiomata, since its introduction, nearly fifteen years ago, and have never had a fatal result or accident, beyond some slight burnings of the cuticle. In a single instance, as a precaution, I threw a temporary occluding ligature around the common carotid and the internal jugular. The great heat of the injected water, although seemingly in immediate contact with these vessels (in the case of a very large venous angioma of the neck, just below the jaw) caused no coagulation, and the ligatures were removed.

In the demonstrations at my clinic I often use the ordinary glass hypodermic syringe, which, being gradually heated with the water, will not break.

I am of the opinion that the majority of goiters can be cured by this simple method. So far, I have had gratifying results in every case of venous or arterial angiomata. The capillary form (mother's mark), especially those on the face, always undergoes more or less necrosis and infection, and while the vascularity is arrested, a secondary operation to secure a linear cicatrix is usually necessary.

244 Lexington Avenue.

THE IMPORTANCE OF THE EARLY RECOGNITION OF THE MENTAL LIMITATIONS OF THE PRECOX TYPE.

By J. R. ERNST, M.D.,

WASHINGTON, D. C.

JUNIOR ASSISTANT PHYSICIAN, GOVERNMENT HOSPITAL FOR THE INSANE.

The development of many of the psychoses could be retarded and possibly prevented by the early recognition of the child's mental limitations and the type of his mental make-up. The "shut-in," or precox type, is familiar to all. A child of this type, prior to puberty, usually excels all others in his classes; the parents, in ignorance of the impending crash, urge him on; the teacher, equally ignorant, cooperates with the parents in hastening the child's mental destruction. The child, thus encouraged, puts forth his best efforts, and as a result his limited amount of potential is used up and a deteriorating process begins. His mental powers gradually decline and he becomes the object of unjust criticism; parents, teachers, and friends alike join in calling him lazy. They appeal to his pride, recall his past successes, and by every possible means urge him to resume his previous intellectual status; but the damage is done; the fire burned brightly, but it was built of straw.

I believe if this child's mental make-up had been thoroughly understood by parent and teacher, his mental life would have been prolonged; the potential with which he was originally endowed, even though less than normal, might have been added to and built up, and he would have been able to reach maturity with normal or nearly normal mental powers and would have become a useful member of society, instead of a subject for institutional care for probably the remainder of his life.

If this type of individual grows to manhood without intelligent recognition of his condition and without proper training, he is easily recognized because of his tendency to come into conflict with his environment. Because he is unable to come into natural and free relation with the realities, he is constantly getting into difficulties and is peculiarly adverse to discipline of any kind. Another well-known characteristic is his actual need of alcoholics or drugs—one or both of these he uses regularly and very frequently to excess for the purpose of reinforcing that gradually failing potential, which, if properly conserved and directed during his earlier years, would not have failed him at this time.

It is men of this type who most frequently desert from the military service and are the least amenable to discipline; who serve a large part of their enlistment period in the guard house, or suffer dishonorable discharge.

This constant conflict eventually brings about the development of a psychosis, with the result that the individual's period of usefulness is cut short and he spends the greater part of his life a burden and expense to the State.

As stated by White*, "Every individual born into the world has, if it could be determined, a definite potential for development. The force of the impetus which starts it on its path is sufficient to carry it a certain definite distance. The predetermined goal, in each case, will be reached if no accident intervenes to prevent. In the subject of this disease, the original impetus has been weak, only sufficient to carry them a short way, and when its force is spent development stops and the retrograde process is hastened, or perhaps immediately initiated by some special physical or mental stress occurring at the critical point of puberty and adolescent evolution."

As this statement is the accepted belief of all psychiatrists, it will serve as an added proof of the great importance of recognizing in early childhood the precox type of individual.

As the potential of this type is limited, the child having "just sufficient to carry it a certain distance," every effort should be made to conserve it. As the majority of the precox type do not break until puberty is reached, and the increased demand

*"Outlines of Psychiatry," by William A. White, M.D., fourth edition.

incident to the unfolding of the sex is brought to bear upon the highly organized nervous system, it is reasonable to suppose that this "stranding on the rock of puberty" might have been avoided, at least in a certain number of cases, if proper measures were undertaken, during the years preceding puberty, to conserve the potential instead of encouraging the precocious child to squander it recklessly in order to attain what at best can be but a temporary and fleeting success.

The present public-school system, with its crowded curriculum, and a corps of teachers absolutely ignorant of the mental limitations and the type of mental make-up of the pupils entrusted to their care, is undoubtedly responsible for a large percentage of exhausted intellects and ruined careers.

The early history of almost any case of dementia precox will furnish ample proof of the total lack of understanding of the mental limitations of this type by those immediately concerned in their mental development. The following early history of a case is fairly typical:

Case No. 19883: The subject attended school between the ages of five and sixteen, failing promotion once and reaching the first year of high school. After leaving school, he was employed in a number of clerical positions, from several of which he was discharged on account of incompetence. At the age of twenty, he enlisted in the navy. Seven months after enlisting, when on shore leave, he spent a night in drinking and sexual excesses. Returning to the ship the next morning, he attracted attention by jumping overboard. For the next few weeks he was unable to answer questions intelligibly, talked constantly about sexual matters and carried on filthy practices with his excreta. He was transferred to this hospital six days after this sudden change in his condition.

I cite this brief history because it is typical, and because a few of the factors responsible for the mental downfall of this individual are set forth, giving an opportunity to point out the errors in his early and subsequent training. In the first place, we find this patient starting to school at the age of five years. While the history is incomplete regarding his early mental status, it is reasonable to assume, because of the early age at which he entered school, that he was somewhat brighter than the average child. At this point in the mental development of the patient there is no doubt but that an intelligent understanding of his limitations, by parents and teachers, would have resulted in his being kept at home until he was at least eight or nine years of age. There is no doubt but that a delay of four or five years at this time, combined with a proper understanding of his limited amount of potential, and a carefully regulated life, would have prolonged his period of usefulness many years.

The peculiarity of the pathological changes in nerve tissue in mental disease depends upon the fact that when certain elements are destroyed they are not replaced or are replaced only in part and very slowly. Hence the great importance of the early conservation of these elements in the individual whose supply is less than the average, due to an hereditary taint of insanity, or to alcoholism, or to neurotic tendencies.

In the further consideration of the patient's history we find him failing one promotion and unable to complete the first year high school before he was sixteen, when the average child is in the third or fourth year. This fact alone would have been sufficient warning to those who have studied the type; and if in addition a thorough knowledge of the family and personal history had been obtained, the disastrous consequences which followed might have been foretold and avoided.

As we consider the history further the evil consequences of this lack of appreciation of the patient's condition, become more and more apparent. He is urged to secure a position. Of course, he fails. He secures another one, with a similar result. Eventually when he has found himself to be totally incapable of success on his own initiative, he enlists in the navy, largely with the hopes that a shifting of the responsibility to some one else will make life less of a conflict. In this he is entirely in error, and soon becomes aware of the fact. As he is peculiarly antagonistic to routine and discipline, the conflict instead of becoming easier, becomes intensified. In despair, he seeks to dull his senses and forget his troubles by becoming intoxicated. He finds in alcohol the necessary aid to the dulling of the conscious. It eliminates the necessity of adjusting and life is easier. He becomes a chronic alcoholic with all its attendant social evils, and deteriorating effect on the higher conscious centers. He eventually attempts to end it all by jumping overboard, thereby admitting defeat. He is prevented and confined to this institution, where at the age of twenty-one, when his period of usefulness should be just beginning, he awaits the end.

In conclusion, I will say that in view of the great importance of the early recognition of this type of individual I believe that if more time and effort were expended in the study of the child and his limitations and the hereditary and prenatal causes of insanity, a far more lasting good would be done to humanity than that which is attained by the elaborate and detailed analysis of the mental processes after the damage is done. In making this statement I fully appreciate the importance of a thorough study of the pathology of this disease and have no intention of minimizing the importance of the work that has been and is now being done relative to pathological mental processes. This article was written with the hope that it might be the means of arousing more interest in the study of the child and his mental limitations.

An important factor in the early recognition of this type of individual is the school physician. Every child should be interviewed personally by the physician at least twice during the school year; a thorough family and personal history should be obtained and any hereditary taint ascertained, and if the child is of a highly nervous temperament, or shows any of the characteristic features of the precox type, special care should be exercised in his mental training.

In all other diseases, prophylactic measures are now considered of paramount importance. Large sums of money are expended by cities, States, and nations, and large and expensive organizations are maintained for the purpose of preventing disease. This extensive system of prophylaxis is of comparatively recent origin. It was brought about by extensive and detailed research and the directing of every effort to ascertain the cause of disease, with the result that prophylaxis became of first importance and the treatment secondary.

In the field of mental disease, scant attention has been given to the conditions necessary for the production of a normal healthy mind, and yet it is the universal belief that, "There is nothing great in the world but man, and nothing great in man but

mind." On the contrary, the greater effort is now being directed toward a study of the mental wrecks which have been produced by ignorance on the part of their progenitors, and a total lack of interest by the great majority of people in the fundamental causes of insanity. Quite likely the time is far remote when eugenic marriages will be the rule, and a child, bearing the handicap of a weakened intellect will be the exception, therefore we can but encourage and take part in the campaign of education now going on, hoping that when the individual has a better understanding of these things, he will bring about his own salvation.

NOVOCAIN - SUPRARENIN INFILTRATION - CONDUCTION ANALGESIA IN THE REPAIR OF INGUINAL HERNIÆ.*

By ISADORE SEFF, M.D., F.A.C.S.

NEW YORK

ADJUNCT ATTENDING SURGEON, BETH ISRAEL HOSPITAL

ALTHOUGH local analgesia in operative procedures for herniæ of the inguinal region is now used more extensively than in former years, especially since the introduction of the nontoxic novocain in combination with suprarenin, nevertheless, a large number of the medical profession is still not convinced that complete surgical analgesia can be obtained in this region. Such pessimism is entertained by those who have witnessed the unsuccessful use of local anesthetics in the hands of surgeons who have not familiarized themselves by practice and experience with the various methods and their limitations.

It is my purpose in this paper to report on the results obtained with the infiltration-conduction method in twenty-three cases of hernia of the inguinal region operated upon at Beth Israel Hospital, and to speak of its advantages as contrasted with the older method of local analgesia, namely the neuroregional method.

The Neuroregional Method.—Hall and Halsted in 1895 demonstrated that the injection of a solution of cocain into any part of the trunk of a nerve is followed by sensory paralysis in the entire peripheral distribution of that nerve. This paved the way two years later for the development by Cushing of the neuroregional method of producing local analgesia. Cushing followed the Reclus and Schleich method. He infiltrated and incised the tissues, layer by layer, freely exposing the inguinal canal and the nerves, which lie under the external oblique fascia, namely the ilioinguinal, the iliohypogastric, and spermatic. Into each of these nerves at their entrance into the operative field, *i.e.* at the upper part of the inguinal canal, a solution of cocain is injected. The conductivity of the nerves being thus blocked, there is produced a loss of sensation in the hernial sac, the coverings of the spermatic cord, the testes, and a portion of the skin of the inguinal region.

Although the superficial position of the parts and their anatomical arrangement are most suitable for the neuroregional method, yet the analgesia usually obtained is not very satisfactory. This may be due to the size of the hernia or what is more important, lack of knowledge of the normal and abnormal location and course of the nerve supply of this region. Because of these difficulties the method remained in the hands of only a few trained specialists.

*From the surgical service of Dr. Charles Goodman.

The Infiltration-Conduction Method.—In 1905 Braun of Zwickau described this method. It is based upon the principle that every infiltration of connective tissue with local anesthetics produces not only infiltration-anesthesia in the area injected, but also conduction-anesthesia in the area of distribution of the nerves that are contained in that tissue. This method requires the infiltration of the tissues through one or more punctures and the circumjection of the operative field. It eliminates the infiltration and incision of the tissues, layer by layer, and does not demand an accurate knowledge of the location, and the injection of the individual nerves supplying the operative area, upon which the success of the neuroregional method depends.

Technique of Braun's Method of Infiltration-Conduction Analgesia.—Two points are selected for the infiltration of a ½ per cent. solution of novocain with 5 to 8 drops of a 1-1000 solution of the synthetic preparatino of suprarenin to the ounce. Point 1 lies three fingers' breadth, or about two inches internal to the anterior spine of the ilium. Point 2 is over the ramus of the pubes at the external inguinal ring. At these points the solution is injected endermically, producing a wheal. Through the wheal at Point 1 the needle is passed perpendicularly through the aponeurosis of the external oblique and the muscular layers of the internal oblique and the transversalis. The needle is then withdrawn from the depth to the level of the subcutaneous tissue, and again inserted, at least twice, but more obliquely into the muscular layers previously mentioned until it strikes the iliac bone. The thick muscular layer in this region must be well infiltrated to block the ilioinguinal and the iliohypogastric nerves. To accomplish this about 20 c.c. of the solution is required. To anesthetize the terminal nerve branches a further injection of 10 to 20 c.c. of the solution is made from Point 1 under the aponeurosis of the external oblique in a fork-shaped manner toward the ilium and the median line of the abdomen. From Point 2 a deep injection of the solution is made in a fan-shaped manner, so that with each injection the needle will strike the pubic bone. Also from this point 10 c.c. are injected in a fork-shaped manner under the aponeurosis of the external oblique into the inguinal canal and alongside the spermatic cord. The next step is the subcutaneous infiltration of the operative field in the form of a rhombus from Points 1 and 2. The entire infiltration requires 60 to 100 c.c. of the ½ per cent. novocain solution, which amounts to from 5 to 7½ grains of novocain.

In our series of cases we have had no toxic effects from these large quantities. The time required for obtaining complete analgesia of the operative field is about fifteen minutes.

Our own technique in the main followed that of Braun. A hypodermic injection of 1/6 of a grain of morphine sulphate and 1/150 of atropine sulphate was always given one hour before the operation. We have modified the method to the extent of adding one step in the production of analgesia. After the hernial sac was incised and the contents returned into the abdominal cavity the analgesic solution was injected into the peritoneal surface of the neck of the sac. This prevents the pain which is usually experienced by the patient during the manipulations necessary for isolating the sac. It also blocks the impulses which results from traction on the peritoneum, and thus eliminates the occurrence of nausea.

The use of either the neuroregional or the infiltration-conduction method requires a more definite knowledge of the anatomy of the inguinal region than is necessary when one operates under general anesthesia, since with local anesthesia the patient is conscious and the surgeon must handle the tissues more carefully. The traumatism of the tissues being thus considerably reduced the process of repair is probably shortened, and the danger of wound infection largely eliminated.

Up to the present time we have met no contraindications to the use of local analgesia. It is of undoubted value in cases of incarcerated and strangulated hernia occurring in old and debilitated patients, and more especially in those suffering from pulmonary, cardiac, and renal affections where general anesthesia is usually contraindicated. Neurotic individuals who often fear the inhalation of a general anesthetic and its after effects readily submit to local anesthesia when they are assured by other patients that no pain is experienced during the operation.

In the series of twenty-three cases of hernia of the inguinal region operated under the infiltration-conduction method of local analgesia we have observed the following facts:

Operative Method Used.—We operated in twenty cases according to the Ferguson method of repair of inguinal hernia. Two cases were operated upon according to the Bassini method, and we found that although the cord was handled the results were just as satisfactory. There was no pain during the operative procedure, no postoperative catheterization, and no abdominal distention. One femoral hernia was operated upon through the regular inguinal incision with similar good anesthetic effects, and entire absence of postoperative pain, nausea, and vomiting.

Age.—The ages of the patients ranged from two to fifty-six years.

Postoperative Pain.—We observed that sensation of pain returned to the injected area about one hour after the operation was completed. Fifteen of the cases required a hypodermic injection of morphine, and two of these required one repetition of this drug. The other cases did not require it, as they complained only of slight discomfort.

Postoperative Vomiting.—This occurred in four of the cases, and but once in each instance. Furthermore it was noted that each of these received but a single dose of morphine for the postoperative pain. Since the vomiting followed the hypodermic injection within a very short time, we attribute it to the effect of the drug and not to the anesthetic. In the other nineteen cases even nausea was absent.

Postoperative Catheterization.—Although the patients were not previously taught to pass urine while in a recumbent position, nor were kept in bed for any length of time before operation, it is noteworthy that only three required catheterization, and two of these but once. The case that was catheterized four times during the first two days after operation was not operated under local analgesia exclusively, as general anesthesia was necessary for a thorough exploration of the abdomen because of the abnormal matted intestine which was found in the hernial sac. The general anesthetic was continued for the repair of the hernia of the other side. No doubt the general anesthesia and the added manipulations can well account for the retention of urine.

Postoperative Abdominal Distention.—Abdominal distention which usually follows general anesthesia was entirely absent in 70 per cent. of the cases in our series, and in the remaining 30 per cent. there was only a slight amount. None of the patients complained of abdominal discomfort.

Healing.—In twenty-two cases healing was by primary intention. The other case was drained down to the fascia because of the thickness of the fat of the subcutaneous tissue.

Appendicectomy Through the Herniotomy Wound.—In three of the cases removal of the appendix was accomplished through the inguinal incision. Only a slight amount of pain was experienced on tying off of the mesentery of the appendix. This can be eliminated if infiltration of the mesentery is employed.

ACID CRISES.*

By WALTON FOREST DUTTON, M.D.,

TULSA, OKLA.

The term acid when applied to the reaction of the secretions of the human organism and the idea that it is meant to convey have varied greatly during the course of years. The word was applied to certain obvious and apparently spontaneous changes in organic materials which are accompanied by substances showing a reddish discoloration with blue litmus and other indications of acidulous character. Acid sweats, changes in the constituents of the saliva, gastric juice, and urine, are conditions met with in diseased animal tissue.

These mysterious phenomena excited naturally the interest of investigators, and with the development of biochemical knowledge numerous other processes were discovered which resemble typical acids in that they seem to be due to specific agents whose mode of action differs from usual chemical reactions especially in the fact that the causative agent itself is not used up in the reaction.

On the basis of the considerations presented in the preceding paragraphs, I wish to present one phase of the subject which I shall call "Acid Crises."

Case I.—A housewife of thirty came under my service December 12, 1903, for the second time. At my first visit in July, 1903, a diagnosis of hysteria was made. Her attacks of illness were of similar character. There was sudden occurrence of pain, severe and cramp like. It always started in the right and left side of the back and flank, thnce radiating to the right and left inguinal regions. It would last from one to four days, and was relieved only by large doses of morphine. After relief there would be no recurrence for weeks or months. The pain was associated with nausea and vomiting. The urine was highly acid and scanty. Micturition was frequent and excruciatingly painful. The bowels were constipated, and acted every three or four days. Menstruation regular, but scanty and painful. She has had no children, no miscarriages; had rheumatism and typhoid fever in childhood. Vaginal discharges were distinctly acid and caused maceration of the mucous membrane. Tongue coated and very red—of the strawberry type. Morphine has been injected several times, and she has had morphine at intervening intervals.

In any patient who presents such a syndrome we naturally suspect a psychoneurosis, especially in a married woman who has had no children, but is passionately fond of them. Our data, however, point in another direction. The rheumatic history may have some bearing on the acid secretions. The

*Read before the Tulsa County Medical Society, February 9, 1915.

question remains, does this explain her present condition? The trouble may be due to acute infectious process or to functional derangements.

The slight elevation of or normal temperature, the normal blood count, and other negative physical conditions, must lead us to the conclusion that we are dealing with a functional disturbance.

The patient was given citrate of potassium, 20 grains three times a day, until the urine became alkaline. Later sodium bicarbonate, 10 grains three times daily. She was also advised to take sodium bicarbonate or potassium citrate for ten days every third month. She had had but two slight attacks in ten years.

Case II.—A mining engineer of twenty-seven came under my care August 20, 1904. His family history and habits were good. He states that he had gravel last May and several times previous, and since then has been well. His bowels act, on an average, once every two days. His appetite has remained good, and he has slept well. Beginning this morning he has had some severe pain in the region of the kidneys radiating to the groin, bladder, penis, and testicles. The pain is so excruciating that it requires a hypodermic injection of morphine to relieve it. The act of urination causes intense pain.

Physical examination was entirely negative except for the presence of intensely acid urine, scanty in amount, and of a specific gravity of 1024. *X*-ray examination of kidneys and bladder was negative. Cystoscopic examination revealed slight inflammation of the bladder, and spasmodic contraction of the ureters after the passage of each discharge of urine. The passage of the ureteral catheter was not possible on account of spasmodic contraction of ureters.

In the absence of fever, pyuria, calcium oxalate crystals, stone, or tumor, the usual group of kidney and bladder diseases, seemed here unlikely. We were much impressed with the close parallelism between the degree of acidity of secretions and the amount of acid present in the urine from day to day. Because of this parallelism it seemed wise to base treatment upon the idea that acid might be causing sufficient irritation to produce the line of symptoms by some means or other. Nevertheless, we felt by no means convinced that this hypothesis was correct, and looked forward with much interest to its confirmation or refutation through the outcome.

The patient was given a bland diet of which milk was the main article. Water was given in abundance. Sodium bicarbonate, 60 grains before meals, was administered. In a few days the acidity subsided. Patient was advised as to the procedure to pursue when the urine became highly acid. Ten years later there had been no return of the attacks.

Case III.—An unmarried woman, twenty-four years old, occupation typesetter, with an excellent family history, past history, and good habits, came under my service June 10, 1910. She had enjoyed good health until a year ago, when she had an attack similar to the present illness. She had had an attack about every two months since that time. The present illness came on suddenly with excruciating pain in the lumbar region reflected to the groin, bladder, and rectum. The act of micturition was very painful, frequent, and productive of only small amounts of urine. The urine was highly acid and caused extreme irritation of the vulvar mucous membrane. The secretions of the vagina were acid and irritating. Tongue red and coated, mucous membranes of mouth, pharynx, esophagus, and stomach sensitive to acid food. No elevation of temperature.

Under sodium bicarbonate, 30 grains thrice daily, the patient began to improve, and in a few days recovered. She was advised to take alkalies from time to time to keep the urine fairly normal and has had no recurrances of attack.

Case IV.—A stenographer of twenty-six, was first seen by me October 19, 1914. For several years she had periodic attacks which had been diagnosed appendicitis. Menstrual periods regular. Bowels constipated. Family history, past history, with exception of these attacks, and habits good.

Present illness began while she was seated at her work in the office. She felt faint and nauseated. She was taken home and a physician was called. She was found suffering with excruciating sharp, stabbing pains in the lumbar region radiating to the groin and bladder. She was unable to move without intense suffering.

On physical examination the pupils were seen to be equal and the reflex was normal. The chest showed nothing abnormal. Abdomen somewhat rigid and sensitive. Urine highly acid, specific gravity 1025. Vaginal secretions intensely acid. Tongue, coated and red. Kidney stone, Dietl's crisis, and other probable causes were excluded. My diagnosis was acid crisis.

The cases referred to above were selected from some 42 cases which have come under my observation in the last 12 years. They are very valuable from a diagnostic point of view, and no doubt will lead the way to clearer observation and deeper investigation in diseases not alone of the genitourinary tract, but of other secretory organs as well.

Our methods of investigating the abdomen, as compared with the other parts of the body, are rough and primitive. This, no doubt, accounts for so many grave errors in diagnosis.

The first few cases of acid crises are rather enigmatical to the tyro. After one has studied a few of these cases the diagnosis is comparatively easy. The symptom complex of one case is that of all with an occasional atypical case which is met with in all classified conditions.

Nephric, gastric, ureteral, and urethral crises, twisted mesentery, ureteral stone, appendicitis, kidney stone, and allied conditions are liable to be confounded with acid crises. The process of exclusion, or a thorough application of differential diagnosis, is absolutely necessary.

In the light of a more careful study of this condition, I have come to speak of these attacks as acid crises due mainly to the irritant but not due to any disease of the organ so affected. The intense excretion and secretion of the acid products by the organism reaches a high tide and is made manifest by the syndrome to which I have given the name, acid crises.

The cases are met with chiefly in persons of rheumatic, lithemic, or uremic diatheses. Persons who eat large quantities of meat or candy and small amounts of liquid are especially prone to this disorder. This disorder of metabolism is associated with retention of uric acid and other purin bodies in the system, characterized clinically by attacks of spasms of the pelvis of the kidney, ureters, bladder, and urethra, and due to irritation by a highly acid urine.

Crile maintains that acidity of the blood is increased by muscular effort, emotional disturbances, surgical shock, infections, asphyxia, inhalation anesthesia, and excision of the liver and kidneys. Ether, nitrous oxide, and alcohol produce acidity. A certain degree of acidity is incompatible with life. At the point of death the blood is always acid. He thinks that acidity is the actual cause of death. If epinephrin in sufficient quantity is injected, the acidity is controlled. Acidosis results from starvation, diabetes, and Bright's disease. The acidity of blood is increased two seconds after the beginning of nitrous oxide anesthesia. Acid inhibits the action of the cerebral cortex, but stimulates that of the medulla.

Crile intimates the influence of the chromaffin system, but does not elaborate on this theory. The intimate relationship of the internal secretions to any or all enzymes does not admit of discussion in this paper.

The purin bodies are related chemically and result from the transformation of the nucleoproteins of the food and of the tissues by enzymes, each one of which has its own specific action. Specific ferments also liberate trioxypurin or uric acid from the nucleoproteins of the tissues and from the purins of the food.

The accumulation of purin bodies in the system in considerable quantities is one of the essential etiological factors in acid crises. All mammals except man are able to rid the system rapidly of considerable quantities of uric acid. This is accomplished by a specific enzyme called uricase, which is present principally in the liver and kidneys. The inability of man to oxidize uric acid rapidly accounts for many morbid conditions and is due to this loss of uricolytic power. The loss of the power of the elimination and consequent concentration of purins, and the attempt on the part of the organism to get rid of these concentrated acid bodies are causative factors of acid crises.

The first essential in treating acid crises is proper regimen. Unless the patient obeys implicitly the injunctions regarding diet and mode of life in general from the first appearance of the disease, no really lasting benefit will be obtained from the treatment.

The fact that our theories as to the nature of various metabolic diseases are changing in the light of advanced knowledge leads us to assume a more lenient role in giving dietetic injunctions. We would advise that the amount should be limited, more especially in the case of those having high uric values.

Milk and eggs, fat and carbohydrates are to be given in limited amounts. A vegetable diet is to be encouraged. The most important beverage is water. It should be taken on an empty stomach and in large quantities. Milk, tea, coffee, lemonade, and light wines may be allowed in moderate amounts. Fruits are salutary and are to be very highly recommended.

An open air life with plenty of exercise, such as gymnastics, horseback riding, mountain climbing, gardening, and swimming, are imperative. In advanced cases baths such as may be taken at White Sulphur Springs, Bedford, and Saratoga Springs, in the United States; Weisbaden, Baden-Baden, Ems, Aix, and other springs of similar character in Europe.

The internal administration of alkalies is an efficient adjunct to the dietetic and hygienic advice above given. It has been proven beyond a reasonable doubt that alkalies prevent the accumulation of purin bodies in the tissues, and their value is enhanced by the employment of suitable mineral waters. These waters stimulate the conversion of nuclear material, increase activity of skin, lungs, and kidneys, benefit gastric intestinal catarrh, and overcome constipation.

A brisk calomel, soda, and podophyllin purge is always advantageous at the onset. Later, wine of colchicum combined with citrate of potassium, or carbonate of lithium may be administered. Aspirin, sodium bicarbonate, or piperazin may be given as an efficient aid in solution of uric acid. The severe paroxysms of pain often have to be controlled by large doses of morphine.

The acid crisis itself should always be the main object of our therapeutic efforts, and beyond this we may be guided by general principles.

PSYCHOGENIC CONVULSIONS.

THE RESULT OF A WISH.*

By THADDEUS HOYT AMES, M.D.,

Assistant Physician in Outdoor Department, Neurological Institute; Assistant Attending Neurologist, City Hospital; Clinical Instructor in Neurology, Cornell Medical School,

AND

RUSSELL MACROBERT, M.D.,

Resident Physician, Neurological Institute, New York.

A girl, aged 18, entered the Neurological Institute on the service of Dr. Frederick Peterson the first of November, 1914, with a history of left-sided convulsions, occurring at varying intervals over a period of four years.

She was the seventh of nine children, five of whom died in infancy. There was no history of epilepsy in the family. With the exception of an illness at the age of 8, diagnosed as spinal meningitis, the patient's health had always been good.

Her present trouble started with a convulsive attack in August, 1910, and since then attacks have occurred at irregular hours and at varying intervals. During the past year they were as frequent as once a month, but there were times when the interval was only three days. They came on when she was lying down, sitting, or standing; there was no prodromal warning of the attacks. She was always conscious during the attacks, but could not interrupt them. After they subsided she felt weak for a few hours or even for days, but did not have stupor or headache. Physicians gave her constant care during the past four years, using various forms of treatment; for the past nine months she was treated thoroughly with bromide. When she came to the Institute she thought there was a possibility of an operation.

On admission the physical examination showed no abnormality. The reflexes were equal on the two sides, and were all rather lively. Her eyegrounds were found by Dr. Holden, the consultant oculist to the Institute, to be normal. The Wassermann, urine and routine blood examinations were negative. From the nature of her history and her examination, Dr. Peterson considered the attacks to be of a functional character.

Three days after her admission this unilateral convulsion started without warning or provocation. It was violent for 40 minutes, and persisted to a lesser degree for 36 hours. She was perfectly conscious and lay turned toward the right side, the left leg and left arm jerking in vigorous, irregular clonic spasms. The right side was disturbed only by the violence of the movements of the other side. In each spasm the left arm was extended fully, a little posterior to the hips; the hand was over pronated, the palm outward and the back of the hand toward her. Each tense thrust carried the hand backward nearly a foot from her. The left leg muscles during the spasms carried the knee upward and across the abdomen to the right side. Each one of the series of spasms constituting this attack consisted of a synchronous pushing of the hand away from the body and a drawing of the knee toward the abdomen across the midline of the body. There was no biting of the tongue, nor incontinence, nor frothing at the mouth.

During the entire convulsion she answered questions and complied with all requests. She said she

*Read before the Neurological Section of the New York Academy of Medicine, in December, 1914.

was suffering, and asked that something be done to relieve her. There was every evidence that she was uncomfortable and that she was getting no pleasure from the performance.

During this attack the pupils responded promptly to light and accommodation; the knee jerks and ankle jerks and plantar reflexes were all normal, the right equalling the left; there was no Babinski nor Oppenheim; nor was there lessening of the stereognostic sense in the convulsed hand. The tongue protruded in the midline. There was no mental confusion. There was no restriction of visual fields. Her corneal and pharyngeal reflexes were present. There was no generalized nor local cutaneous anaesthesia, nor any of the usual stigmata of hysteria. Patient was shown in the convulsion at the weekly conference of physicians at the Neurological Institute, and all present agreed that this was a functional disorder. The attack, which was witnessed also by Dr. Peterson, confirmed his previous opinion as to its functional character, and he decided that the causative psychic influences should be ascertained.

Assuming at the outset that all functional attacks express in some way a repressed wish and bring about something for the patient which cannot otherwise be accomplished, inquiries were commenced into the girl's mental processes.

Although she was 18, her intelligence was not that of a girl of that age; it was found by the Binet-Simon test to be that of a girl of only 12. She stopped school at the age of 14, never had any close friends, and was not in the habit of expressing her thoughts. She displayed great reluctance in speaking of even the most trivial affairs at home, but was persuaded to talk about the things that worried her.

She worried most, she said, in regard to the future in store for her. When her attacks began four years ago, as it was feared that she would have them in some public place, she dropped out of all school, church, and social relationships. The doctors advised her against severe exertion; so her daily life consisted of the lighter household duties, reading, sewing, and having her friends visit her. Her friends did not come in very often; sewing was the only amusement she enjoyed; reading did not appeal to her at all; card playing and dancing were not approved of by the family; such duties as washing dishes, making beds, and feeding chickens were intensely disagreeable to her, and she considered herself to be very unhappy, and frequently thought she would rather be dead than live having continued attacks.

Another thing that bothered her a great deal was the objection of her two oldest sisters to the marriage of another sister, aged 21, to a certain man of whom the patient approved. The circumstances did not require her intervention, she knew, because this sister was able to manage her own love affairs, but she could not keep from worrying about the matter. The girl was upset emotionally when she mentioned this sister's trouble, so much more than the occasion warranted that it seemed there must be some other reason than this excuse which spurred her into action in this instance. Another worry was her inability to control her temper—little things irritated her to such an extent that for many years she was in the habit of flying into a rage and throwing things on the floor. She said she often prayed that she might be able to control her temper.

On being questioned in regard to other worries or habits the patient burst out with her real secret. She did not appear to be ashamed of it, but asserted that the fault was not hers, a habit having been shown her by this sister, on whom she shifted the entire blame. She recalled that it began when she was 10 years of age, and her sister 13. It was a mutual masturbation which occurred only at night; they always slept together, never interchanging sides in the bed; the sister was always on the left of the patient. There was a strict and tacit understanding between the sisters that no mention ever be made of these performances. They indicated their intentions, not by spoken words but by their actions, and when the patient felt too tired and sleepy to participate, she did not indicate her unwillingness by words, but, turning over on her right side, she pushed her sister's hand away and drew up her knee to protect herself. When the sister persisted, it required repeated pushes with the patient's left arm and movements with her leg to stop her. The patient gradually came to feel that the whole performance was wrong, and her remonstrances became more and more frequent until this mutual practice ceased.

However, the desire for the sensation could not be resisted by the girl, and she kept up the practice herself. There were times when she felt distressed about it, but as she thought she would never have learned the habit herself, at these times she blamed her sister. She never referred to what was in her mind, but, instead, frequently quarreled with the sister over trivial matters.

When she was 14, during the summer, she was more openly antagonistic toward this sister, and on one occasion when she was irritable the sister was waiting for her to get ready for a church concert and she deliberately took a longer time than was necessary. The sister teased and nagged her to hurry but, as there was company in the house, she did not lose her temper at the time, although inwardly more angry than ever before. After arriving at the concert she suddenly began to tremble and was taken out into the vestibule of the church. She recalled in telling the story her very definite impression of this sister, who happened to be standing just to her left. The whole accumulation of anger against her for having taught the habit, surged up in a violent emotion, which seemed to draw her away from the sister with a feeling of revulsion, and movements for protection commenced in her left side and became uncontrollable. This was in August, 1910, and constituted the first attack.

The patient had such a keen recollection of all the details of the story she had been telling that she could show the movements she described; so she was asked to reproduce the whole scene of her first attack. She did this. She then, at request, showed the movements of her other attacks in the sitting, standing, and lying-down positions. She declared that these were all alike and identical with the first attack. On being asked to show, first, a single isolated movement of an attack, and then the movement used in restraining the sister, she complied, and immediately saw and declared that these were absolutely identical. She was then asked to demonstrate how she repelled her sister's repeated persistent advances. She did this by a series of the single movements which, when reproduced, constituted an exact counterpart of an attack. The analogy was at once so manifest to her

that she exclaimed, "Why, these movements are all the same."

If then the movements of these attacks were the same as those of her early revolt against the mutual practice, there seemed to be a reason for inferring that these recent attacks in their way, too, were a revolt—that they were representative of some other struggle against something she wanted to stop. On being asked what it was, she instantly replied it was this habit. It was a habit she knew she should stop, and yet sometimes one she wished she could continue, and although the sensation was one she could not always resist, she always felt that she needed some justification for it to her own conscience. This justification came by arguing that as she did not learn the habit herself, but was shown it, the fault was not hers and the blame was all on her sister. With the moral responsibility thus shifted her conscience was appeased. Nevertheless, as time went on she gradually felt just as she had felt years before when she broke off the first habit, that this one, too, should be stopped. That was her state of mind before the attacks began; these were the conditions which made a readjustment necessary.

The patient was then asked to recall the identity she had just admitted between the movements of the attacks and those of the revolt against her first habit and to consider if they had any relation to the habit with which she was at present struggling. She said that because she had believed her sister responsible for the habit she supposed that the same movements which warded off her sister the first time expressed her feelings in this instance. The patient had never before considered that these attacks were anything other than very distressing, but she readily realized at this stage of the analysis that they were the result of a distinct wish; they were an expression of her revolt, but did not stop the habit; unintentionally and unconsciously they did exactly what she wanted. The attacks were the outward form of her desire to be relieved of responsibility for the occurrence of the habit which she enjoyed, but which her conscience did not sanction.

She was now persuaded that she was solely responsible for the continuance of the habit in the future, and that she should no longer have attacks which only implied blame to her sister, and did nothing toward stopping the habit. She promised to assume the entire responsibility herself for any indulgence in the future, and not to have any more attacks. Up to date of the publishing of this article she has kept her promise.

Thanks are hereby expressed to Dr. Peterson for his permission to present this case and for his assistance in the preparation of this paper.

HUMANIZED MILK IN INFANT FEEDING.

By J. EPSTEIN, M.D.,

NEW YORK.

CLINICAL ASSISTANT IN MEDICINE, VANDERBILT CLINIC; IN PEDIATRICS, MOUNT SINAI HOSPITAL DISPENSARY AND BABIES' HOSPITAL DISPENSARY.

THAT mother's milk is the best food for her infant is past all discussion. When the supply of mother's milk is inadequate to feed her infant, complementary feeding with modified cow's milk becomes necessary. The feeding from the breast and bottle should be either alternately or to suit the convenience of the mother. Were every mother to nurse her infant, pediatrics would lose a great deal of its importance and usefulness. But since many mothers do not nurse their infants at all, there has developed a special science of infant feeding.

Though cow's milk is the only food used in the artificial feeding of infants and its constituent elements are very few, still there is no standard of infant feeding or milk modification. There are very able pediatrists who prescribe high fat and equally able pediatrists who advise low fat. The proteins are blamed by some for all ills, while others consider them entirely harmless. The sugar has not escaped the same fate and the salts are under suspicion.

Though every pediatrist claims the best results with his particular method of feeding, yet for practical purposes it would be very desirable to have some standard or basis for infant feeding from which the physician might deviate at times to meet certain special cases, but there should be a general diet for all healthy infants as there is a general diet for all healthy adults. The sick infant should be studied individually as to its digestive ability and fed accordingly, but the majority of healthy infants are almost alike and could be fed on a uniform diet.

Artificial infant feeding may be divided into three classes: (1) The feeding of healthy infants; (2) The feeding of infants during acute illness; (3) The feeding of infants suffering from some chronic gastrointestinal disease, or poor digestive ability, or intolerance for certain elements in the milk.

In order to feed the average healthy infant there are at present two methods which are commonly used: (1) Simple dilution of whole milk; (2) Percentage feeding.

Simple dilution of whole milk is really simple and at times very useful, but babies do not thrive on simplicity alone. Comparing the food value of this simple milk modification with the food value the baby would have received from the breast, especially in the early months of infancy, the infant is cheated of its food at the threshold of life. Percentage feeding is scientific and a proper food can be prepared by this exact method, but the majority of physicians know very little about it. The result is that many infants, healthy at birth, are made hopelessly ill by all kinds of irrational milk modifications.

Humanized milk—that is, cow's milk with the percentage composition of human milk—can be given to the vast army of healthy babies from early infancy to the end of the first year. It has a scientific basis for its use and infants fed on this food show a steady gain in every way.

In order to make it available to the average mother or nurse, I have much simplified the method of its preparation. The food is prepared from the upper 15 ounces of a quart bottle of milk.

The upper 15 ounces of a quart bottle of milk after standing undisturbed for six hours at a temperature of from 40° to 50° F. has approximately the following percentage composition: Protein, 3.40; sugar, 4.50; fat, 8.00; salts, 0.70; water, 83.40.

When this upper 15 ounces is diluted with an equal volume of water it gives the following percentage composition: Protein, 1.70; sugar, 2.25; fat, 4.00; salts, 0.35; water, 91.70.

On adding sugar to this milk to make up 7 per cent. it has the following composition: Protein, 1.70; sugar, 7.00; fat, 4.00; salts, 0.35; water 86.95.

From the above it is evident that by this simple

process of diluting once the upper 15 ounces of a quart bottle of milk we obtain a food that is very near to human milk.

HUMAN MILK.		HUMANIZED MILK.	
Protein	1.50	Protein	1.70
Sugar	7.00	Sugar	7.00
Fat	4.00	Fat	4.00
Salts	0.20	Salts	0.35
Water	87.30	Water	86.95

Having decided by the weight, age, and general condition of the infant how many ounces of food it requires at each feeding and the number of feedings in 24 hours, the mother or nurse is directed to use the upper 15 ounces of one or two quart bottles of certified raw milk and out of these 15 or 30 ounces of milk she takes as many ounces as she is directed, and to this she adds an equal number of ounces of cooled boiled water, to which the proper amount of milk sugar has been previously added. The entire quantity of food which is made up of half milk, half water, and sugar is now equally divided into the number of feedings required and fed at regular hours.

The feeding of infants during acute illness or of those suffering from chronic digestive disturbances or intolerance for certain elements in the milk requires individual study to adapt the food to the baby's condition.

Humanized milk is not intended to replace human milk, though it approximates it very closely in the percentage of solids, there still remain the chemical and biological differences which cannot be changed by any known means. Neither is humanized milk suggested to replace entirely the more scientific and exact method of fitting the food to each individual baby which is the aim of the pediatrist. But it is recommended as a very useful food for the average healthy infant who is under the care of the busy, practical general practitioner of medicine whose daily work among his little patients offers great opportunities to do much good.

1450 Lexington Avenue.

Medicolegal Notes.

"Culpable Negligence" of Physician or Surgeon.—A medical man demurred to an indictment accusing him of the offense of manslaughter in the second degree, on the ground that the acts or omissions charged were not stated with sufficiently certainty to, and did not constitute, a public offense. The demurrer being overruled, the case was certified to the Minnesota Supreme Court. The indictment was found under the Minnesota statute of 1913, declaring manslaughter to be of this degree when committed without any design to effect death, "by any act, procurement, or culpable negligence" not constituting a higher crime. It alleged that the defendant, without authority of law, but without a design to effect her death, did feloniously employ on the body of one R. N., an *x*-ray machine for the purpose of taking an *x*-ray picture of her hip, for his sole use and purpose, with her consent, extracted on his assurance that the exposure to the *x*-ray would do her no harm; and that he "did then and there turn and apply said *x*-ray upon the body of the said R. N. in and over the regions of her right hip, the said machine being a dangerous instrument, except when operated by a skillful manager it was not necessarily dangerous, which danger the said C. A. L. knew, or, in the exercise of the care required under the circumstances, he should have known, and said C. A. L. did then and there place the tube of the said *x*-ray unreasonably close to the body of her, the said R. N., and, disregarding the duty he owed her, he did negligently and carelessly fail to give her, during the time of such exposure to such *x*-ray as aforesaid, such proper and requisite attention as was requisite and proper to prevent burning her, and did operate such *x*-ray in an unskillful manner, and did keep her body so exposed for an unreasonable length of time, thereby inflicting upon the body of her, the said R. N., in the region of the right hip, as aforesaid, a mortal burn and injury known as an *x*-ray burn, from which mortal burn so caused as aforesaid, she, the said R. N., died."

In sustaining the order overruling the demurrer, the Supreme Court said that culpable negligence—that is, criminal negligence—is largely a matter of degree, and is incapable of precise definition. Whether it exists to such a degree as to involve criminal liability is a question that must be left, to a great extent, to the common sense of the jury. But not every careless or negligent act whereby death ensues comes within the statute, and something more must appear than the essentials necessary to impose civil liability for damages. When considered as the basis of a charge of manslaughter against a medical man, or person assuming to act as such, culpable negligence exists where he exhibits gross lack of competency or inattention, or wanton indifference to the patient's safety, which may arise from his gross ignorance of the science or through gross negligence in either its application or lack of proper skill in the use of instruments. Where, however, he does nothing that an ordinarily skilled and careful practitioner might not do, and death results merely from an error of judgment or accident, no criminal liability attaches. "Gross," as the court used the word, was intended to convey the idea of recklessness with regard to the safety of others, or "foolhardy presumption," as expressed by Mr. Justice Holmes, in Corn. v. Pierce, 138 Mass. 165. The failure to allege knowledge on the defendant's part that his acts involved probability of serious consequences to the deceased was not fatal to the indictment; the defect, if any, in that regard, being cured by the prsumption of contemplation of probable consequences. Nor was it necessary to allege the defendant's duty to the deceased under the circumstances, nor to set up a specific standard by which his acts might be measured; these being matters of law. —State v. Lester, Minnesota Supreme Court, 149 N. W. 297.

Employer's Liability for Medical Services.—A mill company had an arrangement with a hospital association to render medical treatment to injured employees in consideration of a deduction from their pay. An employee, H., having suffered a severe injury, the defendant directed another employee to take him to the hospital, which he did. On the way they were met by H.'s uncle, who, on arriving at the hospital, discharged the surgeon employed by the association and requested that the plaintiff, his family physician, treat the case. H. died, after which the uncle told the employee who took H. to the hospital, and who was merely a lumber salesman for the mill company, that there were certain physician's and nurse's charges, which the salesman said the company would pay. In an action by the physician against the company for his services, it was held that the defendant's obligation arising from its agreement to furnish medical attention was discharged when it sent H. to the hospital, and provided a competent surgeon to treat him, and, the salesman's promise to pay the plaintiff's bill not being within the scope of his authority, the defendant was not liable. The rule that an employer is bound to furnish medical attention to an injured employee in case of extreme urgency calling for immediate action did not apply for two reasons: (a) The defendant had already made reasonable provision for medical and surgical attention and hospital care; (b) the defendant's place of business was near Seattle, had telephonic communication with it, and its representative officers could readily have been communicated with.—Vanderboget v. Campbell Mill Co., Washington Supreme Court, 144 Pac. 905.

Opinion Evidence as to Sanity.—The Illinois Supreme Court holds that where an accused sets up the defense of insanity, a physician who examined him several months after the commission of the crime is competent to give opinion evidence on the question whether he was insane at the time of the crime.—People v. Gavrilovich, 265 Ill. 11.

Privileged Communications.—In an action for personal injuries it was held that the testimony of physicians who made an examination of the plaintiff, a section foreman, to ascertain his physical ability to work on the railroad, was not privileged, their information not being obtained for the purpose of treating or acting for him.—Cherpeski v. Great Northern Ry. Co., Minnesota Supreme Court, 150 N. W. 1091.

THE ETIOLOGY OF RICKETS.

In spite of the fact that this disease has been studied for the past three hundred years the knowledge of its etiology is still extremely indefinite. This is not because there has been lacking an abundance of material for its study, for it is one of the most common of the diseases of infancy. According to Still 44.6 per cent. of London children brought to the hospital for various diseases show signs of rickets. The tendency has been to ascribe this disease either to errors of nutrition or to a vicious environment. Most English and American pediatrists perceive the cause in a defective diet, chiefly in a deficiency of fat. Marfan attributes rickets to an intestinal autointoxication; von Hansemann to "domestication"; Mousser and Koch to an infection, and others, most recently Klose and Vogt and Stoeltzner, to a defect in the internal secretions, chiefly to a deficiency in the thymus gland.

The relative frequency of rachitis in large cities and among the poorer classes has given rise to the hypothesis that this disease is the result of overcrowding. Leonard Findlay (*Lancet*, May 8, 1915) has investigated this phase of the subject, basing this study upon careful observation of the home conditions of from 400 to 500 rachitic children in the city of Glasgow. He cites the results of an experimental investigation that he had made a number of years ago in which he showed that the disease could be induced in animals by confinement. In fact, rickets is extremely common in zoological gardens. The lack of exercise under normal conditions of life apparently prevents the retention of a sufficient amount of calcium by the organism, as recently demonstrated experimentally by Kochmann and Petzsch.

In pursuing his statistical study Findlay investigated the possible rôle of the following factors: (1) the length of time the child was breast-fed; (2) the order of the child in the family; (3) the condition of the bowels previous to the onset of the trouble; (4) the amount of air space in the house allowed to the child; (5) the number of stairs to be mounted to reach the house, and finally (6) whether or not the child has been taken much out of doors. As regards the influence of artificial versus breast feeding it was found that rickets developed just as frequently among the breast-fed as among the bottle-fed, and that the disease could not be attributed to prolonged suckling. Nor was there any evidence of a tendency to intestinal troubles in the rachitic infants prior to the development of the disease. This appeared to attack more frequently the earlier than the later members of a family.

Housing conditions seemed to be intimately associated with the cases of rickets. This was more common in infants living in the uppermost floors of tenement houses, with which circumstance was probably connected the fact that these children were not taken out in the fresh air as much as those living nearer or on the ground floor. Of still greater significance were the figures obtained by Findlay with reference to the size of the home and the number of individuals in the family; in other words, with reference to the amount of air space allowed to each child. It was found that the incidence of rickets is definitely proportionate to this amount. The explanation is made that this factor probably acts in a twofold manner: the lack of fresh air making the infant less inclined for exercise and the overcrowded home preventing the child from being properly attended to by the mother.

In seeking to place a proper valuation upon the statistics obtained by Findlay one must not be unmindful of the fact that these figures may be interpreted in different ways, according to the preconceived notions and convictions of the observer. Overcrowding goes hand in hand with abject conditions of life—with the entire train of ailments resulting from poverty and neglect. These bring one again to the question of feeding, which, after all, in view of the every-day experience of most observers and the happy results of a proper dietetic therapy in this disease, seems to be the fundamental problem in rickets.

TYPHUS FEVER.

Now that typhus fever is raging in Serbia and Montenegro, and probably to a greater or lesser extent throughout the battlegrounds of Eastern Europe, revived but melancholy interest is taken in this supposedly almost extinct disease. Dr. John F. Anderson, Director of the Hygienic Laboratory, U. S. Public Health Service, writes in *Public Health Reports*, April 30, 1915, concerning the etiology and prevention of this deadly pest. The author gives a sketch of the work done by various investigators in this field, including that by Dr. Goldberger and himself.

Attention is drawn to the now accepted fact that the body louse is the means by which typhus fever is transmitted. The clinical differences between typhus and typhoid are described, a point of special significance to the clinician. As a rule, the onset of typhus is more abrupt than that of typhoid fever. Chilliness or a distinct chill is common at the onset of typhus, very much more so than in typhoid. Headache with or without chilliness and with or without malaise almost invariably marks the invasion of typhus. In marked contrast to typhoid, the face is flushed and the conjunctivæ are congested in the first few days as the result of a capillary congestion not unlike that seen at the outset of dengue or of yellow fever.

The temperature rises rapidly and with it the pulse rate. In typhoid both rise more slowly. The fever of typhus does not, as a rule, range at high levels. In this as well as in some features of its outset typhus strikingly resembles yellow fever. The duration of the fever is about twice that of yellow fever and about half that of typhoid. An important distinction relates to the eruption. The eruption of typhus appears within three to five days after the onset, therefore earlier than is the rule in typhoid; it is general, sparing only palms and soles; its evolution is rapid, being fully out within 24 to 36 hours, and is permanent, in marked contrast to the typhoid eruption which appears in successive crops. It is important also to recall that the macules constituting the typhus eruption are polymorphic. They have not the regularity of outline or the uniformity of size and appearance of the typhoid rose-spots. Moreover, while most or all of the lesions may fade markedly on pressure in the early stages, some fade little if at all, and the proportion of these may and usually does rapidly increase, the eruption becoming petechial as it becomes older.

According to Anderson the body louse is the only agency through which the disease is spread and therefore all efforts at prevention are centered upon this parasite, and these efforts may be broadly grouped under the following headings: (1) Measures for the reduction of lice infestation among the population in general. (2) The destruction of all lice and their eggs found on the bodies, clothing, bedding, and surroundings of all cases of typhus, typhus suspects, and contacts. (3) The adoption of measures by persons in the vicinity of cases of typhus, to reduce or prevent the possibility of their being bitten by lice. (4) Inoculation with the mild type of the disease, Brill's disease, by persons contemplating entering localities where the disease is prevalent. Should Plotz's work be confirmed the use of a vaccine prepared from the typhus fever germ may be substituted for this.

Typhus fever is essentially a war disease, or, rather, it might be said that war furnishes those conditions which favor its inception and spread. It is very difficult, among soldiers who, like the Serbians, through the exigencies of warfare are compelled to live in dirty surroundings and who are unable to change their clothes or take baths to keep the body free from lice. When, however, it is clearly understood that the louse is the main, if not the only factor in disseminating the infection, and strong measures are put into force to destroy these insects, then the spread of typhus will be stayed. If, too, the vaccine discovered by Plotz is found to be effectual in rendering persons immune or more or less immune to the infection then another powerful weapon to be used against the disease will have been forged. The treatment of typhus fever presents no novel or especial features, and the hopes for its extinction or partial suppression rest wholly on preventive methods. The results of the work done by the American Commission now in Serbia will be followed with great interest here, as it is a practical attempt on a large scale to solve the problem of how to extinguish typhus fever.

PREPARATION OF THE AMERICAN PROFESSION FOR WAR.

With the war clouds rising so ominously out of the sea it is the duty of every American physician to take thought how he can best serve his country in the deplorable case that hostilities become unavoidable. No matter how strictly men of our profession observe neutrality or how strongly they would deprecate a war, knowing as they must something of the suffering attendant upon wounds, exposure, traumatism, etc., things which the layman may not appreciate, it is their patriotic duty as well as their obligation to the cause of humanitarianism which they have made their life work to be prepared to bear their share of the burden in case their country is forced into the present European war. Should this happen, there is no doubt that every man in the profession would be affected somewhat. Those physicians already in the various branches of the service would, of course, have their duties marked out for them from the first. The members of the Medical Reserve Corps should expect and be prepared for calls to service. Younger members of the profession, recent graduates perhaps, who have not yet located permanently nor given hostages to fortune should be prepared to offer their services to their country. Some of the older physicians who have none dependent on them or whose families are in easy circumstances, should be ready to volunteer. Other practising physicians who would find it impossible to give up their work can do their part by volunteering to assume the practices of their colleagues who have answered their country's call during the course of the war.

In these and other ways can the members of our profession make ready, not in any spirit of belligerency or in any desire to precipitate a war, but in the realization of a grave national crisis. It resolves itself for each physician into a question as to whether or not he would be able to give his services to his country in case of war. If he decides that for any reason he cannot undertake military service he should be prepared to assist in every way those who can go.

Having once made up his mind that he can volunteer, however, the physician should not be content to let the matter rest there. There are many ways in which he can make himself of greater value to his country. His personal affairs, of course, should be gotten in such shape that he can leave at a moment's notice. A review of surgery would, in the case of the average practitioner, be beneficial, especially military surgery, gunshot wounds, amputations, etc. The foreign medical journals nowadays will be found full of articles pertinent to war and the physician who contemplates volunteering would do well to read these, or at least the abstracts of them appearing in the medical journals here. It would not even be amiss for the prospective medical officer to familiarize himself to some extent with the drill regulations, especially the formation, the evolutions, and the manual of the litter. If our readers think that this is of minor importance, a talk with any medical officer of the regular army will undeceive them.

CARE OF THE MENTALLY DISEASED AND MENTALLY DEFECTIVE.

At a recent meeting of the New York Psychiatrical Society the following resolutions were adopted:

"I. That this society recommend (1) that the State Constitution require the Legislature to provide for a State Hospital Commission, the president of which shall be a physician who is specially qualified in mental diseases and in institutional administration, and for a State Commission on Mental Deficiency, the president of which shall be a physician who is specially qualified in mental deficiency and in institutional administration; (2) that the State Hospital Commission be given power not only to visit and inspect all institutions either public or private, used for the care and treatment of persons suffering from mental diseases, as at present, but be also given fiscal control of the State institutions for the care and treatment of such persons, and general supervision of their administration by the boards of managers; (3) that the State Commission on Mental Deficiency be given equal powers to those of the State Hospital Commission in regard to the institutions for the care and treatment of persons suffering from mental deficiency.

"II. That this society believes that a system of fiscal control of the State institutions for the mentally diseased and mentally defective by a board of control which would be independent of the specially qualified commissioners recommended in the preceding resolutions would be inefficient and would be detrimental to the proper treatment of the patients and to the interests of the State in dealing with the important problems of mental disease and deficiency."

As stated in the preamble to these resolutions, the essentials of an efficient and stable State system for the care of sufferers from mental diseases and mental defects should, as experience has amply shown, be safeguarded and shaped by constitutional requirements, and furthermore no system can be efficient unless it is administered by specially qualified officials. As the framers of the new State constitution, now in convention, must necessarily look to experts for advice as to the proper way of dealing with special subjects, we hope and feel sure they will give earnest consideration to the recommendations of the Psychiatrical Society. The members of this society are all specialists in nervous and mental diseases and have expert knowledge concerning the treatment of the mentally diseased, being particularly well informed and actively interested in the State asylums for the care of the insane and feebleminded. They are therefore preeminently qualified to advise the Constitutional Convention on such matters.

Hygiene at the Panama Exposition.

Every effort is being made to conserve the health of the employees of the Panama-Pacific International Exposition and to render the grounds and buildings healthful. Surgeon C. C. Pierce of the United States Public Health Service is in charge of the sanitary supervision of the exposition, and he relates in *Public Health Reports*, April 16, 1915, the steps that have been taken to safeguard the health of those working on the buildings and grounds and of visitors. These sanitary precautions appear to be thorough, and consequently those who intend to visit the San Francisco exposition during the coming summer need have no qualms as to its salubrity. The exhibits of hygiene at the exposition are full and diverse. They are scientifically accurate and are arranged in as graphic and interesting a manner as possible and on a plane readily comprehensible by the general public. The chief hygienic exhibits will be social—on sex hygiene, the tuberculosis problem, hookwoorm disease, personal hygiene with special reference to the harmful and fraudulent character of patent medicine now on the market, mouth hygiene, alcohol and other habit-forming drugs, mental hygiene, psychiatry and the care and treatment of the insane, feeblemindedness, school hygiene, filtration and sewage disposal, tropical medicine and hygiene, infant hygiene, eugenics, military hygiene, and the mode of spread of infectious diseases. From a perusal of the above it will be evident that the hygienic display, as shown in the exhibit of the U. S. Public Health Service, cannot fail to be in the highest degree instructive and interesting.

The Uric Acid of the Blood.

An important part of the studies which have been carried out in diseases of metabolism, especially gout, has been the estimation of the amount of uric acid in the blood. Numerous methods have been tried, and only that devised by Folin has been adjudged reliable. Now, however, new evidence has been presented, and as a result all the former work must be swept into the discard and the problem must be attacked from the beginning. Benedict (*Jour. Biol. Chem.*, 1915, xx, 633) has pointed out defects in the Folin method and has presented a modification. But what is of the greatest importance he has shown that the uric acid exists in blood in two forms, a "free" and a "combined." Thus ox blood which was believed to contain 0.2 mgm. per 100 c.c. was found as a rule to contain about 7. mgm. of total uric acid per 100 c.c. of blood, and, moreover, it was contained practically in its entirety in the red blood cells. Chicken blood, on the other hand, showed practically none of the combined uric acid, the free acid present being contained only in the serum, none of it being in the corpuscles. If the ox blood were allowed to stand at room temperature and protected from bacterial contamination there was found to take place a gradual transition from the combined to the free form of uric acid, apparently due to the action of some ferment. Just what the result of these observations will be cannot, of course, at this time be safely predicted. It is obvious, however, that all of the work on the uric acid content of the blood will have to be repeated. Numerous hypotheses will at once suggest themselves. Benedict suggests that possibly the free uric acid is that which is ready for excretion as such, while the combined is capable of further catabolism. The state in which the uric acid exists in the red cells is another interesting question. It is discouraging in a way to think of the amount of work which has been done to no purpose, but it is highly encouraging to know that a definite step forward has been made.

Diathermy at the Front.

At a Military Medical Evening Session held at Siemensstadt, March 16 (*Berliner klinische Wochenschrift*, March 29), Bucky praised the unexpected results of diathermy in nerve lesions. Either the direct or alternating current causes a marked stimulation of muscle or nerve tissue, the intensity being very low. The current changes the conductor, in the case of animal tissues, into a conductor of the second order—an electrolyte. As a result of the currents there occurs an ionic migration between the poles. If the alternating current is introduced at this point, with a frequency of 100 alternations per second, the number of alternations may be increased to one million—an inconceivable frequency, which has no stimulating properties and no ionic dissociation. Diathermy is therefore without stimulating properties, although a bulb introduced into the circuit glows brightly. If this current is passed through resistance, heat is generated. The current applied to injured tissues in warfare showed a beneficial reaction not only in tissues without lesion of the nerves, but in nerve traumatisms. The beneficent effects were, of course, due to thermotherapy. Bucky claims that this diathermy is a successful competitor of hot-air therapy.

News of the Week.

Warning.—Subscribers to William Wood & Company's publications are warned not to pay any money to the "National Educational Association, No. 130 Nassau street, New ork City," or to any persons representing this association, as they are not authorized to collect money or solicit subscriptions for any of the publications of William Wood & Company.

Committee of American Physicians for the Relief of the Belgium Profession.—The following extract from a letter by Dr. George W. Crile of Cleveland shows the great and continuing need of our colleagues in Belgium: "When I was in Belgium I received first-hand information from a number of Belgian physicians concerning their plight. They are indeed in dire need and there seems to be no way by which this need can be overcome until their land is restored to them again. The freemasonry of the medical profession so binds all medical men together that it seems to me that no appeal to doctors for the aid of their associates in Belgium can be in vain. We should all realize also that no single appeal can satisfy what is going to be a long-continued need, that we must give now, later again, and still later, and so answer repeated appeals until later conditions may restore to the Belgians the wherewithal to aid themselves."

Dr. F. F. Simpson, treasurer, 7048 Jenkins Arcade Building, Pittsburgh, reports the following contributions received during the week ending May 22:

Dr. H. M. Manning, P. A. Surgeon, U. S. P. H. S., Charleston, S. C.	$5.00
Anonymous—K., Toledo, Ohio	5.00
Dr. Dwight G. Kreul, Davenport, Iowa	10.00
M. L. H., Wallum Lake, R. I.	3.00
Knox Co. Medical Society, Fredericktown, Ohio	10.00
The Medical Club of Portland, Portland, Oregon	25.00
Dr. Edward E. Bancroft, Wellesley, Mass.	10.00
Dr. Thomas St. Clair, Latrobe, Pa.	5.00
Dr. Fred T. Murphy, St. Louis, Mo.	50.00
Dr. Hermann Grad, New York, N. Y.	10.00
Receipts for the week ending May 22	$133.00
Previously reported receipts	6,860.50
Total receipts	$6,993.50

Disbursements for the week ending May 22, 178 standard boxes of food at $2.28	$405.84
Previously reported disbursements: 1,625 standard boxes of food, at $2.20	3,575.00
1,309 standard boxes of food, at $2.30	3,010.70
Total disbursements	6,991.54
Balance	$1.96

In Memory of Madame Depage.—We understand that there is a movement on foot among English surgeons to establish a permanent memorial to Mme. Depage of Brussels, who was killed in the *Lusitania* outrage while on her way home with money collected in this country for the Red Cross. If steps are definitely taken for the memorial the many friends in America of Dr. Depage will no doubt claim the privilege of taking part in this tribute to the memory of a noble and greatly beloved woman.

Gorgas Prize Medal.—This is to be awarded yearly by the Association of the Medical Reserve Corps, U. S. Army, New York State Division. The competition is open to medical officers of the army, officers of the Medical Reserve Corps of the Army, and medical officers of the organized militia. The medal will be awarded for the paper submitted which shows the most important advance in medicine or surgery on a medical or medico-military subject, preference being given to the latter. The papers should be submitted by March 31 of each year, and should be addressed to the president of the Board of Award, Gorgas Prize Medal, Army Medical School, Washington, D. C. The award will be announced at the graduation exercises of the Army Medical School, on May 31 of each year.

Hospital for Drug Victims.—A fund of $6,000 has been subscribed by a number of women whose names are not published, for the purpose of building a hospital for the care and treatment of sufferers from the drug habit. The money was recently turned over to Dr. Katharine B. Davis, Commissioner of the Department of Correction, who accepted it in behalf of the city. The hospital is to be built on Riker's Island, where a municipal farm is being laid out by workhouse prisoners.

Gratuitous Treatment of Officers at Aix-Les-Bains.—The authorities at Aix-les-Bains, which is State property, announce that treatment there during the coming season will be entirely free for all sick and wounded officers of the allied armies, a valuable concession in view of the large number who have contracted rheumatism in the trenches or have been left with damaged or stiff joints as the result of wounds. A certain number of the principal hotels have been reopened in order to provide accommodation for visitors and the hotel proprietors' syndicate announce a special tariff varying from five to ten francs a day, inclusive, for convalescent officers.

For Osteopaths at Cornell Infirmary.—The students of Cornell University have petitioned the Board of Trustees praying that osteopaths be allowed to treat students at the Cornell Infirmary. At the present time students in the infirmary may not call in osteopaths.

American Association of Immunologists.—The second annual meeting of this association was held at the New Willard Hotel in Washington, D. C., on Monday, May 10. The following officers were elected: *President*, Dr. James W. Jobling of The Vanderbilt School of Medicine, Nashville, Tenn.; *Vice-President*, Dr. George P. Sanborn of Boston, Mass.; *Secretary*, Dr. Martin J. Synnott of Montclair, N. J.; *Member of the Council*, Dr. John A.

Kolmer of Philadelphia, Pa. Dr. Oliver S. Hillman of New York City and Dr. Victor C. Vaughan, Jr., of Detroit, Mich., were elected active members, and Prof. Emil Abderhalden of Halle, Germany, Prof. Victor C. Vaughan of Ann Arbor, Mich., and Prof. Edward C. Rosenow of Chicago, were elected to honorary membership. The association now has sixty active members and twenty applications for membership. The total number of members allowed by the constitution is one hundred.

Medical Association of Alabama.—The annual session of this association was held at Birmingham, Ala., April 20-24, 1915. Surgeon-General W. C. Gorgas, U. S. A., gave an address on the sanitation of the Panama Canal, and Dr. William Seaman Bainbridge of New York delivered an oration on surgery dealing with the sanitation of the gastro-intestinal canal. The election of officers resulted as follows: *President,* Dr. J. Norment Baker, Montgomery; *Vice-Presidents,* Drs. Edward B. Ward, Selma, and Abner N. Steele, Anniston; *Secretary,* Dr. Henry G. Perry, Montgomery; *Treasurer,* Dr. Jacob U. Ray, Woodstock. The next annual meeting will be held in Mobile.

The Woman's Medical Society of the State of New York held its annual session at the same time and place as the general State Society. The following officers were elected: *President,* Dr. Maud Josephine Frye, Buffalo; *Vice-Presidents,* Drs. Eveline P. Ballintine, Rochester; Annie Sturgis Daniel, New York City, and Mary Sutton Macy, New York City; *Secretary,* Dr. Mary Gage Day, Kingston; *Treasurer,* Dr. Florence L. McKay, Rochester; *Councillors,* Drs. Josephine Walter, New York City; Inez A. Bentley, King's Park; Agnes E. Page, Albany; Lois L. E. Gannett, Adams; Florence L. Staunton, Utica; Anna M. Stuart, Elmira; M. Louise Hurrell, Rochester, and Nathalie K. Mankell, Buffalo.

The Education of Women Physicians.—A complete set of moving picture films, showing in detail the work of educating women physicians in the Women's Medical College of Pennsylvania, have been especially prepared and passed by the Commission on Women's Education, for exhibition in the Temple of Education in the Y. W. C. A. Building at the Panama-Pacific Exposition.

The Arbuckle Memorial, completing the north wing of Long Island College Hospital, Brooklyn, was opened on May 24. It was presented to the hospital in memory of the late John Arbuckle by two of his sisters. It will house 171 male patients and, besides the wards and private rooms, it contains a clinical laboratory for forty-five medical students and three research laboratories for the use of the clinical research workers. With the addition of this wing the physical plant of Long Island College Hospital is completed.

The New San Francisco Hospital was dedicated on May 1. T. A. Reardon, president of the Board of Works, formally turned over the group of buildings to the city. A speech of acceptance was delivered by Arthur Barendt, president of the Board of Health. Mayor Rolph conducted the dedication and his address was followed by speeches by John O. Walsh, chairman of the health committee of the Board of Supervisors, United States Senator James D. Phelan, and Dr. T. W. Huntington.

Additions to Mt. Sinai Hospital.—Three buildings for the Mount Sinai Hospital, New York, are to be erected on the east side of Fifth avenue, between Ninety-ninth and One Hundredth streets. One will be nine stories high, for use as servants' quarters; another will be three stories high, to be designated as the pathological building and dispensary; the third will be three stories high and be used as the children's dispensary and for outdoor patients.

New Hospital for Diphtheria in Brooklyn.—Bids for the construction of a new diphtheria hospital in Kingston avenue, Brooklyn, were advertised last week. The hospital will be under the direction of the Health Department and will be one of a group of buildings devoted to the treatment of contagious and infectious diseases. The new building will be three stories high.

Hospital Saturday and Sunday Association.—A distribution of $110,000 has been ordered by The Hospital Saturday and Sunday Association to the associated hospitals on the basis of the amount of free treatment given to the poor, regardless of race or creed. To the general hospitals $58,355 was given in amounts ranging from $9,519 to $250; to special hospitals, $18,931 in sums of $4,648 down to $250; to hospitals for women and children, $18,749 in sums from $4,498 to $363, and to homes for incurables and convalescents, $13,963 in amounts varying from $9,525 down to $281.

Dr. John W. Wainwright has become a member of the editorial staff of *American Medicine,* having charge of a department of "Modern Remedies."

Dr. Samuel G. Dixon of Philadelphia has been reappointed by Governor Brumbaugh Pennsylvania State Commissioner of Health. This is Dr. Dixon's fourth term and he has just completed ten years of service. Under his able direction the Pennsylvania Health Department has been placed in the front rank of public health organizations.

Dr. Roy K. Flannagan of Richmond, Va., has been appointed assistant commissioner of health of Virginia, succeeding Dr. Allen W. Freeman, who resigned to accept the position of epidemiologist in the United States Public Health Service.

Dr. Benjamin Schwartz of New York City has been appointed Coroner's physician to fill the vacancy made by the appointment of Dr. Otto H. Schultze as medical examiner to the district attorney.

Dr. Thomas F. Harrington has been elected deputy health commissioner by the Massachusetts State Board of Labor and Industries.

Dr. Abr. L. Wolbarst was the guest of honor at a dinner given on May 12 at Wallick's Hotel by the physicians who had attended his Thursday night Genitourinary Clinic at the West Side German Dispensary and Hospital during the winter session. About twenty-five physicians were present and Dr. S. C. Grudberg acted as toastmaster.

The British Cancer Research Fund.—Dr. J. Alexander Murray has been appointed superintendent of the Cancer Research Fund and director of its laboratories in succession to Dr. E. E. Bashford, who recently resigned.

The California State Board of Health.—The California Legislature has passed a bill requiring the Governor to fill future vacancies on the State Board of Health by the appointment of practitioners of any or all the recognized systems of healing. The schools which seek representation are the homeopath, eclectic, and osteopath.

New York City's Death Rate.—There were 1,472 deaths in this city during the week ending May 15, making a rate of 13.23 per thousand of population. In the same week of 1914 there were 1,533 deaths.

There was a considerable increase in the deaths of children under 5. All other age groups showed a decrease. The death rate for the first twenty weeks of 1915 was 14.63, a decrease of .72 of a point from last year's figures for the same period.

American Association of Anesthetists.—The third annual meeting of this association will be held in San Francisco on June 21, under the presidency of Dr. Charles K. Teter of Cleveland, O. The secretary, from whom further information may be obtained, is Dr. James T. Gwathmey, 40 East Forty-first street, New York City.

Registry of Wet Nurses.—The Department of Health of New York City has made arrangements by which the names and addresses of women willing to give wet-nurse care, shall be reported to the Central Office of the Babies' Welfare Association. This information will thus be available to any physician in the city.

Charitable Bequests.—By the will of the late Emma L. Murphy of Philadelphia a contingent bequest of $5,000 is made to the Hahnemann Hospital for the endowment of a free bed in the name of Philip Potter Murphy.

By the will of the late Miss Josephine Lewis of Philadelphia a bequest of $1,000 is made to the Home of the Merciful Saviour for Crippled Children and residuary bequests to the Hospital of the University of Pennsylvania and the Episcopal Hospital.

By the will of the late Miss Sallie Roberts Smith of Philadelphia contingent bequests are made as follows: Hospital of the Protestant Episcopal Church, $10,000; Pennsylvania Hospital, $5,000; Protestant Episcopal Home for Consumptives at Chestnut Hill, $5,000; Christ Church Hospital, $10,000.

By the will of the late Patty D. Neill of Philadelphia the sum of $5,000 is bequeathed to the Hospital of the University of Pennsylvania for the endowment of a free bed in memory of her father, the late Dr. John Neill.

By the will of the late Elizabeth L. Roberts of Philadelphia bequests are made as follows: To the German Hospital $5,000 for the endowment of a bed in the names of Albert C. Roberts, Jr., and Elizabeth R. Roberts; to the Hospital of the University of Pennsylvania, $5,000, for the endowment of a bed in the names of Charles and Annie G. Parker.

By the will of the late Mrs. Emma Paul of Philadelphia a contingent bequest of $5,000 is made to Hahnemann Hospital and Medical College.

The will of the late Miss Helen Collamore of Boston contains a bequest of $200,000 to the Massachusetts Homeopathic Hospital for the erection of a new building, to be known as the Collamore Building. A further sum of $30,000 is also given to this hospital for the maintenance of three perpetual free beds. Bequests of $5,000 each are made to the Children's Hospital, Boston Instructive District Nursing Association, to the Perkins Institution for the Blind, to the Industrial School for Crippled and Deformed Children, and to the Boston University Homeopathic School of Medicine.

Medical Society Elections.—The South Carolina Medical Association at its annual meeting in Greenwood, April 20-21, elected the following officers: *President*, Dr. G. A. Neuffer, Abbeville; *First Vice-President*, Dr. A. B. Epting, Greenwood; *Second Vice-President*, Dr. J. J. Cleckley, Bamberg; *Third Vice-President*, Dr. Coleman Barnwell; *Secretary-Treasurer*, Dr. E. A. Hines, Seneca; *Councillors*, First district, Dr. A. E. Baker, Charleston; Third district, M. J. Walker, Yorkville; Seventh district, Dr. S. G. Baker, Sumter. The next meeting will be held in Charleston.

The Georgia Medical Society at its meeting in Macon, April 22-23, elected the following officers: *President*, Dr. W. S. Goldsmith of Atlanta; *First Vice-President*, Dr. O. H. Weaver of Macon; *Second Vice-President*, Dr. George Smith of Rome; *Secretary-Treasurer*, Dr. W. C. Lyles of Augusta; *Councillors*: Tenth district, Dr. J. A. Price, Milledgeville; Eleventh district, Dr. Lee Howard, Waycross; Twelfth district, Dr. E. T. Coleman, Graymont; *Delegates to the A. M. A.*, Drs. M. A. Clarke and C. C. Harrold. The next annual meeting will be held in Columbus.

The Tennessee State Medical Association at its annual meeting in Nashville, April 14-15, elected the following officers: *President*, Dr. E. C. Ellett of Memphis; *Vice-Presidents*, Drs. J. G. Price of Dyersburg, R. E. Lee Smith of Doyle and J. W. Johnson of Chattanooga; *Secretary-Treasurer*, Dr. Olin West of Nashville; *Delegate to the A. M. A.*, Dr. Jere Cook of Jackson; *Alternate*, Dr. J. McC. Hogshead of Chattanooga; *Councillors*, Drs. S. R. Miller of Knoxville, Scott Farmer of Cookeville, J. F. Gallagher of Nashville, A. B. Dancey of Jackson, and J. L. Andrews of Memphis. Knoxville was selected as the convention city for 1916.

The Brocton (Mass.) Medical Society, at its annual meeting on April 8, elected the following officers: *President*, Dr. Ezra W. Clark; *Vice-President*, Dr. M. F. Barrett; *Treasurer*, Dr. Joseph E. Brady; *Secretary*, Dr. Samuel W. Goddard; *Executive Committee*, Drs. F. H. Burnett, H. A. Chase, and C. D. McCann.

The Plymouth District (Mass.) Medical Society, at its annual meeting in Brocton on April 15, elected the following officers: *President*, Dr. N. C. King of Brocton; *Vice-President*, Dr. Nathaniel K. Noyes; *Commissioner of Trials*, Dr. Francis J. Hanley of Whitman; *Secretary*, Dr. Alfred C. Smith of Brocton; *Censors*, Drs. Fred J. Ripley of Brocton, W. W. Fullerton of Brocton, R. B. Rand of North Abington, Joseph Frame of Rockland, and James H. Drohan of Brocton; *Councillors*, Drs. A. Elliot Paine of Brocton, Frank G. Wheatley of North Abington, Gilman Osgood of Rockland, Alfred A. MacKeen of Whitman, and Fred J. Ripley; *Orator*, Dr. G. Ambrose Buckley of Brocton.

The Decatur County (Ga.) Medical Association, at its annual meeting at Bainbridge on March 31, elected the following officers: *President*, Dr. G. T. Clark of Bainbridge; *Vice-President*, Dr. B. Whisnant of Brinson; *Secretary-Treasurer*, Dr. Gordon Chason of Bainbridge.

The Rock Island County (Ill.) Medical Society, at its annual meeting held April 13, elected the following officers: *President*, Dr. J. M. O. Bruner, Port Byron; *Vice-Presidents*, Drs. W. G. Wiggins, Milan and H. A. Beam, Moline; *Secretary* Dr. A. E. Williams, Rock Island; *Treasurer*, Dr. A. P. Liepold, Moline; *Delegate to State Society*, Dr. J. W. Seids, Moline; *Alternate*, Dr. W. D. Chapman, Silvis.

The Hancock County (W. Va.) Medical Association, at a meeting held April 20 at Weirton, elected the following officers: *President*, Dr. H. R. Cramer of New Cumberland; *Secretary*, Dr. L. O. Schwartz of New Cumberland; *Treasurer*, Dr. G. E. Lewis of Chester; *Delegate to the State Society*, Dr. G. W. Wentz of Chester; *Alternate*, Dr. J. E. Richmond of Holidays Cove.

The Northeast District (Kansas) Medical Society, at its annual meeting in Lawrence on February 25, elected the following officers: *President*, Dr. G. W. Jones of Lawrence; *Vice President*, Dr. J. J. Brady of Frankfort; *Secretary-Treasurer*, Dr. Everhardy of Leavenworth.

The Long Island College Hospital, Brooklyn, will graduate eighty men on June 3. The annual clinical meeting of the alumni of the college will be held June 2 and 3.

The Jefferson Medical College, Philadelphia, will hold its ninetieth annual commencement at the Academy of Music on June 5, at 12 o'clock. The valedictory address will be delivered by Dr. Victor C. Vaughan, president of the American Medical Association.

The Army Medical School, Washington, will hold its closing exercises at the school, 721 Thirteenth Street, N. W., on June 1, at 2 o'clock.

Obituary Notes.—Dr. Thomas J. McLoughlin of Jersey City, N. J., a graduate of the College of Physicians and Surgeons, New York, in 1869, a member of the American Medical Association, the Medical Society of New Jersey, and the Hudson County Medical Society, medical director of St. Francis' Hospital, Jersey City, and for twenty-five years a member of the staff of the Jersey City Hospital, died at his home on May 12, aged 70 years.

Dr. Marshall L. Price of Boise City, Idaho, died of gastritis while returning to this country on the *St. Paul* on April 16. He was born in 1878 and was a graduate of the University of Maryland School of Medicine in 1902. He was buried at sea off the coast of Long Island within sight of his native land.

Dr. James Brainerd Field of Lowell, Mass., a graduate of the Harvard University Medical School in 1884, for twenty years treasurer of the Association of Massachusetts Boards of Health, and a member of the American Medical Association, the Maine Medical Society, and the Middlesex North District Medical Society, died at his home from pneumonia, on April 15, aged 56 years.

Dr. John Smallwood Patterson of Boulder, Col., a graduate of the University of Colorado, School of Medicine, Boulder, in 1902, died at his home on April 16 as the result of injuries received in a mine accident three weeks before, aged 36 years.

Dr. Fred Milton Smith of Portland, Me., a graduate of the Medical School of Maine, Portland, in 1905, and a member of the Maine Medical Association, and the Cumberland County Medical Society, died at his home, suddenly, on April 24, aged 36 years.

Dr. E. F. Sheehan of Ossining, N. Y., a graduate of the Albany Medical College, Albany, N. Y., in 1888, and a member of the New York State and Westchester County Medical Societies, died suddenly at his home on April 25 from heart disease, aged 55 years.

Dr. Archibald E. McDonald of Boston, Mass., a graduate of the Harvard University Medical School in 1865, formerly surgeon of the Ninth Massachusetts Regiment, and a member of the Massachusetts Medical Society, died at his home in Jamaica Plain, on April 27, aged 88 years.

Dr. Marmaduke Allen Wood died at Philadelphia on April 28 at the age of 65 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1874.

Dr. James Wilkes O'Neill, Mayor of Bergenfield, N. J., died on April 25, at the age of 61 years. He was a charter member of the American Red Cross Society, and he was formerly a bridgade surgeon in the Pennsylvania National Guard and at one time a United States Pension Examiner.

Dr. Henry B. Brusstar died at Philadelphia on April 25 at the age of 65 years. He was graduated from Jefferson Medical College of Philadelphia in the class of 1873. He was at one time quarantine physician to the Port of Philadelphia.

Dr. Isaac Welch Brown died at Philadelphia on April 28 at the age of 32 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1907.

Dr. James L. Terry of Lyme, Conn., a graduate of the College of Physicians and Surgeons, New York, in 1871, and formerly a practising physician of New York and of Philadelphia, died suddenly from heart disease at his home on May 2, aged 69 years.

Dr. William B. Rice of Lockport, N. Y., a graduate of the New York Homeopathic Medical College and Hospital, New York, in 1863, died at the residence of his daughter in Buffalo, N. Y., on May 1, aged 88 years.

Dr. William Austin Polglase, deputy superintendent of the Kings County Hospital, Brooklyn, N. Y., a graduate of the Chicago Homeopathic Medical College in 1878, a member of the American Institute of Homeopathy and the Academy of Pathological Science, New York, and formerly assistant superintendent of the Cumberland Street Hospital, Brooklyn, and the Metropolitan Hospital, Blackwells Island, died at the Presbyterian Hospital, New York, on May 4, aged 59 years.

Dr. George P. Griffing of Brooklyn, N. Y., a graduate of the Bellevue Hospital Medical College, New York, in 1873, and a member of the New York State and Kings County Medical Societies, died at his home in South Jamesport, Long Island, from heart disease, on May 5, aged 62 years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

ENTERIC IN THE EXPEDITIONARY FORCE—OPHTHALMOLOGY CONGRESS—EYE INJURIES IN WAR—PUBLIC HEALTH IN AUSTRALIA—THE LATE SIR W. R. GOWERS.

London, May 7, 1915.

The House of Commons was officially informed on Tuesday that the statistics of enteric fever among the British Expeditionary Force showed that 966 cases had occurred. Of these 780 had been analyzed; 142 were among those inoculated fully with two doses of vaccine, and there were 10 deaths, giving a case mortality of 7 per cent.; 157 had occurred among those who had only had one dose, among whom were 10 deaths, or a case mortality of 6.36 per cent. Among the men who were not inoculated there were 481 cases with 100 deaths, giving a case mortality of 20.9 per cent.

In order to appreciate the full import of these figures it must not be forgotten that 90 per cent. of the troops had been voluntarily inoculated and therefore among the 90 per cent. there had been 299 cases with 20 deaths, and in the other 10 per cent. 481 cases with 100 deaths.

The Annual Congress of the Ophthalmological Society was held on Thursday, Friday, and Satur-

day of last week under the presidency of Mr. Richardson Cross, F.R.C.S., of Bristol. There were many interesting papers brought forward and two set discussions were well sustained. One of these on "Ophthalmic Injuries in Warfare" was opened by Mr. Walter H. H. Jessop, who dealt with cases he had seen from the present war at Base Hospital No. 1 and at St. Bartholomew's Hospital. As most of the fighting was in the trenches the proportion of head and face injuries was larger than usual. The steel or cupro-nickel mantle of the bullet was often chipped, when a fragment might penetrate the cornea. The high initial velocity of the bullet might be reduced by ricocheting, in which case the wound might be more serious rather than less. There had been cases of bullets in the orbit without bursting of the eyeball, which he thought were probably due to ricochet. They showed mostly intraocular hemorrhage, choroidoretinal change, and detachment of the retina, generally complete. The most distressing cases were those in which the bullet passed transversely through both orbits. He had had some fifty of such and supposed they were caused by enfilading fire. If a wound was made in the orbital roof, the brain substance would fill it up, sepsis could not be prevented so it was best to leave it alone. If eyeball and orbit were much injured it was best to foment the wound, keep it clean with solution of sodium chloride, and delay removing the eyeball until the inflammation abated, but always remembering the risk of sympathetic ophthalmitis in the other eye—if a good one. In cases of destruction of both eyes it was better to wait until the danger of sepsis was over before removing the destroyed eyeballs in fear of meningitis. Injuries to the eyelids were very common, but they should be carefully examined, for the ball also was mostly involved. There was much edema and sutures should not be inserted. Conjunctivitis was not very prevalent in this war. In the Franco-German war sympathetic ophthalmitis developed in 55 per cent. of eyeball injuries; but in the American Civil War in only 16.14 per cent. Mr. Jessop said he had not seen such a case in this war—a result he attributed to the care in diagnosis and treatment, especially to the early enucleation of a ruptured globe. He had seen one wound implicating ocular nerves, caused by a ricochet bullet. Wounds of the skull vault were generally depressed and papilledema was present with increased intracranial pressure. Skull fractures near the occipital lobes often set up hemianopsia. At the beginning of this war he had many cases of complete blindness following great explosions, but sight returned on different days up to about a week. Deafness was similarly caused and in rare instances dumbness. Three men had extreme blepharospasm, so could not open their eyes for days. It seemed that the initial shock in these cases produced loss of consciousness; when this returned, sight, hearing, and speech returned also.

Colonel T. D. Lister, F.R.C.S., contributed the second paper in which he said the outstanding features of eye injuries in the present war were severity and for the most part the impossibility of employing conservative surgery. He grouped the cases as contusions, wounds, foreign bodies, functional cases, and head cases. In concussion if the bullet did not go through the orbit the fundus showed no changes. Ruptures of the choroid were rather frequent and might seem star-like or arranged in definite groups. The rest of the retina showed some pallor. Penetration of foreign bodies formed a most unsatisfactory group; many particles did not give a sensible *x*-ray shadow and if they did many fragments were non-magnetic. Two factors increased the poor look-out: (1) presence of more bodies than diagnosed; (2) friability of bodies so that they broke off when caught in the forceps. It was difficult to decide what to do when the sight continued useful. He considered that although a foreign body was contained, if there was no prolapse nor entanglement of the uvea or lens capsule, the risk of sympathetic ophthalmitis was *nil*. Though the eye would degenerate, useful vision might continue for a considerable time. But if signs of irritation did not abate he would remove the eye. Some interesting functional cases were then related, after which head cases injuries. Papilledema occurred in more than half the cases, but two-thirds of these only produced a blurring or slight swelling. The greatest swelling was met with in cases of cerebellar abscess. He did not regard hemorrhages or exudations as very important. Increasing swelling was the significant factor. From the examination of a number of cases Col. Lister and Dr. Gordon Holmes concluded (1) when the lesion occurred over the occipital cortex of one side only, the result was either hemianopsia or homonymous quadrantic defect on the opposite side; (2) when the bullet passed through both occipital lobes there was at first complete blindness, but in several cases this had gradually cleared centripetally after an interval varying from hours to days, leaving a central scotoma.

Dr. Perrin Norris, chief medical officer of the Australian Commonwealth Medical Bureau, gave a lecture this week before the Royal Sanitary Institute on the Evolution of Hygiene and Public Health in Australia, in which he told us that instead of administering a health department through a lay under-secretary, who might not be in sympathy with, or have a full understanding of the work, they put the matters in the hands of a professional man. They considered a minister of public health a necessity; that it was impossible for one municipality to control efficiently another's milk supply; that prosecution of a manufacturer of adulterated goods was more effective than that of the retailer; that instead of sanitary inspectors who measured success by the number of prosecutions it was better to have superiors whose standard would be reduction of adulteration. Their results in Australia were reduction of infant mortality as low as 60 in one State and 70 in others. Typhoid deaths reduced by 80 per cent., tuberculosis 50. From all causes reduced to 10.35—the lowest in the world, except in New Zealand.

Sir Wm. R. Gowers died on Tuesday. Born in 1845 he entered the profession in 1874, was associated with University College Hospital, and with that for the paralytic and epileptic. In 1879 he published his paper on "pseudo-hypertrophic paralysis" now called after him "Gowers' disease." In 1885 he gave the Lettsomian Lectures. In 1897 he received a knighthood in recognition of his eminent contributions to medical science and practice. He was elected F.R.S. and received a number of other honorary distinctions, both British and foreign. Of late his original work had been somewhat restricted by failing health, but there is much to his credit, especially as to diseases of the nervous system.

OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

RESIGNATION OF THE DIRECTOR OF HEALTH—DR. HEISER'S WORK IN THE PHILIPPINES—HIS ACCEPTANCE OF THE POSITION OF DIRECTOR IN THE ORIENT OF THE ROCKEFELLER FOUNDATION—HOSPITAL SHIP FOR THE MORO ISLANDS—BISHOP BRENT'S HEALTH WORK IN THE SULU ARCHIPELAGO—METHODIST HOSPITAL IN NORTHERN LUZON—EPISCOPAL HOSPITAL IN SAGADA.

MANILA, April 5, 1915.

THE most noteworthy and regrettable event for a long time in medical annals in the Philippines consists in the resignation of Dr. V. G. Heiser as Director of Health, which took effect recently. Dr. Heiser has been in the islands for about a dozen years, for a decade of which he was Director of Health. Taking over the organization for health matters created under the military government, Dr. Heiser developed and added to it until it reached a degree of efficiency which made it a model in the sanitation of the tropics everywhere. Able, tireless, fearless and with a broad grasp of the situation, his achievements were such as not only to bring honor to himself but to be regarded with the keenest pride by all Americans here. Sanitation lies at the basis of all industrial efficiency in these islands, and in Dr. Heiser the business interests felt they had the best of protection. For the home he was the shield of domestic health and happiness. His name will always be associated with the great sanitary regeneration of these islands, and such an institution as the Philippine General Hospital, which he created, will stand through time as the best of monuments. Under him, the great leper colony took form, practically universal vaccination was carried out, charitable institutions established, sanitary laws passed, and sanitary organizations created and expanded. A campaign of sanitary education has brought its gratifying results in every corner of the archipelago, and shows how ignorance and inertia can be made to yield to patient energy and unfaltering purpose. For a decade, every step in applied sanitation over here was associated with his name. He justly enjoyed the confidence and support of a succession of governors and members of the commission, and especially in Dean C. Worcester, the late forceful Secretary of the Interior, he possessed a tower of strength which enabled him to make great dreams come true. Dr. Heiser had refused many flattering offers for work elsewhere, which implied his separation from his life work here. In accepting the position of director for the Orient of the projects of the Rockefeller Foundation, for whom he is now agent, the Philippines still remain within his wider field of usefulness, and doubtless will be given careful attention and every legitimate advantage. Before leaving, Dr. Heiser was waited on by the officials and employees of the bureau over which he had so long presided and presented with a fine watch and chain as a token of appreciation and remembrance. It is understood that his itinerary will carry him to Borneo, the Federated Malay States, the Dutch East Indies, Eastern Africa and Egypt, where he will look into and report upon various sanitary projects which have been proposed, and within a year he expects to revisit the Philippines for the furtherance by the Rockefeller Foundation of sanitary work there. His brilliant services and achievements here have added a chapter in the progress of tropical hygiene and sanitation, of which the American profession and people will always be proud.

A bill passed the recent Assembly providing for a hospital ship for service among the Moro Islands of the South, to be operated along the lines of Dr. Grenfell's hospital ship work in Labrador. It is to meet the needs of the many out of the way places and islands that now never have seen a doctor or medicine that this floating medical service is to be organized. The general plan includes an agreement between the Philippine Government and a private philanthropic organization, understood to be the Rockefeller Foundation, for the cooperation of both in the above purpose. The Government is to give the use of one of its coast guard cutters, and the private agency is to appropriate 50,000 pesos to outfit it for hospital purposes. The Government is then to provide for the running of the ship, and the private agency is to appropriate 25,000 pesos per year to maintain the personnel and supplies of the hospital. This arrangement is to continue five years. The management of the medical work of the boat is to be under the Director of Health, but its operations are practically to be limited to the Moro Islands. The boat will doubtless prove a great civilizing agency and do much toward allaying the hostility of the fierce islanders toward the first outside government that has ever brought them under domination. The plan is to have a general itinerary among the outlying islands, stopping at various dispensaries and other points for collection of the sick and treating and operating on cases requiring the same and then going on to the next point. Any very serious cases may be carried along and brought to Jolo for transfer to the hospital there, where prolonged treatment will be given. The boat is to carry an American physician and nurse and several Filipino nurses and will operate as a connecting link between the medical base in Jolo and the outlying islands and places of medical relief. The plan will doubtless go into effect as soon as the humanitarian agency in the United States has had an opportunity formally to accept its share of the burden. The plan was one which had previously been entertained by Bishop Brent, of the Episcopal Church, but which could not be carried out for lack of funds. The Bishop was a strong supporter of the new arrangement before the legislators, the bill being introduced through the initiative of Dr. Heiser, representing the Rockefeller Foundation.

Close upon this comes word that the governor of the Department of Mindanao and Sulu has offered to exchange the new Government hospital in Jolo for the hospital lately erected by Bishop Brent in Zamboanga. The Bishop now has his field of educational and relief work divided between the two places and desires to concentrate his medical work in the Sulu archipelago, where he is operating several schools and a dispensary or so, and is desirous of further expanding. The governmental authorities are equally desirous of operating the hospital in the capital at Zamboanga as part of the general official sanitary scheme, so it looks as if some agreement for exchange would be reached.

The Methodist Church has just established a hospital of about twenty beds at Apani, on the northern tip of Luzon, under charge of Dr. H. G. Nickles. A hospital has long been needed here, since this large community opens up a vast hinterland without medical provision or assistance.

The Episcopal Church also has a fine stone hospital at its mission at Sagada, among the wild Igor-

rotes, nearly completed. It will have accommodations for about 40 patients and have a full medical and nursing staff and all modern appliances. A very flourishing dispensary service, operated by a trained nurse, is now in operation at Sagada.

3. Labyrinthitis Following Operation for Atresia. G. Berry.
4. The Diagnosis and Treatment of Some Rare Fractures. W. P. Coues.

1. Care of the Wounded in the European War.—R. Derby notes that in the treatment of wounds in the present war, a greater degree of conservatism has been shown than ever before, except in the case of compound infected fractures of the lower extremities. In these amputation is more early resorted to than formerly, with the idea of saving the individual many years of chronic bone disease. Otherwise, the methods employed are a combating of the infection by means of ample drainage and antiseptic irrigations.

2. The Allen Treatment of Diabetes.—L. W. Hill and J. L. Sherrick report that they have obtained good results with this method of treatment, which they regard as simple, safe, and efficacious in rendering and keeping a patient sugar free, in a much shorter time than is possible by the old method. The Allen method is characterized as the starvation treatment of diabetes. In carrying this out the two most important things to remember are the following: The diet should not be raised too quickly after starvation, and just as much attention should be paid to the protein intake as to that of carbohydrates. One should not be concerned if the patient loses weight; this loss will not hurt him.

3. Labyrinthitis Following Operation for Atresia.—G. Berry reports the case of a boy of fifteen operated on for a partial atresia with apparent improvement in hearing. Three weeks later and coincident with the springing up of troublesome granulation tissue in the tympanic cavity, a vertigo developed, which has persisted in spite of a radical exenteration and then a labyrinthine operation. Five weeks following this last operation, the closing off of the drainage from the meninges in the process of healing was attended by marked symptoms of meningeal pressure, which gradually subsided. The ear cavity became epidermatized in six weeks. Now, thirteen months after the first operation, the ocular nystagmus has become fairly well compensated, the hearing is apparently improved, but a muscular incoordination, though much better, continues. The consideration of the case naturally divides itself into two main headings, atresia and labyrinthitis, and is discussed as regards the age and operatve method for relief of atresia, the results to be expected, the cause of the vertigo in this case, and the time and the method for operating for labyrinthine vertigo.

4. Diagnosis and Treatment of Some Rare Fractures.—W. P. Coues discusses the following: Fracture of the trochlea of the humerus; children's colles fracture (subperiosteal fracture of the lower end of the radius); separation of the epiphysis of the first metacarpal bone; fracture of the carpal cuneiform bone; fracture of the fifth metatarsal bone by inversion of the foot, and the occurrence of the Vesalianum or bone of Vesalius in the foot, with its relation to mistaken diagnosis of fracture of the 5th metatarsal; separation of the lower epiphysis of the fibula; and fracture of the middle and external tarsal cuneiform. In many of these cases of obscure and unusual fracture, treatment does not differ from that in routine cases; but the diagnosis is all-important. Lack of recognition of seemingly slight fractures, particularly subperiosteal, may lead to deformity, even though at the time they seemed trivial affairs. This is particularly so of the long linear cracks in the bones of the leg. If these fractures are unrecognized harm may result in weight-bearing, causing spreading of the fracture and subsequent static deformity. Fragments may break through the periosteum, and excessive callus may form and cause trouble. Children often complain of surprisingly little pain in subperiosteal fracture; often there is very slight disability. There is no crepitus with a pure subperiosteal fracture. In a few cases, such as trochlea fracture, correct treatment is only by operation, for the joint will never renew its normal functions while the fragment is in it; and failure to make a correct diagnosis will lead to permanent disability.

1. A Treatment for Inoperable Cancer.—S. P. Beebe reports a series of cases in which favorable results were obtained with this treatment which was originated by A. Horowitz. The treatment consists of the repeated application of a poultice to the affected parts and the administration internally in the form of an extract, either as a liquid or as a pill, of certain substances contained in the poultice itself. The application of the poultice is followed by an intense reddening of the skin and, if the application is prolonged in the beginning of the treatment blistering may be produced. It has the effect of active counterirritation. However, the effect goes farther than this. The malignant mass in many cases gradually becomes edematous, softer than before, and sections of tissue taken in and about the tumor show that the lymphatics are engorged with leucocytes, and if the skin is broken there is a profuse serous discharge. The exudate which later on is produced in considerable quantities in the treated area contains large amounts of broken down cancerous material, serum, and leucocytes. The leucocytes are mainly of the large and small mononuclear type. There is at the same time an improvement in the general condition of the patient, evidenced by the relief from pain, increase in appetite, and a marked improvement in the toxemia or cachexia accompanying the disease. Some of the patients examined by the author before the treatment was begun in the hospital, had large, open, ulcerated tumors which previously had been the seat of active infection accompanied by a disagreeable odor. The powder from which the poultice is made contains a considerable number of substances of plant origin. Seeds, roots, bark, and flowers taken from a number of different plants are prepared in the form of a powder which contains the

following substances: Menyanthes trifolinta, Melilotus officinalis, Mentha crispa, Brassica alba, Anemone hepatica, Viola tricolor, Anthemis, Fructus colocynthidis, Lignum quassiæ, Urtica dioica, Radix rhei, Hedge hyssop.

2. **Arteriosclerosis.**—L. F. Bishop has advanced a so-called cellular theory of arteriosclerosis, according to which theory there is a disturbance of metabolism that results in the irritation and destruction of cells. This destruction is most often the result of an anaphylactic reaction of the cells against certain proteins of dietetic or bacterial origin, to which the cells have become sensitized. The treatment of the disease is hygienic and dietetic and includes well regulated exercise and appropriate internal medication. The author refers to original observation concerning the gross appearance of the eye in arteriosclerosis. Eminent clinicians of former days spoke of the "shininess of the eye" in what was then called "chronic Bright's disease." The supposition was that this was caused by an edema of the conjunctiva. It was present in many cases in which there was no suspicion of edema elsewhere. The study of the bloodvessels in the eye for the early detection of arterial changes is often spoken of. The author believes that the change in the appearance of the eye in arteriosclerosis is a visible manifestation of the cellular irritation that he regards as the cause of arteriosclerosis.

3. **Arteriosclerosis as Seen by the Ophthalmologist.**—W. B. Marple states that the retinal vessels are suspended in a completely transparent tissue, and under normal conditions the vessel wall is quite invisible. The two conspicuous signs of arteriosclerosis (aside from hemorrhages and degenerative spots) are (1) narrowing of the blood current without very evident changes in the wall, or perhaps with silver wire arteries and banking of the veins; and (2) white lines along the vessels. The latter are due to a thickening of the connective tissue coat (a fibrosis) which encroaches more or less concentrically upon the lumen of the vessel while the former, indicated by a narrowing of the blood column, and not by any visible change in the walls, is due to a prolification of the endothelium, which is always eccentric, displacing the lumen to one side. The latter (disease of the intima) is most probably a response to a circulating toxin which would naturally chiefly affect the internal coat; the former (thickening of the connective tissue wall) is probably a strengthening of the wall to compensate for raised blood pressure. The venous narrowing at an arterial crossing is the result of a phlebosclerosis limited to the point caused by the mechanical interference with the blood current at the point of crossing of an artery, perhaps by the walls of the latter. The abnormally high tension of the arteries probably assists in the compression of the vein under it. The obstruction to the circulation dams back the blood, resulting in hemorrhages.

6. **Arteriosclerosis and Uterine Hemorrhage.**—W. P. Healy notes that the common form of treatment for persistent bleeding from sclerosis of the uterine vessels has been hysterectomy. The *x*-rays, however, are often effective in the control and cure of these hemorrhages and may be used without fear of any harmful effect upon the ovaries, as then patients are all at or beyond the menopause. Recently Kelly and Burnam have reported very excellent results in the cure of uterine hemorrhage by the use of radium. These patients should be given the benefit of treatment by radiation either with *x*-rays or radium, in which the danger of a serious complication is practically nil, before they are subjected to the risk of an operation as severe as a complete vaginal or abdominal hysterectomy which, under the best conditions, is apt to have a mortality of from two to three per cent.

1. **Treatment of Gastric and Duodenal Ulcer.**—B. W. Sippy details a mode of treatment which consists essentially in efficiently shielding the ulcer from the corrosive effect of the gastric juice. This is accomplished by maintaining an accurate neutralization of all free hydrochloric acid, thus rendering the digestive action of the gastric juice inert from 7 a. m. until about 10:30 p. m., or during the entire time that food and the accompanying secretion are present in the stomach. In addition, it is accurately determined whether an excessive night secretion is present. If so, this is removed each night until the irritability of the gastric glands has subsided. This applies almost entirely to cases of duodenal and pyloric ulcer that have been associated with stagnation of food and secretion for one or two months and longer. Such cases almost invariably are attended during the night by a more or less copious continued secretion which should be removed by aspiration two or three times each night, if necessary. Usually after three or four days of accurate control of free acidity the excessive night secretion disappears. Subsequently the normal quantity (about 10 c.c.) of gastric juice present in the stomach during the night is left undisturbed. The neutralization of hydrochloric acid is accomplished by frequent feedings and the use of alkalies in carefully regulated but adequate quantities.

2. **Acute Lymphatic Leucemia.**—C. E. Simon and C. C. W. Judd report the case of a patient presenting the clinical picture of lymphatic leucemia of the acute type, from whose glands there was isolated apparently the same organism which appears to occur so constantly in Hodgkin's disease. Since Steele found an organism of the same order in another case of lymphatic leucemia, which likewise appears to have been of the acute type (judging from the clinical history), this can hardly be a coincidence, and naturally raises the interesting question of a possible relationship between the two diseases.

6. **Multiple Cartilaginous Exostoses.**—A. Ehrenfried describes a condition characterized by the occurrence of multiple more or less symmetrical cartilaginous and osteocartilaginous growths within and upon the skeletal system, generally benign, and resulting from a disturbance in the proliferation and ossification of the bone-forming cartilage. In addition there are certain typical secondary distortions and deform-

ities of the skeleton. An hereditary factor can be demonstrated in a large proportion of the cases. Hyperostoses above the affected epiphyses are the rule, but true exostoses are less frequent, and of secondary consequence. The author applies to this condition the name "hereditary deforming chondrodysplasia."

7. **The Celluloid Tube in Finger Injuries.**—J. S. Davis refers to the use of a celluloid sheet wrapped around the end of the finger in the treatment of traumatic amputations, in order to produce a more satisfactory cosmetic and functional result. He uses sheet celluloid, 1/200 inch thick. The stump is painted with tincture of iodine and the celluloid, after being soaked in mercuric chloride solution, 1 to 1,000, for a sufficient time, is sponged off with ether or alcohol. It is then wrapped around the finger and secured as a slightly tapering tube with narrow adhesive strips. Properly adjusted, it closely hugs the edge of the wound, and gradually becomes larger until it impinges on the first interphalangeal joint. The celluloid may extend as far beyond the finger tip as is needful, and serves also as a splint for the finger and a protection for the wound. In cases seen early a blood clot is allowed to form in the wound and serves as a scaffold for granulations. If the soft parts are lacerated and spread apart they are gathered together and held by the tube. Effort is made to stimulate the granulations and train their growth along the tube. Any desired medication can be poured in the tube or packed in with gauze. A loose gauze plug is placed in the mouth of the tube and over all a simple dressing is secured by a bandage. This gives a longer finger with improved function and appearance. Cases seen soon after the accident give the best results.

11. **A Diagnostic Sign in Gelatinous Carcinoma of the Breast.**—W. S. Halsted observed this sign in four out of five cases of colloid carcinoma of the breast—cases in which the colloidal portion of the new growth was large enough and near enough to the surface to be palpable. There was conveyed to the finger on testing for elasticity a peculiar sensation which in the first instance made the author apprehensive lest he had ruptured a possible capsule of the nodule, although there was no apparent alteration in its size or shape. The tactile impression might be defined as a delicate swish or crush of a jellylike structure under tension with the suggestion of a delicate bursting. In no instance has the author obtained the sensation twice in the same case nor has any assistant felt it on making the examination before or after it had been made by the author. Presumably there is lost to the physical properties of the tumor a something essential to the production of the sign.

1. **Arteriovenous Aneurysm.**—Sir William Osler first presents an historical survey of surgery of the arteries which began with Rufus of Ephesus and Antyllus. The latter devised for the treatment of aneurysm an operation which is practised to this day. Arteriovenous aneurysm is the rarest of all forms of aneurysm. It comprises two types: aneurysmal varix, in which there is a simple tangential opening between an artery and a vein, and varicose aneurysm, in which there is a sac communicating with both vessels. The physical signs are distinctive. Inspection may show diffuse pulsation at the site of the communication and moderate swelling, but not necessarily any early venous engagement. On palpation the characteristic thrill is felt—vibratory, rough, continuous, and increasing in intensity with the diastole of the artery. On auscultation the second characteristic physical sign is heard—a loud, rough, humming-top murmur, continuous, with marked intensification during the cardiac systole. As regards the outcome of these cases the following are noted: The aneurysm may remain unchanged for years and interfere little, if at all, with the patient's health and vigor. Spontaneous healing may occur, the orifice closing between the artery and the vein. Sudden death may occur either from heart failure or from embolism. Rupture may occur with fatal hemorrhage. In the crural vessels progressive disability may result from the varicose veins, thrombosis, and ulceration. The vascular tissue involved in the aneurysmal area may take on a nevoid growth. As regards treatment the author agrees with Subbotich "that arteriovenous aneurysms should be operated upon, as they offer small prospect of spontaneous cure, although they often remain stationary for a long time and cause relatively little trouble." Urgency is greater in the case of the lower limbs.

2. **The Etiology of Rickets.**—By L. Findlay. (See page 903.)

3. **Treatment of Wounds in War.**—Sir W. Watson Cheyne, in discussing Sir Almroth Wright's recent lecture on this subject, states that while the latter's studies concern wounds as they reach him at the base hospitals, already in a highly septic state, and in a stage in which antiseptics as ordinarily employed are of no avail, there is a preceding period, which Wright does not come across, in which the septic process has not yet taken root in the wound, and in which it may be eradicated by the proper use of antiseptics. It is on this period that Watson Cheyne's researches are concentrated, and at this stage the use of antiseptics presents to his mind the only possible chance of success. His work and Sir Almroth Wright's are in no way antagonistic.

2. **Birth Palsy.**—H. Platt states that for some time it has been held by most authorities that the lesion present in birth palsy is an injury to the brachial plexus in the neck; this occurs during delivery as a result of traction applied to the head with the shoulder fixed, or vice versa. The German school of orthopedic surgeons, most notably Lange and Vulpius, consider that a primary shoulder-joint or bone lesion is present, paralysis being either absent or of secondary importance. This view was originally propounded by Küster in 1889 who described the condition as a rotatory displacement of the upper humeral epiphysis. Last year Turner Thomas, of Philadelphia, brought forward new evidence in favor of the shoulder-joint lesion theory. Certain etiological factors are well established and accepted by all. In the vast majority of cases birth palsy is seen in an infant born after a prolonged and difficult labor in which there was a disproportion between the size of the child and the maternal pelvis. Statistics available show that the injury occurs more frequently in vertex than in breech presentations, but the exact relative proportions remain to be settled in the future from a large series of cases. Although there is at pres-

ent scanty evidence to support the theory expounded by Turner Thomas, there is a certain amount of evidence in favor of a primary epiphyseal or joint lesion in some cases of obstetrical palsy. It is probable that the combination of physical signs presented in birth palsy may be produced by a pure plexus lesion, a joint lesion, or an epiphyseal displacement. The differential diagnosis of the three conditions in a very young infant is well-nigh impossible. As the treatment is the same for all the diagnostic disability is happily not of great practical importance. Both Biesalski and Rosenfeld recognize two types—the primary nerve lesion and the joint lesion—but admit the difficulty of distinguishing between the two. It is a reasonable conception to hold at the present time that obstetrical palsy is in the majority of cases a primary plexus injury, but in a certain unknown proportion of cases is a shoulder-joint or epiphyseal lesion.

3. Decortication for Traumatic Empyema.—W. G. Spencer notes that in the present war cases which survive wounds of the thorax rarely develop empyema, and traumatic empyema does not now claim the attention devoted to it by the writers on military surgery in the past. The author reports a case in which empyema developed without obvious signs, the wound healing by first intention; nevertheless, in the course of three weeks from the injury the lung had become so bound down by inflammatory fibrous tissue that nothing but the modified Delorme's operation of decortication could have availed the patient. The discovery that the shelling out of the compressed lung from its inflammatory capsule is possible in recent non-tuberculous cases was made by Delorme, who described his operation of decortication of the lung in 1893. His method included the turning upwards of a large parietal flap so as freely to expose the capsule covering the compressed lung. This operation has been followed in a series of cases by a mortality from the operation of 15 per cent., which is much the same as the mortality after Estlander's operation. But Delorme's operation in its full extent is only needed for old-standing cases of empyema, although it has been reported that an operation combining removal of part of the chest wall with removal of the capsule compressing the lung was followed by re-expansion of the lung four years after the onset of the empyema.

Berliner klinische Wochenschrift.

April 12, 1915.

Uremia.—Strauss states that within the past eighteen months our conception of this subject has been notably modified as a result of continuous study, which goes back a dozen or more years. The conception which then obtained has now become verified, and the result of a study of 200 cases seems to prove beyond a doubt that uremia is an intoxication which stands in close relationship with retention of nitrogen in the blood. Despite overwhelmingly positive statistical finds, however, the author is forced to confess that in a few cases uremia occurred without nitrogen retention. As a rule, the healthy man retains from 20 to 40 mg. in 100 c.c. blood serum, while in the uremic man the figures are 60 to 130 mg., according to whether the vascular or tubular form predominates. These facts are now commonly admitted. There are minor points in which authors are not in agreement. For example, the destruction of the kidney in sublimate poisoning is not, as a rule, accompanied by uremia. The latter must be made to signify nitrogen retention in the blood, irrespective of all collateral manifestations. To what extent may this N-retention be manifested clinically? The answer is that only very high values of N-retention may be depended on to give clinical results. Retention of 150 mg. indicates a high degree of renal insufficiency, and is manifested clinically in a variety of ways —coma, convulsions, dyspepsia, asthenia. Recent authors have devised new varieties, new names, etc., as a result of which a number of conditions have been isolated which resemble true uremia and are known collectively as pseudouremia. The author believes that this division is at present sufficient. The main difference lies in the degree of retention. If this is 150 mg., or upwards, true uremia is present. We may also find the latter with retention as low as 120. Pseudouremia is characterized by retention nearly normal—not above 80. In the true uremia group we find clinically either asthenia or dyspepsia. Volhard mentions a tic-like form. In this true form convulsions need not occur. So-called pseudouremia comprises both convulsions, and mental states associated with high blood pressure. Uremic convulsions are those which accompany nephritis and nephrosis and for simplicity are called eclampsia. Here we find, as already stated, no extreme retention of nitrogen in the blood; yet dyspepsia is not infrequently seen in either form. In the comatose form bilateral twitchings are encountered. In pseudouremic eclampsia the convulsions often succeed one another rapidly, not only in the acute and subacute nephritis of childhood and adolescence, but also in tubular nephritis or nephroses. Puerperal eclampsia belongs in this category, for the normal retention of nitrogen in the blood is seldom increased. The mental anomalies of the so-called hypertonics lead us to the relationship which subsists between hypertension, arteriosclerosis, and renal disease in elderly subjects. This type may be left out of consideration here.

Scarlatina and Diphtheria as Social Plagues.—Benda emphasizes the relationship of disease plagues to the various strata of society. Thus tuberculosis is a disease of miserable social status, of starvation, filth and vermin. Diphtheria (in the U. S. A., at least) is regarded as a filth disease, perhaps without warrant. In Germany the author sought proof of the social status of diphtheria and found but little to help him. Older authors stated that it attacks all strata alike, although the poor must necessarily suffer most. According to Baginsky there is a "poverty component" in diphtheria. An entire group of experts state in effect that the lower the scale of prosperity the greater the incidence of the disease. This is offset in part by the fact that with modern arrangements for dealing with the poor patient the latter does not suffer as he once did. A final conclusion is that the prosperous and proletariat may be attacked with equal frequency, although the former must necessarily show a smaller mortality. In regard to scarlet fever, figures show abundantly that whatever the incidence the mortality was less in the well-to-do. The author now reports the results of an individual, prolonged investigation of figures and concludes that in diphtheria the danger of infection is least among the well-to-do, who live in sparsely populated neighborhoods and observe hygienic procedures. In scarlatina none of these factors play a dominant rôle, and the children of the well-to-do seem more exposed than those of the poorer classes.

Regeneration Following Renal Lesions. — Alfonso Papa finds that a lesion causing an interruption of the excretory tubules in the medulla is not followed by a cystic dilatation of the peripheral portions of these tubules which in the course of thirty days degenerate and are substituted by connective tissue. There then occurs a regeneration of tubules and a formation of new glomeruli.—*Giornale Internazionale della Scienze Mediche.*

Insurance Medicine.

THE GENERAL FACTORS DETERMINING MEDICAL SELECTION.

FROM "ALLGEMEINE LEBENSVERSICHERUNGSMEDIZIN" BY PROF. DR. GEORG FLORSCHÜTZ OF GOTHA.

(*Continued from page* 746.)

An investigation along these lines was instituted and Table III gives the results. It shows that it is quite immaterial whether the interval between acceptance and death is one to five or twelve or more years; the group of those who died of tuberculosis remains inferior and does not attain the constitution values of the controls. It is differentiated in itself according to the duration of insurance, but not more than is natural through the great hazard according to the high degree of *habitus phthisicus*. The constitutional inferiority (*habitus phthisicus*) is not the result of the tuberculous affection, it is the cooperative cause.

TABLE III.—AVERAGE MEASUREMENTS AND WEIGHTS OF RISKS DYING OF TUBERCULOSIS, GROUPED ACCORDING TO THE LENGTH OF INSURANCE

(Only Persons Between the Ages of 25 and 67 are Included in these Statistics)

Insurance Year in which Death Occurred	Number Dying of Tuberculosis	Average Age at Insurance	Height (Inches)	Chest			Weight (Pounds)
				Full Inspiration (Inches)	Full Expiration (Inches)	Abdomen (Inches)	
1-6	464	34.8	66¾	36½	34¼	32¼	156½
7-11	368	34.8	67⅛	37	34⅝	32⅝	159½
12 and over	395	36	67+	37—	34⅞	32⅝	161¾

Why, however, are the years 15-19 and 20-24 an exception? (Table II) The constitutional inferiority is not absent, but appears here under a different form than in the later years. All body measurements depend upon the height of the body as a fundamental measure; without a relation to the height of the body all measurements are worthless, and if the body height changes all the measurements likewise change. While, however, in our series of investigations the height in the ages from 25 upward shows such an insignificant variation that it may be assumed to be alike for all ages, it springs up during the youthful period, 15-19 and 20-24, of the tuberculous cases 3.7 and 1.8, respectively, over the height of the control cases; and consequently, with an average height of 167.3 and 171.2, the chest and abdominal measures and weight are quite different from those found in controls with a height of 163.6 and 169.4, respectively, for the same ages. The preponderance of bulk in the tuberculous is therefore only apparent, and in reality this remains quite considerably behind the values which assert themselves in normal human subjects of the same size. The constitution is just as inferior as in later years. Highly noteworthy, however, remains the fact that the height in the tuberculosis hazard plays a special rôle only in increasing years. In the fully developed organism there appears a complete equality in height among the controls, and here the other measures first come clearly in the foreground. Then, however, they speak, as Table II teaches, a very eloquent speech—the more eloquent the more the accession age advances. It is shown that these tuberculous subjects do not show the slightest tendency to strengthen in the ages in which strengthening is physiological. These organisms lack a "something" which does not lend itself to definition, but which is responsible for this backwardness, and becomes a superior culture medium for the tubercle bacillus. It is—we may once more emphasize—not "up to" us to get to the bottom of this pathological-anatomical or chemical-physiological "something." That is a task for pathological anatomy and its accessory sciences. Our duty ends at the moment in which we, by the aid of our method of statistical research, have recognized this "something," this insufficiency of the organism, as the undoubted proximate and important concomitant phenomenon of the tuberculosis hazard. For in this we have the handle which makes it possible for us to weed out tuberculous applicants—makes it possible, indeed, but does not guarantee it, for the results attained represent no more than averages from which deviations to the positive or negative side will occur in the individual, to whom in the last analysis the selection must pertain. Hence, along with the constitution values as many other factors as possible will have to be adduced which come into question according to other experiences or investigations with reference to the tuberculosis hazard.

Naturally it was of greatest interest and of importance for the alleged significance of the constitution in the tuberculosis problem to learn the actual deviations in our material from the general average of the normal risk as to degree and frequency. But this kind of investigation can be instituted only when a normal table can be procured which states for every age and every height the appertaining average for measure and weight. For only then does it become possible to state the deviation from the normal type of the individual case. But such a table was not at hand; there existed only a similarly computed table for weight alone which originated in American observations, and I owe it solely to the chief actuary of the Gotha Bank, Professor Dr. Karup, that I was able to carry out the investigation, for he constructed a table which I reproduce here as the first normal table computed for all body measurements (Table IV). Based upon this table we have another showing the individually observed deviations in their extent and frequency, both for those dying of tuberculosis and for the controls.

(*To be continued.*)

Results of Influenza from the Insurance Point of View.—Dr. De Haviland Hall suggests the difficulty of diagnosis with a given set of symptoms from the same conditions which may exist normally in an applicant. We see the applicant before us and we have no opportunity of knowing what his standard of health has been in the past; we have to take him as he stands before us. Possibly we find that he has a soft, feeble pulse, but a great many people, especially those who may live a long life, have a soft, feeble pulse. How are we to differentiate the soft, feeble pulse which is the result of previous attacks of influenza from that of a person in whom this pulse is habitual, and who has a better promise of longevity than a person with a fuller and more frequent pulse? The family doctor can recognize at once the altered condition in his patient, but not so the insurance examiner. Hall is convinced that influenza has a great effect on the myocardium, and that the cases one sees from time to time of sudden heart failure are undoubtedly due in their origin to influenza. Investigation should be made of the first sound of the heart and of the impulse to see if there are any signs of heart failure.—Life Assurance Medical Officers Association.

Book Reviews.

THE DIAGNOSTICS AND TREATMENT OF TROPICAL DISEASES. By E. R. STITT, A.B., Ph.G., M.D., Medical Director, U. S. Navy; Professor of Tropical Medicine, Georgetown University, etc. Price, $2.00 net. Philadelphia: P. Blakiston's Son & Co., 1914.

THIS small book takes up the subject of tropical medicine from the point of view of the teacher. It is designed to be a companion volume to the author's work on "Practical Bacteriology," but nevertheless includes an ample section on laboratory diagnosis in the consideration of each disease. The first part of the book is divided into sections on diseases due to protozoa, bacteria, filterable viruses, food deficiency and on helminthic infections, infectious granulomata, and tropical skin diseases. The second part is devoted to the diagnostics and takes up the blood, urine, temperature, etc., in order. The subjects are handled admirably. The author has a sane point of view and is obviously familiar with the literature of his specialty. The small size of the book is made possible by the liberal use of fine type. The subject of tropical diseases is of great importance not only in the tropical possessions of the United States but also in the Southern States, and should receive much more attention than it does at the hands of the average practitioner. To all who wish to increase their knowledge of this topic, this book can be safely recommended.

INTERNATIONAL CLINICS, a Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, etc. Edited by HENRY W. CATTELL, A.M., M.D. Volume IV. Twenty-fourth Series, 1914. Price, $2.00. Philadelphia and London: J. B. Lippincott Company.

THIS volume of International Clinics contains twenty-nine articles on Diagnosis and Treatment, Medicine, Surgery, Legal Medicine and Illustration. Most of the articles are extremely short, the one on the Abderhalden test being too short to be of value to the laboratory worker though containing many details which are of no use to the clinician. In three successive articles there are recommended three distinct methods of treatment for lobar pneumonia and in them are found some statements which have not been accepted by the scientific world. Mays says (page 34) that strychnine "is equal to digitalis in enhancing the function of the heart." Francis' brief contribution is wholly fantastic. Swan in a long article gives an adequate presentation of the subject of auscultatory blood pressure determination. The Medicolegal articles are of great interest. They are two, one on Expert Testimony by J. E. Willetts and one on Performing an Operation Without Consent by L. D. Bulette.

A NURSING MANUAL FOR NURSES AND NURSING ORDERLIES. By DUNCAN C. L. FITZWILLIAMS, M.D., Ch.M., F.R.C.S., Surgeon in Charge of Out-Patients and Lecturer in Clinical Surgery, St. Mary's Hospital; Senior Assistant Surgeon, Paddington Green Children's Hospital; Captain First City of London Field Ambulance, etc. Price, $2.00. London: Henry Frowde and Hodder & Stoughton; New York: Oxford Press, 1914.

FOR nurses, orderlies, and Red Cross workers this is as useful a book as we have seen. It contains all the essentials of the subjects which these people should know; and, if these essentials are grasped, much suffering will be relieved and the nursing and other help rendered will be more efficient. The volume is small, unpretentious, and decidedly practical, and the author clearly indicates the class of nurses for whom his book is intended when he says: "The 'doctor-nurse' is an abomination, while the highly trained, unsympathetic machine is useless." Many of our readers will be glad to have their attention drawn to this admirable volume.

RÖNTGEN-THERAPIE (Oberflächen- und Tiefenbestrahlung). Von Dr. H. E. SCHMIDT. Berlin. Vierte umbearbeitete und erweiterte Auflage. Mit 83 Abbildungen. Price, 6 Marks. Berlin: Verlag von August Hirschwald, 1915.

THE exhaustion of the third edition of this work in 1913 gave the author an opportunity to rewrite it and incorporate therein the vast amount of recent accessions to our knowledge. The physics of the *x*-rays and their physiological, pathological, and therapeutic possibilities, with full elaboration of technique, constitute a sort of first part, the balance of the work being devoted to the indications for use. Dermatology naturally heads the list, for the rays have been used in the great majority of chronic dermatoses. In internal medicine the chief use of the rays has been in certain diseases of the blood and ductless glands. The so-called surgical indications comprise those for tumors and granulomata, with especial emphasis on surgical tuberculosis and malignancy; and certain hypertrophies and neoplasms affecting some of the ductless glands. In ophthalmology the rays are used chiefly for neoplasms. In gynecology the indications show no change, but the technique here, as in all deep radiation, has undergone notable progress. The book, of pocket size and with flexible covers, is of especial value to the student or practitioner who utilizes spare moments.

ANIMAL EXPERIMENTATION AND MEDICAL PROGRESS. By WILLIAM WILLIAMS KEEN, M.D., LL.D., Professor Emeritus of Surgery, Jefferson Medical College, Philadelphia. With an Introduction by CHARLES W. ELIOT, LL.D., President Emeritus of Harvard University. Price, $1.75. Boston and New York: Houghton Mifflin Company, 1914.

THIS volume is of exceptional interest; it gives the truth about animal experimentation and its value to scientific research, and it also shows "the unreasonableness, inaccuracy, and indifference to truth and justice manifested by the antivivisectionists in selecting the premises of their argument against animal experimentation." To quote from President Eliot's brief introduction: "How many rabbits or guinea-pigs, is it justifiable to incommode or kill, in order to save the life of a child attacked by diphtheria? How many monkeys a competent experimenter be justified in sacrificing, in order to find a sure treatment for infantile paralysis? How many rats is it justifiable for men to kill, in order to protect a city from an epidemic of bubonic plague? Dr. Keen suggests at many points the reasonable answer to all such questions as these." Physicians, teachers, students, and laymen in general will find this volume of the utmost educational value; and in collecting these papers into one handy volume Dr. Keen has performed a real service to the profession and the public.

CORNELL UNIVERSITY MEDICAL BULLETIN. Vol. IV, Number 2, October, 1914. Studies from the Department of Neurology. Published by Cornell University in New York City.

THIS volume is made up entirely of reprints of studies issued from the department of neurology of the Medical Department of Cornell. The articles appeared first in various medical journals. They are classified under the following subjects: Historical, Diagnosis, Neuro-Physiology and Pathology, Psychopathology and Psychoanalysis, Neurological Economics, and Clinical. Of special interest to the general medical reader may be mentioned: "Mental Tests," by Dr. C. L. Dana (from the MEDICAL RECORD, January 4, 1913); "A Plea for the Recognition and Regulation of Venereal Diseases by the State," by Dr. R. T. Kennedy (from the Proceedings of the National Conference of Charities and Correction, Cleveland, Ohio, June, 1912); "The Occupational Neuroses," by Dr. Dana (MEDICAL RECORD, March 9, 1912); "The Effects of Narcotic Drug Addiction," by Dr. Kennedy (*New York Medical Journal*, July 4, 1914); and some of the articles on Psychoanalysis by Dr. H. W. Frink and Dr. C. P. Oberndorf.

AUGENPFLEGE. Von Prof. Dr. ELSCHNIG, K.K., Universitäts-Professor und Vorstand der Deutschen Univ-Augenklinik in Prag. Mit 21 Abbildungen im Text. Berlin: Verlag von August Hirschwald, 1915.

THIS well written monograph of 56 pages takes up briefly the consideration of illumination; use of eyes; cleansing the eyes; methods of applying remedies; bandaging; use of shields and protection glasses; prophylaxis in ophthalmia neonatorum; removing foreign bodies, etc. The work is of particular value to general practitioners and nurses.

DIE SYMPATHISCHE OPHTHALMIE. Erweiterte Probevorlesung von Privatdozent Dr. A. JESS. Price, 1 Mark. Halle a. S., Carl Marhold, 1914.

THIS brochure of 33 pages is a general review of the subject, practically beginning from the year 1835 when Mackenzie first published a classic description of the disease, and extending up to the present time. Theories of origin, modes of onset, and therapeutics are fully considered. A comprehensive biography is appended.

Society Reports.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held March 22, 1915.

THE PRESIDENT, DR. HOWARD LILIENTHAL, IN THE CHAIR.

Symptoms, Diagnosis, and Treatment of Chronic Intestinal Stasis.—Dr. G. REESE SATTERLEE read this paper which dealt with the borderline cases of chronic intestinal stasis rather than with acute surgical conditions. Intestinal stasis should not be confounded with constipation. The "Lynch-Draper-Saterlee-LeWald" conception was that stasis was a diffuse toxemia of the body cells, the result of aberrant biochemistry, usually but by no means always bearing a measurable ratio to the delay in the onward passage of the intestinal contents as visualized by the *x*-ray. Coombe said it was usually but by no means always due to the toxine resulting from the action of the proteolytic anaerobic bacteria on the end products of protein digestion. There were five important local factors in the etiology of stasis, namely: (a) constipation, (b) congenital malpositions and anomalies, (c) inflammatory and non-inflammatory adhesions and bands, (d) infection, and (e) functional disturbances of the epithelial cells of the gut, closely allied to the so-called disturbances of internal secretion. It was impossible to say which cause was uppermost, but given a combination of two of the first three factors, it was not difficult to understand how the colon might become a fruitful soil for infection. Evidences of intestinal stasis were classified by Coombe as physical and mental. The physical signs were a sallow skin, usually dry with tendency to urticaria or eczema, breath with the odor of gastrointestinal tract in the cadaver, and tongue soft, especially on the edges, and the dorsum coated. The nasopharynx might show chronic congestion and the patients be subject to frequent colds. In severe cases, pigmentation of the skin, especially around the orbits, might be seen; the hair might become brittle and seborrhea might be present. Some symptoms of stasis might be strikingly like those of hypothyroidism. Myalgia and neuralgia were very common and neuritis and disturbances in the function of the nerve ganglia were not infrequent. A large number of skin eruptions were probably the direct result of stasis or were influenced by it. In the heart and arterial system might be found cardialgia, pseudoangina, tachycardia, bradycardia, and arrhythmia. Flatulency was a fairly common symptom. The question as to the ability to pass gas *per rectum* should always be asked and the ability to take and pass an enema painlessly in the normal way. If either of these things were at fault there was strong probability of a partial obstruction. The mental symptoms were sadness, fatigue, irresolution, depression, lack of ambition, loss of memory, headaches, multiple phobias, vertigo, visual disorders, and ringing of the ears. The author discussed special conditions, dilatation of the cecum, megacecum, intestinal kinks and volvulus, ileal constipation, micro- and macra-colons, diverticula, the nonrotated colon, sigmoid disease and adhesions giving the special signs in each. He called attention to the frequency with which dilatation of the cecum was diseased as appendicitis and the appendix removed whether diseased or not while the diseased cecum remained. It was important to radiograph every case in which there was a long standing history of intestinal trouble, however simple it might seem. The medical treatment of simple cases of stasis without ptosis consisted in emptying thoroughly the intestinal tract, usually by the administration of castor oil in one or two ounce doses, repeated for three nights. The colon was then irrigated with ox-gall or hydrogen peroxide and normal saline solutions. Two quarts of the stronger solution were given with the patient in the dorsal position and then two quarts of the saline with the patient on the side, and then in the knee-chest position. From six to eight quarts in all were given by a competent nurse. Five or six inches was far enough to insert the rectal tube, as the tube might bend on itself if inserted further. All laxative medicines were forbidden and a laxative diet prescribed. The ordinary hygienic rules for constipation were strictly adhered to. Further treatment depended upon the character of the constipation. In patients having atony of the colon, proper massage and vibration would give good results if given daily for two weeks and every other day for two weeks more. This should be done by the physician himself or an attendant skillfully trained. The ordinary massage was useless. In the spastic type manipulation of the large intestine was harmful. Belladonna was administered three times a day and if necessary small doses of codeine. Rest was enjoined and hot applications to the abdomen, previous to the daily time for stool. It was important to urge this class of patients not to worry about their bowels and not to take any kind of cathartics or enemata. In the spastic type an enema of one pint of hot water was allowed at intervals. In the atonic type, strychnine or arsenic were useful in some cases. Electricity had its advocates. If the feces were dry, plain agar agar was given with meals as a routine, and plain water or oatmeal water in addition to other fluids were given at meals. Russian mineral oil was regarded as an adjuvant and given at first in severe cases. It was not a cure and should be eventually stopped. Relapses were not uncommon and should respond well to a short time treatment. In the treatment of intestinal stasis with ptosis, the same preliminary cleansing of the colon by catharsis and irrigation was employed, and also the same diet, hygiene, and colon manipulations. Abdominal support was imperative. Abdominal supporting belts or the Lane-Curtis abdominal plate might be permitted for the maternal coloptosis type in men but the corset was safer for women. Patients were instructed to elevate the foot of the bed gradually up to a foot or eighteen inches, thus giving the patients the advantage of gravity for one-third of the time. Radiographs had demonstrated a permanent elevation of the stomach and colon of two inches by these methods, which amount might measure the difference between sickness and health. The rule was abdominal support at all times when the patient was on the feet. The Wier Mitchel rest and feeding treatment and acto-toxic diet seemed to be a necessity in some cases, but as a rule it was better to keep these patients on their feet. The administration of autogenous colon vaccines in these stasis and toxic conditions was an important aid. The results were sometimes remarkable both on the general toxic condition and locally on the infected bowel. In cases of long standing that had resisted medical treatment those suitable for operative measures should be picked carefully. The amount of toxicity was no contraindication, but rather the age of the patient. The skill and experience of the operator and the type of operation must also enter into the question. A very much diseased colon should be removed. Partial colectomy seemed to be the operation of choice as the operation of complete colectomy was severe and the outcome uncertain. The after treatment was as necessary as the operation itself. Dr. Satterlee stated that in all his picked cases the operation and results had been successful.

Developmental Reconstruction of the Colon.—Dr. JOHN W. DRAPER presented this communication, in which he called attention to some of the fundamental facts of biology showing that complex vertebrates, with man at their head, were controlled by two factors, enzymes and nervous system; one inherited from antiquity, the other developed in relatively recent times. These two factors could not be expected always to work harmoniously, particularly when environmental and hereditary conditions were unfavorable. In the evolution of man nature was obliged to provide for the maintenance of equilibrium between these and many other factors of divergent origin, so that their convergence as compelling forms in the life of the individual today should, under favorable circumstances, not cause friction and consequent mechanical derangement. The author cited instances showing that with the over-development of one system frequently came the under-development of the others, and thus, as a result of changing environment and divergence or misdirection of atavistic pressures, humans, as well as other vertebrates, had modified the configuration of their bodies and recast the activities of their minds. Surgeons with their knowledge of biology should be the first to acclaim that stasis was by no means a simple mechanical condition, but in reality a profoundly interesting evolutionary problem which dealt with what might ultimately prove to be either an effort on the part of nature to weed out undesirables, or actually a chapter in the decadence of primates. It was well known that as a species attained high specialization, it tended to extinction. These phylogenetic considerations were one side only of the problem, but one of great interest and import. They

led directly to a consideration of ontogeny or the development of the individual. In general the influence of heredity upon stasis was prenatal, of environment post-natal. The fetus was entirely at the mercy of his ancestors; the growing child of his parents. Even though deficient at birth, many ancestral deficiencies might be compensated for. What slight evolutionary tendency to torsal change there might be in man was giving away to the flat chest and broad costal angle. There was an interesting correlation between the development of the stomach and cecum, both developing by diverticula from a preexisting simple undifferentiated tube. In some animals the cecum was highly developed and the stomach simple; in others the reverse was true. Up to the fifth week the human fetus could not be differentiated except by careful study from that of the dog or the pig. What wonder, therefore, that in adult man one should meet with final arrangements of the gut, which conformed on one hand to the carnivorous type, and on the other to the herbivorous. In man the terminal portion of the cecum was degenerated as compared with that of the rabbit; it was a vestigeal remnant of the herbivorous type. The developmental trend of the average human being was towards the omnivorous type. Modern embryology discarded the midgut. In the adult no dividing line could be seen, but it was located about 50 cm. oral to the ileocecal valve. Until the sixth week of fetal life, the canal was an undifferentiated tube, the large bowel being slightly smaller than the small. This ratio persisted until the fifth month. At the end of this time a diverticulum appeared in the posterior limb of the U-shaped tube. This marked the morphological dividing line between the large and small gut and from this diverticulum was developed the future cecum and appendix. Shortly after rotation took place, this being due to pressure from the rapid over-development of the small gut as compared with the great. After the cecum reached its resting place over the right kidney it was virtually quiescent until birth, when it gradually migrated to the iliac fossa. Perfect fusion of the different layers of the peritoneum was unusual. This often counted for the extraneous bands and veils found at operation. Furthermore, this failure of fusion left occasional spaces in the omentum or mesentery which might account for cysts of these organs if the lymphatic drainage was deficient. It might also lead to very unusual distribution of the gut in specialized cases. Fixation of the cecal colon through adhesion of its mesentery usually took place shortly after birth and was a physiological adhesion. Any departure from the normal was likely to result in the formation of adventitious membranes. This the author believed to be the universal origin of the many sponsored bands and kinks. Cecum and sigmoid were two of the most variable organs in the body, and, when ill-developed, were often responsible for grave functional disorders elsewhere. Efforts to standardize the form of man had been fruitless; in other words, variation was wide. There were many misconceptions as to the physiology of the colon. These had afforded plausible but erroneous bases or ill-advised surgical therapeusis of the organ. The colon must be considered as related to the small gut. The duodenum was the crucible in which the forces of life were fused. The importance of the vital functions of the stomach and the great gut had been grossly exaggerated. Much that appeared to be stomach was functionally and surgically duodenum. The entire hydrolysis, amylolysis, and emulsification, which accompanied the preparation of all food, was begun and ended in the duodenum. Stomach and cecum and small gut might be resected without threatening life, but this could not be said of the duodenum. All the chatter about indiscriminate unphysiological operations for stasis was futile in view of the limited knowledge of the duodenum and of the chemistry of carbohydrates and fats. In a previous paper the author had shown that some former conceptions of the physical condition of the contents of the colon were erroneous and he had also called attention to the inhibitory activity of the terminal ileum and its great surgical import. Ileac inhibition, normally complementary to the ileocecal valve, might under stress become supplemental to it. Barber had shown that this same law held in the case of the ureter and the utero-vesical valve. Barber had also shown experimentally and they had verified it in some of their cases, the pernicious influence of partial peripheral obstruction upon the cecum and duodenum. In general, then, they had not yet reached any definite conclusions or found any single method which adequately met all the intricate associated biological requirements outlined, or could they hope to do so until such a time as the chemistry of alimentation was better understood. The writer said he wished to go on record as protesting against the indiscriminate non-physiological, mechanical operative interference with the alimentary canal which was so much in vogue today. Surgical therapeusis to succeed must be based upon inductive study of the physiological mechanism and chemistry of the parts.

The Lynch-Draper Developmental Reconstruction: A Further Study.—Dr. JEROME MORLEY LYNCH read this paper in which he stated that the authors wished to present a further report of their studies upon the surgical physiology and therapeusis of the colon. They defined stasis as "a diffuse toxemia of the body cells, the result of aberrant biochemistry, usually but by no means always, bearing a measurable ratio to the delay in the onward passage of the intestinal contents as visualized by the *x*-ray." They considered the unexplained morbid biological processes, which caused death in acute intestinal obstruction, to have some probable relation to the condition known as stasis, and emphasized the fact that this symptom complex should not be confused with constipation. In their experience, true diarrhea rather than constipation, had often existed as an accompaniment of genuine stasis. In the introductory portion of the paper they dealt with the important relationship of biology and heredity to the general subject of gastroenterology, and cited numerous instances from the literature of biology as well as from the personal studies of the authors, in human beings. They considered it probable that impaction of feces, almost always known to accompany enteric cancer, was evidence of a reflex inhibition of peristalsis by an enzyme from the growth or through other biological media, probably representing an effort on the part of nature to splint the gut and allow a natural curative process full play. In the authors' experience the greatest amount of impaction accompanying such cancers was not present because of mechanical obstruction, but occurred in the presence of small malignant nodules, laterally placed and incapable of impairing the size of the lumen by their mere presence. They contended that the generally accepted laws for the transmission of malformations of the alimentary canal held good in the same ratio as had been demonstrated in the better known deviations form the normal. The essayists furthermore discussed the interesting correlation that existed between the development of the stomach and cecum, and showed that it was logical to expect some adults, coming perhaps from a herbiverous line of ancestors, to present a cecum suited in general to that type, but ill-supported for accommodation to man's upright condition and lacking also the delicate mechanism of the true herbivorous form. A high degree of specialization carried with it frequent changes or limitations within the organism, which were not always compatible with its environment. This was true in man and might be cited as an instance of the familiar biological aphorism, that as a species tended to specialization, it tended also to extinction. From the standpoint of therapeusis, the essayists showed that they had tried all of the many surgical procedures which had been advocated for the treatment of stasis, but none in their hands had given as good results as the developmental reconstruction of the colon, which operation they had performed twelve times. This procedure entailed the removal of sufficient of the terminal ileum to include, if possible, the inhibitory segment, or at least a portion of it, the appendix, cecum, and ascending colon, and a portion of the transverse to the region of the middle colic artery, *en masse*, the ileum being inserted into the transverse colon. It was called a reconstruction operation because it replaced the ileocolic stoma to the hepatic region, namely, to that which it occupied at birth after rotation and before descent.

The authors showed a number of cases, all of whom had been human derelicts and over whom a gratifying clinical change had come since the operation. Pathological reports of the twelve ceca showed in every case marked departure from the normal; in three polyposus was well advanced; in several the fibers of Auerbach's plexus had vanished, and in others the mucosa was virtually destroyed.

Roentgen-Ray Diagnosis (with Lantern Slides).—Dr. LEON T. LEWALD presented this communication and said that this study of intestinal stasis was of special interest to him. The cases referred to the Roentgenologist should not have the Roentgen ray examination limited to examination after injection of the colon only.

The examination by means of the opaque meal would throw much light upon the subject, as the question of pathological physiology was as important as one of pathological anatomy.

The first case illustrated the necessity of a most thorough Roentgen examination. The patient was emaciated and constipated, but the cause of the trouble was located high up in the digestive tract. He had a most pronounced cardiospasm which had existed for some thirty years and be constantly regurgitated large amounts of food and liquids so that the stomach and intestines were receiving so limited an amount of material that after absorption of the nutritious parts little residue was left. The patient had responded to mechanical dilatation. The next case was one of extreme ptosis of the stomach, water-trap type, with a large residue remaining in the stomach at the end of the sixth hour. There was also a marked ptosis of the transverse colon. A carefully performed suspension operation by Dr. Draper benefited this patient greatly. The slides showed the stomach and colon remaining in good position nearly a year after the operation. The constipation in this type of case appeared to be relieved by the suspension operation. In conjunction with this case were shown slides illustrating this woman's daughter, 18 years of age, who showed ptosis of the stomach and colon almost commensurate with that of the mother. Dr. LeWald believed that most of the cases of ptosis of this type have a congenital origin. In this connection Dr. LeWald also showed slides of two brothers with similar degrees of ptosis of the cecum. A series of slides were then shown illustrating delay in the ileum. The cases were all due to definite peritoneal bands of adhesions resulting from some previous inflammatory process. Dr. LeWald had seen very few cases of so-called "Lane's Kink."

The next group of slides illustrated cases of non-rotation of the colon. The correct diagnosis of this condition was at times of vital importance prior to undertaking an abdominal operation. The condition had been described by Huntington from an anatomical standpoint, and surgical cases had been reported by Lynch, Downes, Mayos, Vosburgh, Delatour and others. Dr. LeWald had encountered five cases. The condition was entirely different from complete transposition of the viscera, twelve cases of which had come under his observation. A series of slides showing extreme variations in the length of the sigmoid flexure were next shown. This offered a new field for surgery. Many cases had been benefited by reconstruction of the colon after the method of Lynch and Draper; the shortening of the proximal colon compensated for the long sigmoid and seemed to overcome delay there. Other cases seemed to require resection and end-to-end anastomosis. A slide was shown of an enterolith which had formed in one arm of a greatly elongated sigmoid loop. Two cases of diverticulitis and one of fluid in the peritoneal cavity were shown. A series of slides showing the appearance before and after the reconstruction operation of Lynch and Draper completed the demonstration. The absence of the ileocecal valve did not seem to materially influence the motor functioning of the intestinal tract in these cases. A case was shown of vicious circle in the colon due to anastomosis of the cecum and sigmoid. Dr. LeWald believed that partial resection of the colon was better than a short circuiting operation. He had known of a case where the tip of the appendix had been literally blown off one week after an ileosigmoidostomy.

Dr. Fenton B. Turck said that if any lesion of the stomach or duodenum occurred following the intravenous or subcutaneous injection of cocci or bacteria, it invariably appeared in the solitary lymph follicles, which acted as excretory channels in the same way as did Peyer's patches in the small intestine. Toxins as well as injected bacteria produced an inflamed appearance, an elevated irregular ring with a central indentation bearing a resemblance to a peptic ulcer. On microscopic section this might show a smaller or larger collection of lymphoid cells with some necrosis and perhaps round-celled infiltration, but these all healed up and were not peptic ulcers. The photographic reproductions in the published report of Dr. Rosenow's work showing this appearance of elevated lymph follicles had led Mayo to say that Rosenow's work required further experiment, for the injected streptococci had not produced chronic ulcer. Holman's objections were based on the fact that, owing to the ease with which streptococci entered the tissues from the normal intestine or respiratory tract, isolation of streptococci from experimental animals could not be used as proof that they were the same as those injected. He further showed that injections of bacteria, particularly streptococci derived from the normal alimentary or respiratory tract, brought about invasion. Canavan and Southard questioned the effect of the cocci forms and claimed that while these might produce some irritative effect they produced no destruction. The blood vessels might be injured by streptococci. In this connection Klotz found that in twenty cases of infection having a destructive effect upon the vessels ten were caused by the bacteria of the colon group, five by the pneumococci, and only three by streptococci. The paratyphoid bacillus had been obtained in culture from many typical ulcers of the stomach and duodenum but no streptococci. No agglutination occurred with the streptococci, only with the paratyphoid bacilli. These typical peptic ucers might have been considered as due to streptococci, perhaps originating from the mouth. Great caution must be exercised, as Billings had recently stated, not to diagnose a condition of the patient and say outright that the mouth was related to it, for Pickerill and Champlaton found the same flora in the mouth of Maori children as in the European subject, and yet the Maori children were free from dental caries or systemic diseases, so that the immunity was not a question of the type of oral microorganism. It had been argued that the streptococci might undergo some changes in the tissues and assume a pathogenic character, but Theobald Smith had shown that no such mutation occurred. This agreed with the work of Holman, Cecil, and others. It was difficult to assume the pathogenetic rôle of these strains of streptococci from the mouth in peptic ulcer. The speaker said that in 1895 he had published the results of three years bacteriological work which indicated some relation of the mouth, nose, and throat to gastric disease. This had led to a more definite study of the intestinal flora in relation to diseases of the stomach and duodenum which indicated that the intestinal flora played an important rôle in the etiology of peptic ulcer. Recent developments showed (American Gastroenterological Association, 1914), that the bacteria passed into the submucous tissue and were there destroyed, creating by this destruction an alteration in the circulation, a reduction in the anti-ferments, and, as the process continued, ulcers in various stages, depending upon factors that permitted either constant or periodic invasion from the intestinal lumen.

Dr. Dudley Roberts of Brooklyn said that it was impossible in the few minutes permitted him to more than briefly touch on a few of the interesting points that had been brought out by the presentation of this remarkable symposium on "intestinal stasis." In the first place he thought it was well for them to realize that they knew very little about the toxemias that were said to arise from the intestinal tract. It was distinctly a fad at the present time and he was of the opinion that it was far less frequent in its occurrence and less important in its results than some would have them believe. From his own study of these cases it seemed to him that many of them were of small intestinal origin rather than colonic and neither stasis nor putrefaction was responsible for their occurrence. They knew very well how toxic was the secretion of the traumatized duodenum. They knew, it was true, very little about the toxic possibilities of products of digested food substances and the influence of functional sufficiency of the liver. He thought they should find that, after the removal of the colon, the toxic symptoms frequently persisted. So far as treatment was concerned, he emphasized the fact that it was incorrect to say that because a case had been treated by a reputable medical man without success, surgery was justified. Internists who might be thoroughly competent in treating many other conditions had frequently given the study of these cases scant attention and made only the most superficial efforts over a short period to correct the suspected abnormality. He recently saw a young woman who had long been under observation in one of their best hospitals treated for a supposed neurosis by a rest and forced feeding. Their examination disclosed the fact that she had an enormously dilated colon with a kinked sigmoid flexure entirely sufficient to account for her local complaints and general condition. On the other hand, they did not as yet know what to do for many of these cases because they did not know just what was responsible for the pathological conditions and symptoms. They were not dealing with a single variation from normal but a wide variety of abnormalities. He believed that they would see medical measures devel-

oped in the course of the next few years to a point of efficacy far beyond that of the present time. As an example of this might be mentioned colon massage which, as ordinarily practised, was of comparatively little value as the operator did not know where the bowel was or where the seat of partial obstruction. It had been his practice in recent times to have the trained masseur study the colon with him fluoroscopically when a case was to be so treated and observe in what position it was necessary to put the patient to make colon manipulation possible. For example, the pelvic cecum which retained fecal residue could only be brought under the fingers with the patient in the exaggerated Trendelenburg posture, while the high lying hepatic flexure required a sitting posture. So far as surgery was concerned, he felt they must recognize that it was necessarily accompanied with a considerable degree of mortality if any resections or anastomoses of the bowel were carried out. There was a great deal of doubt whether supposed toxic conditions were any indication whatever for operation even when there was evidence of intestinal stasis. It was hardly justifiable to submit a patient with a minor disability to any surgery having a high degree of mortality particularly if the end-results were doubtful. He was convinced that surgery was required for the relief of a fairly large group of patients with lower abdominal disability accompanied frequently by gastric symptoms. Many of these patients had been subjected to appendectomy with no relief of their complaints. But he knew of no field of surgery in which greater operative experience and judgment was needed to determine what was best to be done even when cases had been very thoroughly studied before operation. Some type of anastomoses or resection was needed in the occasional case but he had been surprised to find what excellent results were possible by simply cutting bands of adhesions and fastening the prolapsed cecum in the right iliac fossa. Until he had had the opportunity of watching some of these cases post-operatively that had been observed for long periods before operation it did not seem possible that such a simple procedure, comparatively free from mortality, could give such perfect relief from disability. It must be recognized that their knowledge of the whole subject was still very incomplete and that their conclusions as to some of the functional incapacities of the bowel as shown by the *x*-ray had not as yet been checked up by the study of large series of cases free from abdominal disability or disturbances of health. He had been surprised to see what perfect health and comfort might be enjoyed by some patients afflicted with general adhesions and definite functional incapacity of the intestine shown by radiographic study. In others of this group they had found the relief of minor disability and failure of bowel function were relieved entirely by the institution of the proper dietetic regimen. In other words, that the bowel could compensate for structural abnormalities and functionate properly without local or general disturbances of health. It seemed to him that they were dealing with a class of conditions so varied and complex in their nature as to require the most thorough and persistent study before they were dismissed as incurable or submitted on the other hand to radical alterations of their anatomy.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Two Hundred and Sixty-ninth Regular Meeting, Held March 5, 1915.

Dr. Thacher in the Chair.

Case of Plastic Operation on the Nose. — Dr. Abbe showed a patient after completed plastic repair, following extensive removal of cancer of the nose. For a year a bleeding, warty growth on the patient's nose had been treated by acid nitrate of mercury and salves, growing worse rapidly until the entire surface of the nose from between the eyes to the nostrils and from cheek to cheek was diseased and eaten away. The patient was referred to Dr. Abbe by Dr. J. B. Murphy of Chicago. The disease was recognized by microscopic and clinical observation as squamous celled epithelial cancer, which neither radium nor Roentgen ray therapy would affect favorably. A wide excision left a large defect to be covered, possibly by a disfiguring flap from the forehead. Preference was given to the double transplantation flap method of Steinthal, on account of the ample flap to be obtained. Two vertical incisions, three inches apart, were made over the upper sternum, five inches long, the lower ends joined by a cross cut and a thick flap raised which included periosteum and a strip of bone chiseled up with the flap. The left forearm was brought up so that the hand rested on the right shoulder, and an incision was made in the skin of the forearm, corresponding to the lower edge of the sternal flap. Close suturing of this flap edge to the edge of the forearm cut was made and the arm and hand fixed to the chest and shoulder by adhesive and plaster of Paris dressing. In two weeks the nutrition of the chest flap was well sustained from the forearm end, permitting division of the upper end from the sternum. Three days were given to promote the best circulation from its forearm attachment and it was then stitched by its freshened edges to the freshened edges of the nose defect, and the forearm fixed to the head by laying the hand flat on a previously applied helmet of plaster of Paris. The entire forearm, shoulder and head were encased in a light plaster of Paris bandage. The patient fed himself as his mouth was free below his fixed hand. In eighteen days the flap had acquired ample nutrition from his face and it was cut away from his forearm. It had a fine vascularity after this second transfer and was now stitched throughout its entire margin to the nostrils and cheeks. After this second transference had been safely accomplished two minor trimming and suturing operations were done under local anesthesia and the present excellent, living, healthy, ample new nose had been accomplished. The advantage of this method for this case was in having unlimited freedom to cut away the disease, as a flap as large as necessary could be brought up. The disadvantages of the method were—first, a tedious and almost exhausting confinement in plaster casings; second, a not altogether sightly, though healthy, ample flap repair. The disadvantage of these transferred flaps, of which he had made many, was that being cut off from all their original margins they lost their vasomotor supply and also underwent some fibrosis, thus giving them an unnatural waxy pallor, which contrasted with the skin of the face. This did not occur with the large flaps of the forehead, turned down on a pedicle between the eyebrows, which were fed by the supraorbital and nasal arteries without loss of vascular continuity, and hence in proper nerve relation with the general vasomotor system. In proper cases Dr. Abbe said he would, on the whole, prefer the so-called Indian method of forehead flap.

Dr. Abbe, replying to question, said the transfer from the arm was done four weeks ago. It had shrunken already. The requisite graft was too extensive to take from the arm; a large amount was needed and one could take an enormous mass from the chest. The graft would probably always appear anemic. He said he had cut the cancer very widely away. The cosmetic effect was important. In one case of a lady, eighteen years ago, he had done the flap operation and there was no recurrence of disease. If one stitched the chest flap to the arm alone for ten days it got enough nutrition. There was at present a healthy mucous lining on the under side. This case was one of squamous celled cancer and radium would not affect it.

Arteriovenous Aneurysm of the Carotid.—Dr. J. A. Miller presented this patient. He said he felt he ought to apologize to surgeons for presenting this case. The woman had not really come in the capacity of a patient. He happened to see her when she brought her boy to the clinic and he noticed a swelling on her neck. Patient said it had been there for sixteen years. She was a bystander in a quarrel and was struck with a knife below the angle of the jaw. She had considerable shock and felt faint almost immediately with profuse bleeding from the ear which saturated all her clothing. She was removed to a hospital. She recovered soon from the shock and went home. After the injury she heard a pulsating, roaring noise. Her eyes became crossed, she did not remember how. At first she had no swelling, but the roaring noise persisted. The trouble with the eyes subsided. Six years ago, after childbirth, she had a very decided increase in the tumor. Since then the swelling had slightly increased, but she had had no pain or inconvenience except the roaring, which she had become accustomed to. At present there was a pronounced thrill, most marked in systole, and a marked swelling of the vein down to the clavicle with a murmur heard all over. There was nothing to be heard below the clavicle. The pulsation could be seen internally in the mouth in the carotid. There must

have been a wound of the artery and vein. There had been no exophthalmos at any time. There must have been an injury to the sixth nerve, although the fourth was the one most often involved. The question was, what was the hemorrhage from the ear? Often cases of the cavernous sinus were associated with fracture of the base communicating with the outer canal.

Dr. ABBE asked if it ran up to the temporal vein. He said the anatomical problem would have to be studied. It might be a mastoid branch. There might be an opening between an artery and vein of small size which enlarged the veins about them. The artery was small. The vein was not the jugular.

Dr. KNAPP asked if the woman were deaf, and if the tinnitus had kept up. He said he thought the sixth nerve must have been injured at the apex of the petrous pyramid; the fracture possibly involved the anterior boney wall of the auditory canal, thus the labyrinth escaped. If it had struck the cavernous sinus she must have had exophthalmos.

Dr. MILLER asked the meeting if they thought the hemorrhage was due to a fracture; the woman had not become unconscious; she was dazed. To have affected the nerve the injury must have extended into the artery. He would like to know how they would account for her being cross-eyed about a week. That must have been in the carotid with involvement of the cervical nerve. There must have been pressure inside of the skull. A very puzzling feature also was the hemorrhage. In answer to Dr. Potter he said that after the injury the patient was stiff, and black and blue.

Case of Goiter.—Dr. ROBINSON presented this case. The patient, Mrs. C., twenty-eight years, widow, came under his care some weeks ago. She had a moderate sized goiter, the cause undetermined, unless grief and care of a sick husband, who died of tuberculosis, explained it. The husband had died a year previously. She noticed swelling of the neck six or seven months ago. At times the neck swelled considerably, up to 13.5 or 14 inches, then it would diminish to 11.5 inches. The cause was undetermined. There was no occular trouble, no bowel trouble, no irregularity of menses. The last period was very profuse for no apparent reason. She had a slight cold at the time. She had fairly good health previous to her husband's illness. At present there was marked acne of the face. The appetite was good. She complained somewhat of nervousness and tightness in the chest. The heart's action was slow and somewhat feeble, the pulse slow and rather weak and irregular. There was a soft blowing murmur at the apex of the heart, systolic. No blood examination was made, but she was apparently anemic. The patient had been taking arsenoferratose for some weeks with much benefit. She was less nervous, had a better color. Dr. Robinson said he was not quite sure whether he had to do with a simple case of goiter, or with incipient Graves' disease.

In answer to questions, Dr. Robinson said the circumference of the neck had diminished from 14.5 to 11.5 inches. He had taken the patient's own measurements. There was general nervousness and a slight blowing murmur with irregularity of the heart. He did not think the symptoms were those of Graves' disease. There was no trouble with the teeth.

Dr. MILLER said he wanted to ask Dr. Abbe the facts in regard to removal of the thymus, as reported from Germany.

Dr. THACHER said that in New York City a case had been tried where part of the thymus had been removed and the *x*-ray applied to the thymus with good result. He thought, however, that results of *x*-rays were variable. He asked Dr. Abbe if it were better to attack the thymus first.

Dr. ABBE, in reply to Dr. Miller, said the thymus was removed only in bad cases. With radium and with *x*-rays the gamma rays went through. It was difficult to watch patients and get reliable records, but one generally got results with *x*-ray and with radium. As to operative technique, it was simple. Generally tying of ligatures was enough. It was not advisable to attack the thymus first. This case he considered a glandular hyperplasia. The symptoms sometimes subsided spontaneously. They often followed shock or grief. He had seen them go away spontaneously in young girls.

The Prognostic Significance of Changes in the Retinal Vessels.—Dr. ARNOLD KNAPP read this paper. (See page 883.)

In reply to a question, Dr. Knapp said that the corkscrew character of the smaller vessels observed in the early stages became less marked in the course of the disease. The visible tortuousness of the temporal artery to which Dr. Abbe referred, was a different symptom, as the retinal vessels in which these early changes occurred were only a little larger than capillaries.

Dr. THACHER asked if they straightened out; if so they must shorten. He asked how they shortened.

Dr. KNAPP said the adjustment of the vessel wall caused the change. They shortened probably by the arterial wall becoming rigid. The corkscrew was not so noticeable in advanced cases.

Dr. POTTER said he would like to know if cases had been followed from the corkscrew stage to advanced cases. He would also like to know if the statement of Geiss as to prognosis of apoplexy, so striking in all 17 cases, would coincide with Dr. Knapp's experience. He thought the time was too short. He asked if, in the case of the young man quoted, there were any mental symptoms that showed involvement of the cerebral arteries, and if there was any kidney involvement. Dr. Potter said he had found Dr. Knapp's paper most illuminating and interesting. He thought it was difficult for practitioners to use the ophthalmoscope skillfully, but with training in the modern medical school, most men could use it. He found the finer changes so difficult to determine that he always relied upon an ophthalmologist and took his findings as conclusive. Even when such changes were pointed out to him they were difficult to appreciate. He thought that, unless trained more minutely and constantly, it was difficult for the clinician to see other than advanced changes. Those in young people were very difficult. The interest would largely depend upon what line of work a physician was concerned with, but more time would have to be taken with the average patient, if we were to work with the ophthalmoscope. He said as far as treatment of arteriosclerosis by the private practitioner, suggested by Dr. Knapp, was concerned, there were important points such as avoidance of worry, fatigue, etc., favoring elimination; and bringing the patient's work and routine down to a point suited to an older person; that is, making a person of 40 live like one of 60 years. As far as drugs were concerned, none seemed to be of special therapeutic value. The lack of early diagnosis was noticeable. If they could make a diagnosis 5 or 10 years earlier they could help intelligent patients. He asked Dr. Knapp if his experience of thrombosis was coincident with the percentages quoted. He felt that in cases of chlorosis the prognosis was extremely good. He was obliged to the Society for permitting him to hear this extremely interesting and instructive paper.

Dr. KNAPP said he believed that cerebral complications occurred much earlier than four years. The young man whose case was quoted was a freshman at college, getting on very well in his studies. Malaria and whooping cough were previous illnesses. In regard to percentages, he believed that in his records the percentages of a strictly localized lesion were larger.

Dr. ROBINSON said he, personally, was getting tired of hearing about hardened arteries as being the cause of all sorts of unpleasant manifestations. In many cases these were a protection to the individual. He did not believe in making sudden changes in the habits of healthy individuals simply because of high blood pressure. People felt well till they had their blood pressure taken.

Dr. BRANNAN said he appreciated Dr. Knapp's paper as they had been told so much in a few words. He was not sure what he meant when he said the general practitioner did not pay sufficient attention to vascular conditions. If anything, too much was paid, whether blood pressure was high or low. The insurance companies made such a point of blood pressure that some physicians made a practice of influencing it. As to treatment of arteriosclerosis—diet, exercise and hygienic mode of life gave the best results.

Dr. MEARA said that he had enjoyed Dr. Knapp's paper both in anticipation and participation. He was particularly interested in the first case of a young man who showed the early changes of the retinal arteries with no evidences of cardiac or renal involvement and in whom, two years later, nephritic changes were in evidence. He said that he had been accustomed to look upon this condition only as the expression of toxic changes in the whole cardiovascular system, with maximal incidence upon one or the other territories of this system, that gave the clinical picture to the disease; that is, if the kidneys were specially

affected one spoke of nephritis, if the heart, myocarditis, if there were vascular accidents, one spoke of arteriosclerosis. It seemed to him that in any case of cardiovascular disease it was one's duty to seek for the agent concerned in the changes and that while it was impossible to obtain results in many instances, still in some it would be found on the investigation of the blood that there was an excessive uric acid content, bespeaking a gouty state, responsible for renal or vascular disease; or that there was a focus of infection latent in some remote part of the body, tonsil, teeth, sinus, and so forth. He agreed with Dr. Potter with reference to therapeutic procedure, which was rest for the vascular system, and had felt that muscular effort was less responsible than mental effort and most important of all was the strain put upon the organs by the ordinary metabolic functions. The intake of food should be the minimum compatible with the physiological need. In his experience most gratifying results had followed upon the reduction of nitrogenous intake, salt intake and fluid. He called attention to the Pemberton treatment of arthritic changes by the reduction of proteid, carbohydrate and total calories, as finding the way possibly to the proper treatment of these cardiovascular changes. Opie stated that in the degeneration of the liver produced by chloroform or phosphorus, increase of nitrogen accelerated the degenerative changes, while the intake of carbohydrate greatly reduced them, acting almost as an antitoxin. Thus something could be done for the patient without the use of drugs. Dr. Meara had been much interested in Stengle's report of a group of cases of hypertension, occurring in people of middle life and robust habit, in whom the blood pressure was exceedingly high, and in whom there was a great paucity of symptoms referrable to the kidney. These cases gave a better prognosis than one had been willing heretofore to grant them on the assumption that they were expression of renal change. He knew very little about the ophthalmoscopic findings of these cases. He thought it would be an interesting study to investigate them. He believed that the ophthalmoscope should be used by the internist in the routine examination. He recalled the case of a girl, of 27, whom he went over very carefully and found no cardiovascular changes. The urine had not yet been examined; the ophthalmoscope, however, showed profound changes; the urine later was reported as showing slight changes. The ophthalmoscopic findings often gave the earliest diagnosis of cases of renal disease. He would like to ask Dr. Knapp how he differentiated the eye changes in diabetes, and the eye changes in cardiovascular disease. Dr. Knapp had stated that in diabetes there were characteristic hemorrhages and exudations which were not present in cardiovascular changes.

In answer to Dr. Meara Dr. KNAPP said that in diabetes there were hemorrhages and whitish spots in the retina; the latter were not present in cardiovascular changes. The shape of the hemorrhages depended upon the layer of the retina in which they took place.

Dr. PARK said he was very much interested in this presentation. He would ask one question, that was whether Dr. Knapp would not rather limit ophthalmoscopic work to men whose cases brought them in touch with it. A good many men might thus learn to understand the reports better when they saw them. The average man had not time to keep up these things. Most men depended upon the specialist.

Dr. KNAPP said he agreed with Dr. Park, but he thought the internist ought to be able to appreciate changes in the condition of the retina; the case would then be of much more interest and he could help the patient much better to change his mode of life in time to prevent serious vascular changes.

Dr. MILLER said he was a tyro in the use of the ophthalmoscope, but for 5 or 6 years he had made a routine examination of all cases together with Dr. Norrie, and it had added tremendously to the interest of the service. Gradually a man came to recognize the changes and to appreciate minor points. It was surprising what a help it was to internal medicine. They had a consulting ophthalmologist to check up Dr. Norrie's findings. It was only a question of practice. The corkscrew changes in the vessels were interesting. A neurologist who looked at the eyes with these changes had said that they were often due to syphilis. In some cases there seemed to be a positive ground for this statement, as the Wassermann bore it out, but not always. As regards the general question, the Commissioner of Health had planned an active educational campaign against arteriosclerosis. Dr. Huddleston and he had been over the matter and they had received some interesting contributions which showed there was beginning to be a literature on the subject. The matter of modifying diet in cases which showed beginning changes, and changing the protein intake would add considerably to health and efficiency in many cases. Interest was certainly aroused, but was not perhaps always well directed.

Dr. KNAPP said that changes due to syphilis were of a very different character. The syphilitic process was a round celled infiltration in the coats of the vessel, a perivaseulitis with exudation in the walls.

Dr. ROPER asked Dr. Knapp if examination of the eyes could afford any help in the cases of growing children with nephritis. He had seen cases of young boys, 14 and 16 years, with urinary symptoms of parenchymatous nephritis, but no changes in heart or blood pressure. Could one gather any warning from the retina in those cases. It was hard to exclude such cases from taking part with other boys in ordinary affairs. They were doing well, yet albumin and casts were constantly present.

Dr. KNAPP said that albuminuric retinitis was a terminal stage, not an early one. If the patients were holding their own, the retina would show no change.

Dr. THACHER asked if one could not sometimes find, from arteriosclerotic changes, without nephritis, an appearance similar to albuminuric retinitis.

Dr. KNAPP said in two instances one might get this appearance, one in choked dises after croup, secondly in brain conditions.

Dr. THACHER said that sometimes an ophthalmoscopic picture very like that of albuminuric retinitis was found, where there was marked arteriosclerotic change, and very little evidence of nephritis.

Dr. KNAPP said he had not seen that.

Dr. THACHER asked if there was in some cases evidence in the ophthalmoscopic picture of temporary obscuration followed by thrombosis as the result of spasm.

Dr. KNAPP said in a great many cases in which the artery became obliterated the patient gave a preliminary story of temporary obscuration.

Dr. THACHER said he had watched similar phenomena in brain conditions.

Dr. KNAPP said that it must be identical, as the vessels were of the same kind.

Dr. THACHER said he thought the use of the ophthalmoscope by the intelligent practitioner would stimulate his interest and make the reports of the specialist more intelligible to him.

Dr. KNAPP said the question was of great interest to him because it was difficult to treat these cases. The condition was in the eye. The patients did not notice slight swelling of the ankles, or headache. They came to have their eyesight treated. They went to a medical clinic and drifted back to the ophthalmologist. Fundus cases should be treated in a medical clinic. There was great need for a practitioner as a medical ophthalmologist.

PHILADELPHIA PEDIATRIC SOCIETY.

AT a stated meeting held April 13 Dr. ALICE WELD TALLANT reported "A Case of Hemorrhagic Disease in a Newborn Baby." The child was born at term without complication, and on the third day a hemorrhagic swelling appeared on the neck and one side of the face, gradually increasing and extending to the other side of the face. Smaller areas of extravasation appeared in other situations and there was slight oozing from the cut extremity of the umbilical cord. The temperature pursued an irregularly elevated course. Other measures, including administration of gelatin and of adrenalin solution failing, an ampoule of coagulose was injected in two equal parts, and in a short while the symptoms began to recede and the condition went on to entire recovery. There was no apparent source or channel of infection.

Dr. WILLIAM DRAYTON, JR., exhibited "Two Cases of Pellagra in Children That Had Always Lived in Philadelphia." Both patients were girls about 11 years old. The one was of Italian, the other of American, parentage, and neither had ever been out of the city for more than a day or two at a time. Both came under observation on account of difficulty in locomotion, the gait being ataxic with a suggestion of spasticity. Both presented a roughness of the dorsum of the hands and similar cutaneous changes about the eyes. In both

cases symptoms of the disorder had been present for five or six years. In one the cutaneous lesion had been noticed at the outset on the hands, while in the other there had been attacks of diarrhea. In both the reflexes were increased and slight nystagmic movements of the eyes were present on lateral rotation of the eyes. The Wassermann reaction was negative in each instance.

Dr. THEODORE LEBOUTILLIER presented a communication entitled "Thymic Hypertrophy; Thymus Death, with Report of Cases." He reported several cases of sudden death in children in which post-mortem examination disclosed increase in the size of the thymus gland. In two of these the trachea presented evidences of having been compressed during life. In another case recurrent attacks of laryngeal stridor led to a diagnosis of diphtheria, of which bacteriologic or other evidence, however, was not found, while *x*-ray examination disclosed a shadow indicative of enlargement of the thymus gland. The patient died at a later date of bronchopneumonia, but an autopsy could not be secured. In some of the cases recorded in the literature it is believed that death resulted from compressive asphyxia, while in other instances the fatal issue is to be attributed to metabolic disturbances referable to disordered function of the thymus gland.

Dr. WILLIAM M. LATE COPLIN demonstrated a collection of specimens of thymus glands obtained from children. One of these was a large gland of considerable proportions in all directions and lodged upon the heart. Others, while of considerable superficies, were comparatively thin.

Dr. A. GRAEME MITCHELL presented a communication entitled "Leucocytic Counts During Digestion in Infancy." It was found from a study of fifty bottle-fed infants that the number of leucocytes was extremely variable at different periods after nursing and that reduction in the number of leucocytes in the blood was even more common than increase. Crying and excitement had a tendency to increase the number. Also there were variations apparently related to the time of the day. Accordingly, it was concluded that for comparative purposes studies of the leucocytes in the circulation should be made always at the same time of the day, at the same interval after meals and under otherwise as nearly like conditions as possible.

Dr. MYER SOLIS-COHEN presented a communication entitled "Treatment of Tuberculous Children with Different Varieties of Tuberculins, Sera, and Vaccines." Infinitesimal doses were used, just sufficient to induce a slight favorable reaction. Only those cases were treated with these remedies that did not respond to fresh air and careful feeding alone, and the results were satisfactory in a considerable proportion.

The Reaction of Landau.—J. Golay states that this reaction has been devised as a substitute for the Wassermann test. The new seroreaction is based upon a specific behavior of the blood serum of syphilitics with respect to the halogens, more particularly iodine. Landau at first employed liquid paraffin as the solvent for the iodine, but later he substituted tetrachlormethane. The technique of the reaction is as follows: Into a test-tube 12 mm. in diameter, containing 0.2 c.c. of the suspected serum, there is poured 0.1 c.c. of the reagent consisting of a one per cent. solution of iodine in tetrachlormethane. The tube is left to stand four hours or more. There are then added 0.2 c.c. of a solution of ammonia. If the test is positive the solution is clear and transparent. If the serum is normal the solution is milk-white. The explanation of the cause of this reaction is that there is apparently a special affinity of the syphilitic serum for iodine. Golay, however, does not believe that it will supplant the Wassermann reaction in spite of the greater simplicity in the technique.—*Revue Médicale de la Suisse Romande.*

Visual Symptoms and Spinal Cord Lesions.—A. W. Ormond states that visual symptoms are associated with certain lesions of the spinal cord; that the optic nerve belongs to the second order of neurons, and consists of the axons of the ganglion cells formed within the retina; that the optic nerve is part of the central nervous system and reacts pathologically in the same way as the white matter of the cord, being subject to the same pathological processes; and that when visual lesions are associated with spinal cord disease the posterior columns are usually affected and less frequently the cerebellar tracts.—*Clinical Journal.*

Therapeutic Hints.

An Application for Psoriasis of the Face.—G. T. Jackson notes that ammoniated mercury is the pleasantest and promptest remedy in psoriasis of the scalp and face and can be used in these regions while chrysarobin is used on the rest of the body. An ointment of

℞ Ammoniated mercury, gr. xx.
Calomel, gr. xl.
Petrolatum, ad ℥ j.

is sometimes better than that of the ammoniated mercury by itself. Other mercurial ointments, such as that of the yellow oxide, and a dilute ointment of the nitrate, may be used. Lang has found the bichloride of mercury in collodion in ¼ to ½ per cent. strength a good application. It would probably be an unsafe one in a case of any extent.—"Diseases of the Skin."

Intestinal Antisepsis in the Treatment of Goiter.—F. Messerli reports the favorable results that he has obtained with this method of treatment, which consists in the use of thymol or benzonaphthol, as recommended by MacCarrison, or of salol or creosote. In addition there are administered the following laxative pills:

℞ Aloes, 0.05 gram.
Jalap resin, 0.1 gram.
Rhubarb root, 0.5 gram.

This treatment consists in a mild continuous purgation and intestinal antisepsis. It is based upon the hypothesis of the causation of goiter by intestinal bacteria.—*Revue Médicale de la Suisse Romande.*

Treatment of Burns in Infants.—M. Savariaud has obtained good results with the use of the following ointment in the case of burns in young infants when blistering has already occurred:

℞ Balsam of Peru.
Nitrate of silver, aa 1 gram.
Antipyrine, 5 grams.
Vaseline.
Lanoline, aa 1 gram.

—*Journal de Médecine de Paris.*

Artificial Serum Injections in Alimentary Intoxications in Infants.—Marfan recommends the use of the following:

℞ Sodium chloride, 1 gram.
Citrated caffeine, 0.50 gram.
Distilled water, 1 liter.

Of this solution there are injected hypodermically 10 to 50 cubic centimeters. In alimentary intoxication the injections are given daily for five or six days. In cases of athrepsia the injections are given only for three days.—*Le Nourrisson.*

An Ointment for Parotitis.—A. F. Plicque presents the following formula:

℞ Ichthyol.
Ammonium chloride, āā 3 grams.
Petrolatum, 30 grams.

This should be applied night and morning.—*Journal de Médecine et de Chirurgie Pratiques.*

Irrigations of the Throat in Scarlatina.—A. Baumgartner recommends the use of copious irrigations of the throat with the following solution, night and morning:

℞ Hydrogen peroxide (10 per cent. solution), 20 c.c.
Sodium borate, 0.50 gram.
Spirit of peppermint, 5 grams.
Distilled water, q.s. ad 100 c.c.

—*Bulletin Générale de Thérapeutique.*

CHRONIC DISEASES OF THE HEART, KIDNEYS, AND ARTERIES, FROM THE STANDPOINT OF ETIOLOGY, PREVALENCE, MORTALITY, AND PREVENTION.

A DETAILED PLAN FOR PUBLIC EDUCATION IN A LARGE CITY LOOKING TOWARD THE PREVENTION AND CONTROL OF THESE DISEASES.

By IRA S. WILE, M.D.,

NEW YORK.

Despite the increase of longevity incidental to the progress of civilization, it is noteworthy that certain diseases reflect an increased mortality in proportion to the total number of deaths in any age period as opposed to the decreased mortality noticeable, for example, among the diseases of infancy and childhood. The increased death rate from diseases of the heart, kidneys, and arteries is most prominent among the causes of death which apparently have not been diminished by the sanitary efforts of health officers.

According to the mortality statistics of the United States Department of Census, the death rate from organic heart diseases and endocarditis increased from 123.1 in 1900 to 151.2 per hundred thousand population in 1912. The death rate from nephritis and Bright's disease increased from 89 to 103.1, and deaths from cerebral hemorrhage and apoplexy from 67.5 to 75.7 during the same years and for the same unit of population. This increase of mortality is less evident, but still markedly shown by a consideration of the average mortality rates for five-year periods, as is indicated in the following table:

	Mortality per 100,000 Population	
	1901–1905	1906–1910
Organic diseases of the heart	124.2	13.2
Diseases of arteries, atheroma and aneurysm	9.4	17.7
Bright's disease	87.4	87.4

Considering the relation of these three groups of diseases to the general mortality of New York City for the year 1912, basing our figures upon the same census report, one finds that in New York City the total number of deaths from all causes in 1912 was 73,266, of which number 7,251 were due to organic diseases of the heart, 7,104 to nephritis and Bright's disease, and 2,805 to cerebral hemorrhage and softening. The total number of deaths from these specified causes amounted to 17,150, which approximated 24.8 per cent. of all the deaths in the City of New York during 1912.

In order to determine whether this percentage of total mortality was higher than that existent throughout the United States, a further analysis of the deaths in the registration area is provided. Out of a total number of deaths in the registration area during 1912 of 838,251, organic heart diseases were responsible for 86,175, nephritis 62,267, cerebral hemorrhage 46,797. The total number of deaths from these specified causes amounted to 195,239, or approximately 23.2 per cent. of the total number of deaths of the registration area.

A consideration of this large proportion of the total number of deaths from these specified general causes would lead to the inquiry as to whether this increased relative mortality in New York City as opposed to the rate for the registration area was due to urban conditions. It is found by taking figures from the same source that the total number of deaths during 1912 in cities in the registration states was 414,778, of which 42,373 were due to organic heart diseases, 32,875 to Bright's diseases, and 21,241 to cerebral hemorrhage. The total number 96,489 approximated 23.2 per cent. of the total number of deaths. This is obviously the same as the relative number of deaths from these causes in the entire registration area. In the rural sections of the registration States the total number of deaths was 337,665, constituted in part as follows: Organic heart disease 35,846, Bright's disease 22,195, and cerebral hemorrhage 22,193. The total number of deaths from these specified causes, 80,234, formed 26.7 per cent. of the total number of deaths. It is patent from these figures that the causes of mortality from these various diseases are not particularly centered in cities, but that the reduction of the mortality rate from these three causes must necessarily require attention to the causes similarly existent in rural sections.

Inasmuch as all registration States do not possess the same degree of advancement in matters of sanitation and hygiene, it is only fair to establish the facts with reference to the urban and rural population in New York State. We find that during 1912 in the cities of New York State the total number of deaths was 106,429, to which organic heart diseases contributed 10,602, Bright's disease 9,098, and diseases of the arteries, atheroma and aneurysm, exclusive of embolism and thrombosis, 2,100. The total number of deaths from these three general causes in the cities of New York State during 1912 was 21,800, or approximately 20.5 per cent. of the total mortality. For the same period of time the number of deaths in the rural sections of New York State amounted to 36,179, of which 4,086 were due to organic heart disease, 2,868 to Bright's disease, and 1,115 to diseases of the arteries, atheroma, aneurysm, exclusive of embolism and thrombosis. The total number of deaths in the rural portions of New York State in 1912, therefore, amounted to 8,069, or approximately 22.3 per cent. of the total mortality.

From these figures it is apparent that the mortality rate in New York State from these three general causes was much below the general mortality from these causes in the registration States, both in so far as cities are concerned and the rural sections. It is equally obvious, however, that the 24.8 per cent. of the total deaths in New York City in 1912 is 4.3 per cent. higher than the general average from these causes for all cities in the State, and indeed is higher by 2.5 per cent. than the average for the rural population of New York State. These figures lead one to assume that the proportion of deaths from these three causes in the city of New York is considerably higher than is warranted by its general place in hygiene and sanitation in this country.

While these figures relate entirely to mortality, there are no definite or scientific figures to indicate the prevalence of these diseases in terms of morbidity figures. If one may assume a crude factor that has resulted from the study of invalidity experience, there are approximately two years of illness for each death in the community. This would lead one to believe that the number of individuals suffering from these diseases in New York City during 1912 was over 150,000, in addition to the 73,266 who died from these three general causes. The real meaning of these statistics, however, is tempered by the fact that these three causes are increasingly active as agents of mortality with the increase of age. From the standpoint, therefore, of practical importance, it is imperative to recognize the seriousness of these causes of death at various ages. The following tables will indicate the number of deaths from each of the three general causes during five-year periods from the age of thirty to sixty years, the period of greatest industrial activity.

Organic Heart Disease—Total Number of Deaths in U. S. Registration Area—1912, 86,179.

30-34 Yrs.	35-39 Yrs.	40-44 Yrs.	45-49 Yrs.	50-54 Yrs.	55-59 Yrs.
1987	2935	3615	4376	5871	6613

During these thirty years the total number of deaths was 25,397. In other words, 38.9 per cent. of the total mortality from this disease occurred during these thirty years.

Nephritis and Bright's Disease—Total Number of Deaths in U. S. Registration Area—1912, 62,267.

30-34 Yrs.	35-39 Yrs.	40-44 Yrs.	45-49 Yrs.	50-54 Yrs.	55-59 Yrs.
1982	2858	3562	4210	5429	5685

During these thirty years the total number of deaths was 23,726. In other words, 38.1 per cent. of the total mortality from this disease occurred during these thirty years.

Cerebral Hemorrhage and Softening—Total Number of Deaths in U. S. Registration Area—1912, 45,752.

30-34 Yrs.	35-39 Yrs.	40-44 Yrs.	45-49 Yrs.	50-54 Yrs.	55-59 Yrs.
488	853	1288	2095	3337	4208

During these thirty years the total number of deaths was 12,269. In other words, 26.9 per cent. of the total mortality from this disease occurred during these thirty years.

In order to be certain that the mortality from these three causes during this thirty-year period is above the general average of percental deaths during the thirty-year period, the following table is offered:

All Deaths, All Causes—Total Number of Deaths in U. S. Registration Area—1912, 838,251.

30-34 Yrs.	35-39 Yrs.	40-44 Yrs.	45-49 Yrs.	50-54 Yrs.	55-59 Yrs.
33,743	37,916	37,885	39,624	45,496	45,732

During these thirty years the total number of deaths was 260,396. In other words, 31.1 per cent. of the total mortality from this disease occurred during these thirty years.

It is manifest, therefore, that the percentage of deaths from organic heart disease, nephritis and Bright's disease, and cerebral hemorrhage and softening is far above the general percentage of mortality from all causes during the thirty-year period.

To focus the same inquiry upon conditions in New York City I am presenting similar tables for New York City during the year 1912, using, however, the causes of deaths as applied to the white population. The reason for omitting the colored population is that in the total registration area of the United States the colored population is a more negligible factor than in New York City, owing to the fact that so few Southern States are numbered among the registration States.

New York City—All Deaths, All Causes (White), 1912—70,659.

30-39 Yrs.	40-49 Yrs.	50-59 Yrs.
7249	8404	8741

During these thirty years the total number of deaths was 26,994. In other words, 34 per cent. of the total mortality from all diseases occurred during these thirty years.

New York City—Organic Heart Disease—1912, 7024

30-39 Yrs.	40-49 Yrs.	50-59 Yrs.
553	884	1204

During these thirty years the total number of deaths from this cause was 2,641. In other words, 37.6 per cent. of the total mortality from this disease occurred during these thirty years.

New York City—Nephritis and Bright's Disease—1912, 6871.

30-39 Yrs.	40-49 Yrs.	50-59 Yrs.
645	1112	1494

During these thirty years the total number from these causes was 3,251. In other words, 47.3 per cent. of the total mortality from these diseases occurred during these thirty years.

New York City—Cerebral Hemorrhage and Softening—1912, 2750.

30-39 Yrs.	40-49 Yrs.	50-59 Yrs.
98	241	604

During these thirty years the total number of deaths from these causes was 943. In other words, 34 per cent. of the total mortality from these diseases occurred during these thirty years.

The startling fact is now apparent that in New York City during the thirty-year period these three general diseases caused 34 per cent. of their total deaths, as opposed to 31.1 per cent. in the registration area. Organic heart disease caused 37.6 per cent. of all its deaths, as opposed to 38.9 per cent. in the registration area, while nephritis and Bright's disease yielded 47.3 per cent. of their entire mortality, as opposed to 38.1 per cent. for the registration area, and cerebral hemorrhage and softening caused 34 per cent. of their total mortality in New York City, as opposed to 26.9 per cent. in the registration area.

From this compilation of figures, rather formal in nature, we are brought face to face with the fact that the mortality rate from these three general causes in the City of New York is far higher during the thirty years of greatest industrial productivity than they are for the registration area as a whole. In other words, while a greater mortality from these diseases is to be expected in the decades after sixty years, New York City is suffering a disproportionate loss of human life from these causes during the ages thirty to sixty years.

A recognition of the difficulties of diagnosis makes it imperative to recognize that there are

undoubted errors in the causes of death as reported to registrars of vital statistics. On the other hand, the interrelation of these three diseases is such that the sum total of the mortality may probably be regarded as reasonably accurate.

Diseases of the heart, kidneys, and arteries are very closely interrelated. The diseases of the heart may underly arterial alterations or diseases of the kidneys. Diseases of the kidneys may underly diseases of the heart and cause arterial degenerations; and, in turn, arterial degeneration may cause diseases of either the heart or the kidneys, or both. Finally, diseases of the heart, the kidneys, and the arterial system may all be dependent upon the same underlying cause.

Having recognized, therefore, the mortality and the morbidity of these three diseases, the question arises as to their preventability. The word "preventability" may best be defined in the words of Irving Fisher in the report of the National Conservation Commission on National Vitality: "A 'ratio of preventability' is the fraction of all deaths which would be avoided if knowledge now existing among well-informed men in the medical profession were actually applied in a reasonable way and to a reasonable extent."

While figures for preventability have not been actually determined in a scientific manner, we will assume for the purpose of argument the approximate correctness of the ratios of preventability as established after inquiry by Irving Fisher. From his figures we may quote the following:

Cause of Death	Median Age of Death	Ratio of Preventability
Tuberculosis of lungs	33	75
Septicemia	34	40
Pneumonia	37	45
Acute nephritis	39	30
Pleurisy	42	55
Alcoholism	44	85
Rheumatism	47	10
Chronic poisonings	48	70
Pericarditis	52	10
Dysentery	52	80
Endocarditis	56	25
Diabetes	58	10
Bright's disease	59	40
Venereal diseases		70
Whooping cough		40
Measles		40
Diphtheria		70
Scarlet fever		50
Tonsillitis		45
Typhoid fever		85
Puerperal septicemia		85
Other causes incident to childbirth		50
Diseases of childhood	2–8	67
Diseases of middle age	23–49	49

The ratio of preventability of death from all causes at all ages he places at 42.3 per cent.

It is not necessary at this time to consider the economics of the subject nor, even for the purpose of argument, to show the economic advantage to the community of conserving human life so as to promote communal progress. It is sufficient to realize that it has been estimated that 42.3 per cent. of all deaths belong to the category of those preventable. This in itself is sufficient argument for the necessity of bending all efforts toward the reduction of the morbidity and mortality of diseases of the heart, kidneys, and arteries which has already been shown to cause a disproportionate mortality in the City of New York during the ages of thirty to sixty years.

The reduction of mortality in itself is dependent upon the early recognition of disease. The reduction of the prevalence of disease is totally dependent upon an appreciation and understanding of the etiological factors underlying each specific cause of death. It is needless to comment that the decreasing of a morbidity from these three diseases during the thirty-year period will decrease the absolute mortality during these periods, but need not necessarily decrease the total number of deaths from these causes which will accrue during the senile period of life. All people must die and the great problem is to prolong life in so far as may be possible beyond the Biblical threescore and ten. To decrease the mortality from these diseases need not necessarily decrease the prevalence, as the decrease in mortality might possibly be due to an improvement in therapeutic science which might devise means capable of restoring the sick to normal usefulness. Owing, however, to the very seriousness of these three general causes of death, it is improbable that therapeutics will work wonders in decreasing the mortality for many years to come. It becomes of the utmost importance, therefore, to lay special stress upon those measures which will tend to lessen the prevalence of these diseases.

I have said above that in order to control the prevalence of these diseases, it is absolutely essential to understand their etiology. After a consideration of the etiology of diseases of the heart, blood vessels, and kidneys, I have arranged the following table showing the similarity of the etiological factors underlying the three conditions:

Table of Etiology.

Agents	Heart Diseases	Arteriosclerosis	Renal Diseases
Contagion and infection	1 Pleurisy	1 Infectious diseases (Warfield)	1 Infectious diseases
	2 Pneumonia and typhoid fever	2	2 Pneumonia and typhoid fever
	3 Exanthemata	3	3 Exanthemata
	4 Diphtheria	4	4 Diphtheria
	5 Gonorrhea	5	5 Gonorrhea
	6 Influenza	6	6
	7 Septicemia	7	7 Protracted suppuration
	8 Syphilis	8 Syphilis	8 Syphilis
	9	9 Malaria	9 Malaria
	10	10	10 Phthisis
	11 Tonsillitis	11	11 Tonsillitis
Toxins and poisons	1 Rheumatism and chorea	1 Rheumatism	1 Rheumatism
	2 Alcoholism	2 Alcoholism	2 Alcoholism
	3 Gout	3 Gout	3 Gout
	4	4 Lead poisoning, etc.	4 Lead poisoning, mercury, etc
	5	5 Diabetes	5
	6	6	6 Pregnancy
	7	7	7 Burns
	8 Overeating	8 Overeating	8 Overeating
Physical strain	1 Excessive muscular labor	1	1
	2	2 Muscular overwork	2 Traumatisms
Mental stress		Worry, mental strains	Worry, anxiety and grief
General or undefined	Arteriosclerosis	Exposure	Cold and exposure
	Renal disease	Heart disease	Heart disease
		Renal disease	Arteriosclerosis

A moment's reference to the above analytic table of etiology indicates at once the interdependence of these three general conditions and, in turn, their mutual dependence upon a series of underlying conditions, which in themselves are largely responsible for the mortality directly attributed to the diseases of the kidneys, arteries, and heart. Wherefore, it becomes obvious that in order to lessen the prevalence of diseases of the heart, kidneys, and arteries it is essential for a municipal health department to attack the underlying factors directly, and thus secure indirectly the benefit of a decreased prevalence of them. Obviously, the reduction of the prevalence of the underlying diseases will in itself secure a decrease in both morbidity and mortality during all ages up to the time of life when senile changes are productive of fatal results.

We have thus naturally led to a consideration of our detailed plan looking toward the prevention and control of these three diseases. Summarized briefly, the scheme involves the elaboration of plans for the elimination or control of contagious and infectious diseases, the elimination and control of conditions causing poisonings and intoxications, the supervision and regulation of conditions inducing abnormal physical strains, and the minimizing of mental stress in the community. In connection with this general program, the factor of greatest moment is the development of educational propaganda so that the general public may be enlightened as to the causes of these diseases, the methods of control, and the relation of personal and of industrial and civic hygiene to the general elimination or reduction of the prevalence of these diseases.

A large number of the plans now in vogue in health departments are designed for the elimination and control of contagious and infectious diseases. For this reason, I shall merely state my plan rather categorically and expand only in those instances where I think it is necessary for clarity.

Plans for the Prevention and Control of Contagious and Infectious Diseases.—1. The reporting of all contagious and infectious diseases followed by quarantine and the elimination of contagion bearers, possibly with continued fumigation in cases of scarlet fever and tuberculosis. Notice should be given of the intention of the department to prosecute deliquencies of all physicians failing to observe the regulations.

2. Compulsory vaccination for the limitation of smallpox.

3. Available facilities for antityphoid inoculations.

4. The free administration of diphtheria antitoxin. The extension of information regarding the Schick tests, particularly in institutions, in order to ascertain the nonimmunes in whom active immunity may be established.

5. Continuance or development of laboratory provisions for the examinations for gonococci and the carrying out of the Widal and Wassermann tests.

6. The establishment of special clinics for venereal diseases, tuberculosis, and pertussis. Special brief pamphlets should be prepared for distribution among patients to teach them the essential personal hygiene necessary for cure.

7. The establishment of night clinics in sections of industrial population.

8. The establishment of convalescent homes to which patients might be removed from city hospitals for adequate after care instead of their return to their impoverished homes. During stay at city hospitals specific instructions should be given with reference to hygiene during future years. Internes, nurses, or a social worker should be responsible for such instruction.

9. An extension of hospital facilities for the care of contagious diseases, as measles, scarlet fever, diphtheria, pertussis, and tuberculosis.

10. The continuance of infant milk stations together with the establishment of stations for prenatal care. Herein the infant consultation and classes for mothers should be directed by a doctor and nurse. Home visitation by the nurse is necessary to give direct instruction in the home on the many problems of hygiene relating to infancy, childhood, and adult life.

11. The education, licensing, supervision, and control of midwives.

12. The continuance of medical inspection in the schools and an extension of the work of school nurses. An extension of Little Mother Leagues in cooperation with Board of Education trains future parents into a correct attitude of mind toward civic health and the personal responsibility upon which it rests.

13. General propaganda work for city cleaning, dust control, the abatement of nuisances, and the control of breeding places of flies and mosquitoes.

14. Encouragement of medical inspection of employees. Offering occasional lecturers to employers of large groups of workers who are anxious and willing to be taught how to live so as to prolong their days of activity.

15. The licensing, supervision, and control of public baths.

16. The supervision of babies boarded out.

17. Promulgation of ordinances protecting the food supply, particularly as related to the pasteurization of milk, butter, and cheese, and other milk products. Issuing of special bulletins regarding all eatables and drinkables, including water, when any special danger appears imminent.

Plans for the Prevention and Control of Intoxications and Poisonings.—1. The report of occupational diseases by physicians to be enforced.

2. The extension of cooperation with the State department of factory inspection with a view to eliminating unhealthful working conditions. The publication of rules of health for the guidance of factory workers to be posted in factories throughout the city.

3. The establishment of a city hospital for the treatment of drug habitues.

4. The establishment of inebriate colonies.

5. Extension of the work of food inspection, including drug labeling, the use of preservatives, investigation of food containers. Frequent press notices regarding the prosecutions by the department of violators of the pure food law together with the reasons for such prosecutions in popular terms designed to arouse interest and secure public support.

6. The establishment of municipal dietitians in connection with all institutions under city control.

A Plan for the Prevention and Control of Physical Strains.—1. More thorough physical examinations of children applying for working certificates with the restriction of occupations, in so far as may be possible, in the light of physical handicaps revealed.

2. Encouragement of periodic examination of employees, working, for the purpose of propaganda, through labor unions, the Chamber of Commerce and large employers. Direct appeals, and special pleadings are necessary.

3. Medical inspection of school children with adequate follow-up work. Carefully designed cards for parents fixing their responsibility for remedying the defects noted by the medical inspector, and soliciting and urging home cooperation with the school nurses for the purpose of hastening restoration to a more normal state of being.

4. The encouragement of legislation leading to shorter hours of work for women and children and shorter hours of labor for men in positions requiring unusual muscular strain or undue exposure to severe physical conditions. The compilation of medical, hygienic, and sanitary data to establish facts and form arguments for health legislation. Incidentally the department should be prepared,

through the development of the statistical bureau, to assist students of civic health problems in the acquisition of basic hygienic and sanitary data necessary for legislative progress.

A Plan for the Prevention and Control of Mental Stress.—1. The establishment of homes for incurables so as to lessen the anxiety within the homes now forced to care for them.

2. The encouragement and oversight of day nurseries so as to lessen the anxieties of mothers obliged to enter industry.

3. Interdepartmental cooperation with the department of charities, tenement house department, and other municipal departments with a view to increasing facilities for public employment.

4. The issuance of notices relative to the relation of a high standard of living to public health, the importance of compulsory sickness insurance, and similar legislative enactments designed to lessen mental stress through the provision of funds during periods of disease and disability.

Above and beyond the administrative measures proposed in the above plans is the establishment of health centers at which may be found clinics or consultation places for the well. In other words, the establishment of the preventive work of the health department should be on the basis of disease prevention. The city should be divided into districts each having a health center under a chief responsible to the Commissioner of Health.

In the plan of organization there would be at this health center, a milk station under the supervision of doctors and nurses capable of giving direction and advice in the care of infants and children and prenatal care for expectant mothers. In addition to the doctors and nurses, there should be a practical housekeeper and dietitian. Classes should be organized for mothers with infants and small children, classes for boys and girls of puberty, classes for engaged girls or newlyweds, classes for pregnant women, classes for parents, classes for men. Circulars and pamphlets should be prepared for distribution and lectures given on such subjects as:

Foods and Food Values: The Relation of Foods to Health; Pure Foods—How to Buy; Prepared Foods; How to Prepare Foods; How to Live Cheaply and Well; A Safe Water Supply.

Contagious Diseases: How to Prevent Contagious Diseases; Vaccination—Methods of Prevention—Early Symptoms; Relation of School Nursing System.

Venereal Diseases: Prevention—Social Dangers—Economic Cost.

Sex Education.

Advertised Drugs, Tonics, Quacks; The Hazard of Alcohol.

Abortions: Dangers—Evils; Childbearing and Good Health.

Tuberculosis: Prevention, Control, Home Methods of Treatment.

School: Medical Inspection of School Children; The Problem of Feeding School Children; The Value of School Clinics.

Teeth: The Care of Teeth—Relation of Teeth to Health.

The Home: Ventilation—Bedding; Cleanliness—Control of Vermin; Light and Air; Rights of Privacy.

Milk Supply: Necessity of Pure Milk, etc.; Care of Milk in the Home.

Care of Infants; Feeding of Children at Various Ages.

First Aid to Injured.

Fire Protection: What to Do in Case of Fire; Necessity of Learning Ways of Escape, etc.

The above list of subjects is not meant to be inclusive—but merely slightly suggestive of the scope of the subjects that could be covered at a center of hygiene.

Such lectures as above suggested and many others could be arranged for through a staff of cooperating lecturers who could be recruited from physicians, nurses, social workers and others living within the special districts of the health centers. In each health center there also should be a general medical clinic and such special clinics as are necessary for the elimination and control of preventable diseases. In other words, such a center of hygiene would radiate the doctrines of cheerfulness and health and would serve as educational centers for the general enlightenment of the public with regard to the methods of keeping well.

The location of clinical facilities in the same building is for the purpose of giving every opportunity to the workers to secure restoration to health. As a center of health, it will occupy a peculiar and important place among agencies devoted to civic betterment. A social worker should also be connected with each center, in order that the various social problems relating to general health may be referred to the proper city department or social agency for the necessary remedies. With a serious attempt at the organization of district health centers of this character, it would be possible to coordinate all the social agencies within the district into district advisory councils for the promotion of civic health. The value of a cooperative council plan of this character has been demonstrated in the plan of the Babies' Welfare Association of this city.

The general educational plans which are most essential in any scheme for the elimination or reduction of mortality from diseases of the kidney, heart, and arteries require vigorous and continuous educational propaganda. For the purpose of brevity, I shall merely catalogue with brief comment the various agencies which should be utilized in public health education.

1. The maintenance of a health bulletin to be distributed by mail, to be sent to schools, public libraries, to social and philanthropic agencies.

2. The development of moving picture scenarios so as to present health factors to the eyes of the public. This has been successfully done in the film, "The Man Who Learned," dealing with the pure milk problem.

3. The encouragement of short sketches dealing with health problems for productions at vaudeville houses and aid in writing them.

4. The use of posters on public bill boards.

5. The organization of health exhibits in vacant stores and compact travelling exhibits for loan purposes to schools, shops, factories, churches, and similar institutions. Such exhibits should be of two types, viz.—a general keep well exhibit constructively showing how to live, and special exhibits depicting and illustrating particular health problems as the prevention of tuberculosis—the care of the baby and plotted curves, photographs, cartoons, drawings, papier maché models, and various other appealing forms of exhibit will be required.

6. The maintenance of frequent press notices concerning facts necessary for public health education.

7. The organization of a staff of capable lecturers within the department and the securing of cooperation from the department of lectures of the Board of Education with a view to increasing the number of lectures on health topics to the adult population attending the lectures at public schools. Further, the organization of a volunteer lecture corps to be recruited from public spirited physicians, nurses, etc., interested in public health.

8. The distribution of brief, concise, and to-the-point health talks to parents and industrial workers through the medium of the children of the public schools, the agents of the Metropolitan Life Insurance Company, and the secretaries of organizations, of churches, directors of Y. M. C. A. branches, and organizations such as the Boy Scouts, the Campfire Girls, the State Militia, and other organizations now existent.

9. The establishment of a Health Day to be celebrated by special exercises in schools, churches, etc., dealing with health problems.

10. Active participation in the programs of conferences on charities and corrections to indicate the relation of various social problems to public health.

There are numerous neighborhood associations such as the Gramercy Park Association, the Chelsea Association, the Corlear's Hook Association, etc., which already have organized cooperatively a large number of agencies to consider district problems. It will be possible to utilize existent organizations of this character in connection with the district health centers to the end of focusing in a single health center all the health activities of the district with a common aim and purpose of eliminating unnecessary disease and disability.

The value of such coordinated activity will be manifest in the support which the Health Department will receive in its demand for increased appropriations so necessary for carrying out in any extended form a general plan for the reduction of disease based upon propaganda. Furthermore, the education of public sentiment as to the value and necessity of health education work of this character would result in more vigorous and successful efforts in promoting legislation designed to protect the general public from preventable diseases and disabilities.

Similarly, the establishment of a large working force throughout the city of volunteer workers might render it possible to adopt in part the English plan of having volunteer Health Visitors who without cost to the city, under proper direction and supervision would add very much to the establishment of healthful living conditions.

It may be urged that the plan as thus outlined would be exceedingly expensive. It is doubtful whether the increased cost would be very much per capita. Mr. Edwin Chadwick, at one time secretary of the English Board of Health is quoted by Irving Fisher as saying that a sanitary "engineer ought to contract for the reduction of the sickness and death rate, in such a city as Glasgow, by at least one-third, for a penny a head of the entire population." While these figures may not be applicable to New York City, which now has a 64 cents per capita tax for the activities of the department of health, it is doubtful if the increased expense would be much greater than that suggested by Mr. Chadwick for Glasgow. In estimating the lives of human beings, it is certainly true that it is far less expensive to keep people well than it is to treat them and meet all the costs of their illnesses. While for a few years there might be increased appropriations for the health department, as soon as the results of the health education propaganda are manifest, there would be decreased appropriations for departments of charities and corrections and probably for some phases of the work of the health department itself.

If the slogan of the New York Health Department that health is purchasable be accepted as true, it remains only to convince the public that the cost is not exorbitant in proportion of the returns to be expected. In the general plan for the prevention of diseases of the heart, kidneys, and arteries, it is, therefore, necessary to organize the work of the health department from the standpoint of education in such a way as to attack the entire problem of public health.

In arranging and organizing the work of the public health director, the broadest point of view therefore is necessary, namely, the establishment of plans for the maintenance of the public health on the basis of preventive medicine, while the establishment of conditions for curative measures takes a position of subsidiary importance.

In order that the public moneys may not be wastefully used, it is desirable to try out the proposed plan of the special health center in a single district of the city, so that from an analysis of birth returns and mortality statistics, the actual effect of the health propaganda may be demonstrated.

ECONOMY IN STUDY:

CERTAIN PRACTICAL POINTS, PSYCHOLOGICAL AND PHYSIOLOGICAL, ON HOW TO STUDY TO THE BEST ADVANTAGE.*

By GEORGE VAN NESS DEARBORN, M.D.,

CAMBRIDGE, MASS.

PROFESSOR OF PHYSIOLOGY; AND OF THE PHILOSOPHY OF PHYSICAL EDUCATION IN THE SARGENT SCHOOL.

THE fact must be frankly faced that it is possible that some two or three of you would be more useful to yourselves and to the world in a nice "job," either on the front or on the back end of the street cars; or in a good, substantial position in a machine-shop, in a laundry, or in a confectionery store, or something like that. For it is possible, if not probable, that some of you are not of a scholarly "make-up" at all, so that you never could be a success as physicians. Now is the time to discover it, although a year at anatomy and physiology would in any event be of use to you.

Interest in the Subject.—If you are naturally of a scholarly disposition it is much easier to effectively study than otherwise it could be. But whether scholarly or not you must first have a real interest in that which you wish to study. If you have grown up without the "natural medical interest," it is your duty to acquire an interest in Medicine, but when you have really acquired a real *interest* you will learn almost reflexly and without any great effort on your part because it will be a *pleasure* to you. So this matter is truly worth while. Furthermore, you must have a continually changing and a continually developing interest, not only in Medicine as a whole, as a prospective life-profession, but in-

*Remarks made, for the most part, to the Premedical Class of the Tufts College Medical School, Boston, March 8, 1915.

terest in each of the forty and more subjects as they come along. Some of the essential medical subjects will be most interesting to you and some of them certainly least interesting, but in every case, if you wish to economize and if you want to adequately learn, you will, as a preliminary, develop an interest in the subject you are studying. It was once facetiously claimed by Huxley that he could make a course in osteology interesting to anybody who studied it! It is absolutely necessary, then, in short, to have *interest*, natural or acquired, and if you have not a natural interest you will have to acquire one, or obtain some other form for your continual use!

Some, in fact millions, never go far enough or deep enough to develop an interest—never deep enough to realize how unimaginably marvellous is their world of matter and life and mind. This may be "fate" or it may be just laziness.

The best way to develop an interest in any subject is by *collateral reading*. Read broadly on subjects allied more or less closely to what you are studying. When it is physiology, for example, you should read about related diseases, physics, psychology, and the enticing histology of the nervous system, for examples. There are all sorts of exceedingly interesting material to be got from the libraries which is related to this particular subject, complex and fascinating itself. Another way to develop interest is by *thinking* for yourself of those relations. A third method is to *associate with people* who already have an interest. Fortunate is the student who can have the advantage of association with masters of the subject then in hand. Whatever be the means, you must have interest—by this time you ought to believe this fundamental fact, if reiteration will make you!

Whatever you have an interest in, you *enjoy* doing, and that is the reason why well-adapted work in the long run is the most certain, if not the greatest, of human delights. Many people think of work as a necessary something disagreeable rather than agreeable, but I repeat that it is certainly one of life's most permanent and substantial satisfactions and delights. Unpleasant undeniably is work that is not adapted to the individual. You do not often see professors in our universities and colleges grumbling about their work, and this is not primarily because their work on the whole is pleasant, but more often because it is well adapted to them; for else they give it up. It is the vast body of men who do not as yet have work which is adapted to them who do not like to work. All great, useful, and original work ordinarily is done under conditions such that the work is enjoyable, there being always enough of interest about it to make it pleasureable. It is under these conditions, furthermore, and generally under these alone, that the largest amount of energy is expended. This basal relationship is expressed in the science of efficiency in the term "Sthen-euphoric Index," meaning, in short, the more or less direct ratio between the expenditure of *energy* in any action and its inherent *pleasantness*. "Enjoy your work and you will most likely expend a very large amount of energy in it." This is the practical corollary of this fundamental index of organic dynamics.

After having a good interest acquired and understood the relations between it, enjoyment, initiative, and energy, we may next consider the learning process proper. There are two kinds of learning as a procedure, one of which is a *conscious* process, conscious, deliberate study; while the second is another mode of learning, of which most of you are not even aware, namely, *subconscious* learning; in short, by observation and association, more or less unconscious.

Conscious or Deliberate Study.—When you think of study most of you, I am sure, consider only conscious, deliberate study, reading, or "grinding" usually in some book or other. This process, as you will understand next year better, is essentially a checking or restraining process, that which we call in physiology and in psychology "inhibition," an incentive of some sort to check some active process by a normal influence. The process of conscious study is one of an inhibitory nature—in its ultimate analysis the essence of humanity and of its civilization and culture—this year so horribly abused!

In the first place you have to inhibit *fatigue*, when you "grind." You are tired and would like to go to bed, or to go outside for a walk, or to some place of amusement that is restful. There should be no fatigue, theoretically. Your work should be so arranged, alternating with rest and exercise and eating, that there should be no appreciable and depressing fatigue. This inhibition of which we are speaking seeks a more *pleasant occupation*. Billy calls around and wishes you to play "old maid" or something or other; or Cousin Susie wants you to go to the movies with her. Then there are many *distractions* which have to be inhibited: the reckless automobiles or carting on the avenue, cats or hyenas on the back fence, a piano-torture from the next room, or someone beyond all humanity trying to play on the violin. All sorts of *sensory stimuli* have to be kept out of your effective mind. The *desire to change* must be inhibited, the perfectly normal tendency to change your occupation and thus get rested.

Study, then, so far as deliberate, is the forcing of the mental processes along new pathways, the forcing of nerve-impulses perhaps through groups of thousands of neurones where exactly they have not been before. When interest is acquired and other things are right and you are in good physiological condition, it is a real pleasure to truly grind. The habit of even this kind of study is easily acquired, much more easily in most of you than you think. Even the habit of inhibitory, forceful grinding on difficult study-subjects is soon acquired if you give yourself a fair chance to acquire it; and knowledge and understanding will represent the comfort of your wives and children for they will largely be your earning capital.

Beware of *false study*, dozing: trying to hold your eyes open while your brain is shut tight. In such cases your brains are not open, for the sensory paths and the association paths are closed. If your interest or attention cannot be forced on what you are studying, you should wholly rest for a few minutes or else open the windows, stir about, and force the issue! Or, if conditions are such that you cannot possibly give your attention to your subject, as in fatigue readily may happen, give it up. Unless you give your whole attention to whatever you are studying it is of little or of no account to you, and much worse than that, it gets you into the bad habit of sitting with a book in front of you and pretending to yourself (and sometimes to your teachers) that you are studying when in reality your brain-neurones are not getting hold on the facts at all. The loss of a little time is of no account compared with the misfortune of this habit.

There should be *no rote-learning*. There are only extremely few things tnat are properly learned by rote, and it is well to avoid attempting to learn in this way. In the long run it is a great waste, and therefore I suggest that you do not get into this habit either. No lecturer or quiz-master who knows his pedagogical business will give out his material or opinions so that you can take it down in the form of formulæ and "run it in" on an examination or elsewhere. A lecture should be, almost always, explanation and not description; lectures are properly complementary to texts. Facts and principles should be learned by concept, not by word.

There are certain physiological requisites for study, especially five things of a hygienic physiological nature which must be mentioned: namely (1) good health, (2) abundant outdoor muscular exercise, (3) abundant natural air, (4) abundant proper food, and (5) abundant sleep.

It is necessary for a student to have *good health*, else he is inexcusably wasteful. One cannot possibly study, for example, with *eye-strain*, for this inflicts a continuous strain on the brain and on the whole nervous system, which depresses the vigor of the mental action. Students should not think of studying when they have a *headache*, in which condition the brain is congested with blood. Under such circumstances it would be more economical to take a brisk, erect, longish walk out of doors, or to do almost anything except study. For a like reason, one should not try to study when he is *ill*, say with a bad cold in the head, even a mild influenza, or anything of that sort. Some try to study when they are at home "sick," which is absurd, unless it is a broken leg or something of that non-neural nature. It is very necessary that a successful student should be *free from worry*.* Don't stay a student and allow yourself to worry about the family skeleton, illness in the home, or other things even though they be of such real importance. If worrying interferes with your business of studying, either give up worrying or postpone your business, for certainly you cannot do both at the same time. In some cases study can be made to force the worry out of your head; if so, it is well.

Take *abundant gross muscular exercise*. The reason for this is that exercise stimulates the circulation, and "keeps the cobwebs out of the brain," the spinal cord, and other important nerve-masses. Muscles, as well as brains, are used in thinking, and they don't work as well when they are flabby and out of tone, and poorly supplied with oxygen and clogged with carbon dioxide. Too much exercise, on the other hand, must be avoided, since it employs the brain and so tires it beyond use for study.

Abundant Natural Outdoor Air.—It is not necessary to study out of doors, as you can have plenty of outdoor air indoors by the simple expedient of opening the windows. Air of the proper temperature and proper humidity is essential. Moving air, properly moist and properly *cool* (68° F.), is the ideal.†

Have *abundant food*, but not too much. The ideal is food that is easily digestible and taken often. Four moderate meals a day is far better for a student than two over-large. Coffee may be taken if necessary for successful study. There are many authors who do good and abundant creative work under the influence in general only of tea or of coffee, essentially alike in their stimulant action. I do not suggest alcohol, for it is a poisonous depressant and not a stimulant at all, save indirectly on the heart.

Students to be efficient must have *abundant sleep*. Ten hours is little too much. There must be no study within an hour, at least, after eating. Gentle ambulatory exercise helps digestion, on the other hand. It is certain that if the blood is in the stomach doing its work there, enough of it cannot be at the same time in the brain, and your brain cannot work without its normal abundance of blood. So that it is quite absurd to think of studying to good advantage immediately after a hearty meal. It is by many considered a good thing at times through the day to take cat-naps. Food digests best of all when you are asleep. Do not try to carry on your work on the boa constrictor plan of taking one big meal every six months and then going to sleep for the next six months! The boa constrictor is a poor student. Ten hours sleep is none too much and cat-naps certainly are excellent, for a short nap, even of five or ten minutes, gives one a large amount of cerebral rest, for even a five-minute nap takes the blood for a moment out of the brain, stirs things up there generally, and makes one ready for a good siege of study.

Attention to a book should *not* be *too long concentrated*, without pause. It should by habit be concentrated vigorously, but only for relatively short periods at a time. There should be more power of concentration for short periods than most high-schools inculcate, but one cannot keep his mind strongly concentrated for long periods under ordinary degree of educational interest. Every twenty minutes or so you should walk around the room for a minute or two, for this activity draws some of the blood out of your brains into your legs; moreover, it relieves the injurious long fixation of the eyes. No one can sit for an hour, or an hour and a half, without changing his position, except at a considable loss of nerve-economy, and it is under such a condition naturally difficult to avoid going to sleep, partial or complete.

Grammar schools and high schools almost never as yet succeed in teaching their students *how to think*, and yet that is what counts most. A momentary, thoughtful idea often is worth a week of fruitless mechanical grind, just as one large highly-cultivated Gravenstein is worth a whole barrel of crab-apples. Quality not quantity is what counts in study as well as in other things. Make a serious business of it, then, when you study, remembering that real learning, that is understanding and constructive power, comes only through thought.

Subconscious Learning.—This is a mode of learning which one unfamiliar with psychology is not apt to think of as "study" at all. You require this kind of learning (both as process and as product) with your subconscious minds, physiologically chiefly, the association of millions of neurones. Subconscious observation by your subconscious minds would be a common way to characterize it.

A good example of this kind of study or learning is a child about two years old learning to speak. The child, of course, does not at first consciously strive to pick up the marvellous art of speaking, but none the less he acquires it quickly, in part by imitation.

*See, for the therapeutics of worry and nerve-waste in general, a little monograph called "Nerve-Waste," Health Education League Booklet, No. 27, Boston, 1912.

†For a discussion of the need of moving air and of other hygienic conditions, see the lecturer's "Certain Further Factors in the Physiology of Euphoria," "*Psychological Review*," XXI, 3, May, 1914, 166-188, illustrated.

You cannot understand anything worth learning without this factor of mind, the subconscious mind, the great integrator of intelligence. The endless details of knowledge are supplied very largely by this unconscious mental process, this continual subconscious perception and observation by all the senses at once.

It is beyond our present range to describe this phase of the human mind, that deep and on-rushing part of "the stream of consciousness," which is closest to the nervous integrators of protoplasmic function. It is the great planner of our behavior, however, the chief solver of our most important problems in the conduct of life; it is the seat of our motives, the developer of our habits, the associator of our ideas into real and useful knowledge. I recommend it to you for study, that you may understand your own self and the minds of those about you, your future patients especially. (Von Hartmann, Dubois, H. Poincaré, Morton Prince, Ribot, Janet, will teach you about it, all that you need to know, until you observe its phenomena first hand for yourselves.)

At present we are concerned with the subconscious as the chief active recipient of information from the environment and as the chief arranger, developer, and increaser of this ever-varying multitude of educational impressions. As has been said already, without the subconscious there could be no real understanding of actual conditions of experience at all, so myriad are they and so complex and interinvolved.

Keep all your senses open, therefore, to "light" of every kind imaginable which the subconscious integrating process may relate to each other and to yourself, and make you truly *wise*.

There are three chief ways of studying in this process of collegiate learning. In the first place, by more or less conscious *seeing* and observing of books, diagrams, pictures, and other things that you can get only through your sense of vision. Second, *hearing* things with your ears, such as lectures, recitations, and talk. And third, by actually actively *doing* things—extensive laboratory work, clinical work, and to a much less extent essay-work, constructive drawing, research. To discuss these within the hour is out of the question, so that we must be content with the mere observation, although of basal and vast importance, that *doing*, as opposed to receiving, represents the modern method of learning even the most abstract of subjects. The world is becoming aware, and effectively aware, that bodily efficiency one way or another is the basis of learning, or, in the words of wise old Pestalozzi, "Keine Kentnisse ohne Fertigkeiten!"—that is, No knowledge without skill.

Imagination is essential in every scientific man who is more than a manikin. But *visualizing imagination* is of immediate necessity to every student and especially to the student of any individual branch of biology. You must be able to look, in your minds, directly into any part of a living organism and accurately see just what there is and precisely what is going on there. The lack of this power, I am convinced, is the cause of the inefficiency of many physicians. Anatomy, histology, physiology, pathology, clinical surgery, clinical medicine are but impractical knowledge without this faculty, easily developed (by most students) by a little practice. I recommend it to you as an important accomplishment as well as a valuable means of study.

The taking of notes is of sufficient importance practically to warrant a few minutes of discussion. If textbooks are the meat of the student, his notes are certainly his necessary drink, with his meals and at other times. It has been said that one "should train their powers of observation and memory" so as to be able to go into a lecture room and get the gist of the lecture without taking notes. But in the first place, we cannot develop our memory.* Born with a certain kind and perfection of memory we cannot increase its effective span. Do not attempt to accustom yourselves to this, for not one per cent. of you would succeed rather than fail. Every lecture in a professional school contains many material facts, and sometimes hundreds of them, and there is no mind that can remember them all, *economically*. No matter how vital and permanent they may seem the moment when you hear them, they probably are soon replaced with others equally interesting, and very soon most of them are gone, many of them for good, while part of those which remain are jumbled and mistaken.

Take notes of everything worth noting. No matter where you are, whenever you hear anything, or even see anything worth noting, "make a note of it." These notes will be of value to you all your life, the most vital links of your mind with your precious college life; and often of great practical use.

Notes should be schematically arranged in a psychologically scientific way, with center headings, side headings, group headings, and subgroup headings, and put down according to *ideas* under such headings. When all run together notes are not of much use. Let a book's elaborate analytical table of contents be a model for this. One should get into the habit of using abbreviations. Shorthand is very desirable, economical, and almost necessary, but if you cannot manage to learn shorthand,† acquire a system of abbreviation of your device. Do not expect, as I have said already, to get from a lecture anything that you can take down and run in verbatim on an examination, for a good lecture is an explanation, not dictation, not a description, and not a set of crib notes.

It is extremely important to economy that you should keep your notes "posted up" every day, not only in your notebooks, but in your brains. Go over your notes in general every night and connect them with what has gone before, and so keep your mind up with the subject. *Examinations will take care of themselves* if you keep your didactic material posted up day after day. Examinations are not intended to trap you, but are intended as means to find out how much you know or do not know; mostly, in fact, how much you do *not* know. Cramming for an examination is like carrying weights in your pockets when getting weighed: you are cheating yourselves. The economical way is to keep your notes posted up in your books and in your brains every day; so, they can associate and you learn much faster, giving your subconscious faculties a better chance. The power of grasping *ideas* is an extremely valuable one. Pick out the gist and sense of a running discourse, select the ideas and express them in your own words.

The drawing and writing of diagrams is of the

*For an up-to-date brief account of memory see the article in a leading medical encyclopedia, the "*Reference Handbook of the Medical Sciences*," third edition, volume six.

†For the stenography, etc., of this lecture I am indebted to Mr. Ernest Moore Gould, of the Dental Freshman class.

greatest importance, and all put before you should be quickly sketched. The drawing of original diagrams is of much value to you, but the quick copying of those put before you is also very important. Things should not "go in one ear and out the other": there should be something within, between, them to fix the ideas, namely, your brains, and one easy way to do that is writing tersely the ideas, and drawing the diagrams whenever possible. You should, as has been said, learn to visualize, to see things in your mind, and this selection of the essentials will help this important habit.

Frequent reviewing is of the greatest importance. It tends to integrate things, keeps subjects unified, and puts the whole subject before you at once; without a wholeness nothing is of much account.

You should have *as large a variety of textbooks* as you can possibly afford on every subject you study, for, in that way, you get different points of view of the same topic and fixation is more certain. Every ten dollars paid for good books while you are a student will be worth a hundred dollars to you later on. And no wise person sells his old textbooks, for each one has associations with his mind which make it often far more valuable and convenient to him in later years than a new one could be.

Conversation and discussion among yourselves are extremely important as means to accurate and broad information. Talk things over. Collateral reading always lends interest, and makes you a better talker, which in itself is well worth while in a professional man or woman.

Finally, I will suggest that it is a great waste for you to live out of town so that you are obliged to ride for more than half an hour twice daily in the train or street cars. If you figure up this time at the lowest valuation you will find it is actually economical to live near the college, even if your parents furnish living at home. Considering all matters, cash, nerve wear-and-tear, danger, eye-strain, etc., is is certainly economy to live in town and pay board and lodging rather than at home if it be more than, say, twenty miles away. This, like the other matters I have so inadequately suggested to you during the hour, I personally think are worth considering. For the race is keen.

THE MEDICINE OF THE OLD TESTAMENT.*

By STUART B. BLAKELY, M.D.,

BINGHAMTON, N. Y.

In a study of the medicine of the Old Testament two points must be kept always clearly in mind: (1) It is a study of the non-medical literature of a primitive, nomad race. (2) References to disease and medical subjects are dark and incomplete. Careful study of the original Hebrew words themselves has been of little service. Most of the diseases described are either those of kings or personages of high estate or epidemics. If we realize that little is absolutely sure, that much must be inferred, and if we recognize the difficulties of the problems we shall not be led far astray in a medical survey of the Old Testament.

The scriptural references given in this article by no means exhaust the possibilities of the text.

The medicine of the ancient Hebrews was partly of Egyptian, partly of Assyrian and Babylonian origin with, in later times, a possible trace of Greek influence. The medicine of Egypt was famous in its time throughout the East. Cyrus and Darius both summoned physicians from that country. Many of the physicians at the courts of the kings of Israel were probably Egyptian. The learning and culture of Assyria and Babylonia reached flood mark. The ancient Hebrews acquired their medicine during the sojourn in Egypt, by intercourse with other nations, especially during the reign of Solomon, and during the captivities. But the Hebrews were never scientists. They had no scientific institutions. Their science and their medicine were borrowed and empirical. To their minds Jehovah was the highest authority in all things. Jehovah was the Supreme Healer. (Ex. 15, 26; Dt. 32, 39; Ps. 6, 2; 30, 2; 103, 3; Is. 30, 26.) Injury disease, and death were usually regarded as expressions of his wrath, as direct results of his omnipotent will. As a consequence of this belief we find little or nothing in the Old Testament concerning the cause, the course, or the curing of disease. Disease was often looked upon as a direct punishment for sin, a belief prevalent among primitive folk. Threats of disease for sin and disobedience and promises of protection against disease are very common. (Ex. 15, 26; Nu. 14, 12; Dt. 7, 15; 28, 59-62; 32, 39; II Sa. 24, 16; II K. 19, 35; II Ch. 21, 14; Job 2, 5-7; Is. 58, 8.)

Among most early peoples medicine has been at first the property of the priesthood alone. Among the Hebrews, however, the medical work of the priests seems to have been that of a sanitary police —observing, isolating, and disinfecting. Their duties seem to have been always distinct from those of the physicians. (Gn. 50, 2; Ex. 21, 19; II K. 8, 29; II Ch. 16, 12; Job 13, 4; Jer. 8, 22.) The physicians gathered and prepared their materia medica, prescribed for symptoms of disease and treated wounds. The word "physician" in Jer. 8, 22, is literally "a bandager." Many are said to have established themselves east of the Jordan. There are two references to definite consultations with physicians—Asa to be cured of the disease of his feet and Joram to be healed of his wounds. (II Ch. 16, 12; II K. 8 and 9.) The profession was not so highly nor so strictly specialized as among the Egyptians—*cf.* the corps of physicians in the service of Joseph. (Gn. 50, 2.) It was usually held in high esteem, but Asa was reproached because "in his disease he sought not to the Lord but to the physicians." The author of the apocryphal book of Ecclesiasticus is thought to have been a physician. The prophets Abijah, Elijah, Elisha and Isaiah, by virtue of what we call their miracles, may be classed among the healers of the Hebrews. Midwives followed their calling as they do to-day. (Ex. 1, 15-21.) Their duties were of the simplest. They received the baby, cut and tied the cord, washed the child, rubbed it with salt and wrapped it in swaddling clothes. (Ezk. 16, 4.) It has been suggested that the two mentioned by name in Ex. 1, 15, were the heads of corporations or societies of midwives. Such a thing as a hospital was unknown; the sick, except the lepers and probably the "unclean," were cared for in their homes. (Lv. 13, 46; Nu. 5, 2; II Ch. 26, 21.) The dead were burned, buried or placed in sepulchres. The Hebrews did not embalm. Their mind had no sympathy with the Egytian idea that originated the custom. Jacob and Joseph were embalmed only to preserve their bodies until burial could take

*Read before the Men's Forum of the First Congregational Church, at Binghamton, N. Y., November 8, 1914.

place. Among the Egyptians the art of embalming formed a special branch of medicine. The process varied, not only according to the wealth and rank of the deceased, but also at different times in Egyptian history.

It might be interesting to glance briefly at the ancient Hebrews' ideas of anatomy. It is possible that dissection of the human body for scientific purposes had already been done at that early date, but in any knowledge thus obtained the Jewish slaves could have had no share. The Hebrews had no medical schools, no system of medical education. What little true anatomical knowledge they possessed of the internal organs was derived from injuries, war, and the slaughter of animals. All else was tradition or speculation. There are references to the heart, the liver, and the bile or gall, the diaphragm—"the caul above the liver" (Ex. 29, 13), the kidneys, the intestines and the internal fat, and the womb or matrix. The liver was evidently of value in divination. (Ezk. 21, 21.) Certain verses of Proverbs and Ecclesiastes have been cited as proof of Solomon's knowledge of anatomy and the healing art. Traces of a rude conception of embryology are found. (Job 10, 10; Ps. 139, 13-16; Eccl. 11, 5.) Blood to them was life, therefore sacred, and together with the internal fat must be returned to God before the flesh was eaten. (Gn. 9, 4; Lv. 7, 23-27; 17, 10-14; 19, 26; Dt. 12, 23.) They knew that dreams originated from inside the head. (Dan. 4, 5, 13; 7, 1.) The liver was the source of happiness; in several places in the Psalms it is called the "glory." (Ps. 16, 9; 30, 12; 57, 8; 108, 1.) The navel was the seat of health, the heart the source of emotion and of mental and moral activity, the reins or kidneys the seat of desire and determination, the bowels the place of affection and sympathy. We still preserve many of these ideas as figures of speech, but the Hebrews believed them to be truths. The books of Job, Proverbs, and Ecclesiastes contain a curious store of medical lore.

Palestine was probably healthier than Egypt. In the latter country the valley of the Nile was flooded every year, creating conditions favorable for the development of disease. The plagues of the Egyptians were closely associated with the rising of the Nile and with other well known climatic conditions of the country. Palestine, on the other hand, was isolated by land and sea. Communication with it was difficult. Disease was not apt to be carried to it. The land was dry and sanitation was good. There was no overcrowding and no poverty. Under the leadership of Moses, a priest from the temple of the Sun at Heliopolis, the Hebrews became the founders of public hygiene. In Leviticus and Deuteronomy are very definite rules and regulations regarding food, clean and unclean things, sexual hygiene, personal purifications, and contagious diseases. In Ex. 21, 22, and Lv. 24, are found traces of a medical jurisprudence.

We cannot enter into a discussion of the sanitary code of the Hebrews; neither will we describe practices that became religious rites, *e.g.* circumcision. We can only speak briefly of the drugs and methods used in treatment and call attention to some of the diseases and diseased conditions mentioned in the Old Testament text.

The ancient Hebrews had many medicines. (Jer. 46, 11.) We hear of no specifics. The following were some of their therapeutic agents: leaves of trees (Ezk. 47, 12), olive oil, balm of Gilead, a famous resinous application for pain and wounds, and a valuable article of commerce, fig plasters, oil and wine for wounds. The mandrake root was used for barrenness, following the old doctrine of signatures. (Gn. 30, 14-17.) The word translated "gourd" in the last chapter of Jonah is thought by some to mean the castor-oil plant. The personal and ceremonial use of ointments, perfumes, and incense was common, as among all Orientals. These were prepared by the apothecaries and confectioners. (Ex. 30, 25; 37, 29; Isa. 8, 13; II Ch. 16, 4; Neh. 3, 8; Eccl. 10, 1.) The ingredients were both domestic and imported, and their list is long. Among them were frankincense, myrrh, aloes, calamus, camphire or henna, cassia, cinnamon, galbanum, rue, spicery, saffron, storax and others. The following were more strictly medical in their use, as condiments or carminitives—cassia, cinnamon, coriander, cummin, salt, and probably also anise, mint and mustard. The prescription for the holy anointing oil is given in Ex., 30. Salt was used to harden the skin, nitro and soap to cleanse it. (Jer. 2, 22.) The niter was natron, a mineral alkali; the soap was probably potassium carbonate mixed with oil. Elisha used salt to purify springs of water that were reputed to cause miscarriage and death. (II K. 2, 19-22.) Hyssop seems to have been a substance whose use approached that of an antiseptic. It was probably either the marjoram, or the caper plant. The Psalmist lauds its "purging" powers; it was sprinkled on the doorposts of the Israelites in Egypt and was employed to purify lepers and leprous houses. (Ps. 51, 7; Ex. 12, 22; Lv. 14, 4-7, 49-52.) Mankind still clings tenaciously to the belief that the smoke or vapor from burning incense or other odoriferous substances possess detergent properties. It is possible that Hazael practised hydrotherapy when he dipped a cloth in water and spread it on the face of Benhadad, King of Syria, though it sounds more like murder. (II K. 8, 15.) Mineral and oil baths were sometimes employed. The pool of Siloam possessed healing powers. (Neh. 3, 15; Is. 8, 6.) Hot springs—"mules" are mentioned in Gn. 36, 24. These were probably near the Dead Sea. The water of the Jordan contained sulphur, and was famous for its curative properties, *cf.*, Naaman's leprosy. The wearing of amulets, the use of charms and invocations and the laying on of hands in the presence of disease were common practices then as they are to-day. (II K. 5, 11.) The influence of the state of mind on sickness was clearly recognized—"a merry heart doeth good like a medicine." (Pr. 17, 22.) Some kind of arrow poison was possibly in use, most probably aconite. (Job 6, 4.) The water of gall, or the "water of the poisonous plant," may refer to the poppy. (Jer. 9, 15; 23, 15.) Food poisoning of vegetable origin—possibly colocynth or the bitter cucumber—is mentioned in II K. 4. 38-41, for which Elisha used meal as an antidote. Ptomain or meat poisoning was probably the plague that followed the eating of the quail. (Nu. 11, 31-33.) The Hebrews knew well the action of alcoholic drink. They made wine from honey, dates, grapes and other fruits, and it was sometimes spiced. Certain localities were famed for their product of the vine. The drunkard has been inimitably portrayed in Pr. 23.

As among the Egyptians many remedies were dietary. The ancient Hebrews had an ample and

excellent variety of food: meat, fish, fowl, game, locusts, eggs, butter, milk, cheese, sour milk, meal of various grains, bread, beans, cucumbers, onions, garlic, lentils, herbs, manna, honey, fruits, melons, figs, raisins, grapes, nuts, olive oil, vinegar or sour wine, salt, and condiments. The ancient Hebrews probably had no sugar; honey, manna, and fruit juice decoctions were substitutes. The "sweet cane" of Is. 43, 24, and Jer. 6, 20, was probably the sweet flag or calamus. There is evidence of cannabalism taking place in Old Testament times under stress of circumstances. (Lv. 26, 29; Dt. 28, 53; Jer. 19, 9; Ezk. 5, 10.) This is said to have occurred at the siege of Jerusalem by Nebuchadnezzar and at its destruction by the Romans.

The surgical lore of the Old Testament is very scanty. Knives of flint or metal were used for sacrifice and circumcision, and awls for boring holes in the ears. (Gn. 22, 6; Ex. 4, 25; 21, 6: Jos. 5, 3; Dt. 15, 17.) These procedures, castration and "uncircumcision" were probably the only operations. Inflammatory reaction following operative procedures is recorded in Gn. 34, 25. We hear of no tumors, benign or malignant. Burns must have occurred, but it is interesting and curious that nowhere in the Old Testament is any method given for producing fire. In II Sam. 21, 20, is mention of a giant—born so—with supernumerary digits, six fingers and six toes, twenty-four digits in all. In I Ch. 20, 6, his gigantism is described as hereditary. Moses is thought to have had some defect of speech. (Ex. 4, 10.) Legend says that when a boy he put a live coal into his mouth and burned his tongue, so that he was unable to pronounce the labials. It has been suggested, however, that Moses referred to his lack of practice in the Egyptian language. Lameness and blindness were common then as now. (II. Sa. 5, 6.) Just what happened to Jacob's hip when in his wrestling the angel "touched the hollow of his thigh" we do not know, probably a severe sprain of the hip and thigh or a severe injury to the sciatic nerve. The "sinew that shrank" was probably this nerve trunk or possibly an atrophied muscle. (Gn. 32.) Saul's grandson was lame in both his feet, due to his nurse having let him fall when he was five years old, a common history of lameness to this day. (II Sa. 4, 4; 9, 13.) Bone disease existed. Lv. 21, 18-20; Pr. 14, 30.) A crooked back is often due to tuberculosis of the spine, and this was one of the physical blemishes that barred a man from the priesthood. Dislocations were known. (Job 31, 22.) There are possible references to fracture of the skull. (Jdg. 9, 53; II K. 1, 2.) Eli fractured his neck by a fall backward from his seat on hearing the news of the death of his sons and the capture of the ark. (I Sa. 4, 18.) Fractures of the long bones were put up in splints. (Ezk. 30, 21.) There are three references to penetrating wounds of the chest, and three to penetrating wounds of the abdomen. (II Sa. 4, 6; 18, 14; II K. 9, 24; Nu. 25, 8; Jdg. 3, 21-22; II Sa. 20, 10.) There are battle wounds and infected wounds. (I K. 22, 35; Ps. 38, 5.) No method is given for stopping hemorrhage. Wounds were washed, the edges drawn together and bound up in oil and wine. (Is. 1, 6.) There is a possible reference to leeches. (Pr. 30, 15.) The pathology of Pr. 20, 30 is very obscure. There is a suicide by hanging, another by the burning down of a palace, and King Saul fell upon his sword. Abimelech would have committed suicide had he been able.

Without question the common diseases of to-day existed in Old Testament times. In Lv. 26, 16, and Dt. 28, 22, there are possible references to such diseases as tuberculosis, typhoid, malaria, Malta fever, and smallpox. "The pestilence that walketh in darkness" suggests malaria. (Ps. 91, 6.) Certain conditions were termed incurable. There are possible references to affections of the heart. Men were gray haired and bald then as now. Diabetes is comparatively common among modern Jews, but no evidence is found of its existence among the ancient Hebrews. Scurvy almost surely prevailed during their desert wanderings. We do not know what was the "botch of Egypt"—possibly smallpox. (Dt. 28, 27 and 35.) Liver disorders and bowel disturbances were known. The latter are said to have been most common among the priests, because they went about so much in their bare feet on the cold floors of the temple. (Job 16, 13; Pr. 7, 23; Is. 16, 11; Jer. 4, 19.) The Hebrews knew that some disease was contagious, and they recognized the results of a fever. (Jer. 9, 21; Dt. 28, 22.) Beyond that they could not go. But we must not forget that the exact differentiation of most fevers has been made within the memory of men still living.

Of all diseases of Bible times and lands leprosy has always aroused the greatest interest. It was the most important and best known, was endemic in the land, and was considered infectious, contagious and even hereditary. Without question some, possibly much of the leprosy—so called—of the Bible, as well as that of the Middle Ages, was not leprosy at all. The term was applied to any rough, scaly skin condition. As a natural result leprosy was confused with syphilis and tuberculosis, and was often not differentiated from such skin diseases as eczema, ringworm and psoriasis. Leprosy, or at least scaly skin conditions, were common in Old Testament times. Lv. 13 shows the result of keen observation of the disease. The leprosy of garments and of houses was probably moulds or fungi (Lv. 13 and 14). As far as the writer can learn, the following are the only cases cited as leprosy in the Old Testament: (1) the hand of Moses becoming leprous (Ex. 4, 6); (2) Miriam becoming a leper (Nu. 12, 10); (3) the four leprous men before the gates of Samaria (II K. 7); (4) Naaman's leprosy and its transference to Gahazi (II K. 5); (5) the leprosy of King Uzziah (Azariah) (II Ch. 26, 19; II K. 15, 5.) Five references in all. Some palpably could not have been true leprosy. The subject is too big to enter into any further detail.

The plague is one of the oldest diseases of mankind. It existed centuries before Christ. It was the Plague at Athens. During the Middle Ages it destroyed one and a quarter millions of people in Germany alone. Seventy thousand died from it in London in 1664. It was the Black Death. It is to be seriously questioned whether the word plague as it occurs in the Old Testament means always the same disease; indeed, probably not. In the Old Testament the term plague seems to have been applied to any epidemic disease, usually occurring in cities or camps, rapidly fatal to a great number. Let us analyze the five epidemics among the Israelites. (1) the plague caused by eating the quail. (Nu. 11, 31-33). This sounds much like ptomaine, or meat poisoning, though it may have been the pulmonary form of the plague. (2) the disease among the spies sent by Moses to explore

the region of the Red Sea (Nu. 14, 37). It is idle to speculate what this disease was, possibly cholera. (3) the plague that destroyed 14,000 after the rebellion of Korah (Nu. 16). This resembles the real Black Death more than any of the other epidemics, especially since it followed an earthquake. (4) The plague of Baal-Peor from which 24,000 died (Nu. 25). This was in all probability a venereal disease, most likely syphilis. Baal-Peor was a phallic god, and worship of this god seems to have been the ascribed cause of the disease. (5) a three days' pestilence that destroyed 70,000 (II Sa. 24, 13-15). This may have been the plague, cholera, or influenza. It is manifestly impossible to identify each epidemic with a definite disease as known to science of today.

In passing it may be well to call attention to the fact that the ancient Hebrews were prone to exaggerate numbers. For example, 600,000 warriors are said to have left Egypt, implying a total population of a million or more—an incredible number to have participated in the Exodus. In I Ch. 21, 5, it is stated that Israel had a population of over a million, with 480,000 warriors in Judah. When Sennacherib overran the country the Israelites numbered about 200,000 all told.

There are other plagues of the Old Testament that have caused much discussion. One is the sixth plague of the Egyptians (Ex. 9, 8-11). It was probably an eruptive disease accompanied by abscesses and ulcers—boils and sores. The two most plausible guesses are anthrax, or smallpox, for the disease affected both man and beast. This was probably the so-called "botch of Egypt." The death of the first born was probably due to some epidemic disease. Another is the plague of the Philistines (I Sa. 5). This was probably syphilis, and will be more fully discussed under the venereal diseases. 185,000 of Sennacherib's army are said to have been smitten by an angel (II K. 19, 35). We do not know what this visitation was. A great deal of energy has been expended in the effort to explain the "fiery serpents" that were visited upon the Israelites, and of which frequent mention is made (Nu. 21, 6; Dt. 8, 15; Is. 14, 29; 30, 6). Actual serpents and their bites may be meant. The term may be a euphemism for venereal disease. An ingenious explanation is that these fiery serpents were guinea worms. These worms are several inches long, enter the skin, especially of the legs, produce ulcers and abscesses, and are the cause of the so-called guinea worm disease that occurs in the East.

Eye diseases and blindness were, and still are, common in the Orient, due to neglect and to the blinding glare of sun and sand. Leah was "tender-eyed" because she had ophthalmia (Gn. 29, 17). Sudden blindness—transient or permanent—was not uncommon. The loss of sight due to advancing years was well known. Isaac (Gn. 27, 1); Jacob (Gn. 48, 10); Eli (I Sa. 3, 2; 4, 15). Moses had probably the farsightedness of old age (Dt. 34, 7).

The venereal diseases, gonorrhea and syphilis, were prevalent among the ancient Hebrews. Irregular sexual relations were widespread. There are many references to prostitutes and brothels. Possibly the best known are Rahab of Jericho, Delilah the Philistine, and the two harlots—probably Greek—who came before King Solomon (Jos. 2, 1; Jdg. 16, 4-18; I K. 3, 16). Read Gn. 38; Ezk. 16 and 23; Proverbs 7 is a classic. Sexual perversions were very common (Gn. 19; Lv. 18, 21). The cities of Sodom, Gomorrah, and Gibeah were notorious for the number of sexual perverts among their inhabitants (Gn. 19, 5; Jdg. 19, 22). Much of the "uncleanness by issues" of Lv. 15 undoubtedly refers to gonorrhea. Syphilis is the only disease known that visits the sins of the father upon the children to the third and fourth generation. The word "emerods," also translated "tumors," which occurs in I Sa. 5, 6-9, and Dt. 28, 27, meant the sexual organs, and was used to specify disease of those organs. By making "golden emerods" and worshiping copies of the diseased parts (I Sa. 6) the people hoped that the disease itself would disappear, the idea that like cures like being a very old superstition. This was the plague of the Philistines and was undoubtedly a venereal disease, probably syphilis. The plague of Baal-Peor, previously mentioned, was almost surely syphilis. Nu. 5, 22-27; II Ch. 21, 13-15, may refer to syphilis. It has been claimed that Sarah, Abraham's wife, and David both had venereal disease. The passages quoted in support of this contention are not conclusive. Certain verses of Psalms have been said to refer to gummata of the bones, the subcutaneous tissues, and even the liver. It is fairly certain that the Hebrews recognized the relationship of sexual intercourse and certain diseases, as attested by several passages, especially in Proverbs (Pr. 2, 18; 5, 11-22; 7, 23).

There are a few special invidual cases that are of interest. Asa died of a disease of his feet (I K. 15, 23; II Ch. 16, 22). It was probably not gout, but either senile gangrene or dropsy, because it "moved upwards in his body." King Jehoram died of a cancer of the lower bowel, or of a severe dysentery at the comparatively young age of forty years (II Ch. 21, 18-19). King Hezekiah's disease is mentioned in three different places (II K. 20; II Ch. 32; Is. 38). It is described as an inflammation, or boil, and was cured by a fig plaster, or, literally, "by rubbing a cake of figs upon the boil." A very ingenious and not at all improbable theory is that this so-called boil was a neck abscess that later ruptured; for Is. 38, 14, reads "like a crane or a swallow so did I chatter"—the idea being that the abscess interfered with the action of the larynx and so with speech. We do not know what were the diseases of Abijah, Banhadad, Elisha and Joash (I K. 14; II K. 8, 7-15; 13, 14; 2 Ch. 24, 25).

There has been a great deal of discussion about Job's disease or diseases. The ancients believed that he had "black leprosy." The usual guesses—for that is all that they can be—are leprosy, syphilis, and Aleppom boil. It has been said that to fulfil all the symptoms presented, Job must have suffered from leprosy, elephantiasis, nightmare, gout, dysentery, ulcerated mouth, marasmus, and lice! (Job 2, 7-8; 4, 13-15; 7, 3-5 and 13-14; 16, 8; 19, 17 and 20; 30, 17-18 and 27 and 30). It is probably better, at least for our purposes, to regard Job as an allegorical, rather than as an historical character.

Diseases and abnormal conditions of the nervous system were present among the Hebrews. The state of trance was recognized (Gn. 2, 21; 15, 12). Fainting attacks are told as occurring to Eli, Daniel, and Saul. Epilepsy was observed (Nu. 24, 4). Sun or heat stroke was not infrequent (Is. 49, 10). We read that "the sun shall not smite thee by day, nor the moon by night" (Ps. 121, 6). To be moon-struck meant either epilepsy or lunacy. Jonah was stricken by the sun and heat (Jon. 4, 8). The in-

cident told of the widow's three-year old son in II K. 4, 18 refers in all probability to such a sun or heat stroke. The boy went into the harvest field to his father, he suddenly cried out, "My head, my head," and was taken home unconscious. Elisha was summoned and revived him. Another widow's son was revived by Elijah (I K. 17). This child's unconsciousness was probably due to infantile convulsions. Apoplexy and its results were recognized. Uzzah's death by the ark was probably caused by a stroke, possibly by an electric shock (II Sa. 6, 6-7). Nabal died of a stroke of apoplexy due to arteriosclerosis, following a drunken feast, a common occurrence as all physicians know (I Sa. 25, 36-38). The palsy of King Jeroboam was caused, probably, by the temporary arrest of an embolus or blood-clot, in a vessel of the brain, or of the arm itself (I K. 13, 4-6).

Of course, the ancient Hebrews had no classification of mental diseases. The belief in demons was widespread. Normal reason, normal mentality, and normal mental processes were to their minds, literally, the indwelling of the spirit of God. When a person's reason weakened or was lost, an evil spirit had entered into the individual. The person thus became insane. Insanity was not infrequent. David feigned madness, crudely but successfully, and so escaped from Achish, King of Gath (I Sa. 21, 13-15). Lunatics are carefully respected in the Orient. The two most noteworthy cases of mental disease recorded in the Old Testament are those of King Saul and King Nebuchadnezzar.

The case of King Saul is very interesting. The King of Israel was handsome, shy, self-conscious, of weak judgment and violent passions, easily exalted or depressed. He had troubles at home and abroad. His enemies pressed him hard. He was threatened with loss of his kingdom. He became a prey of fears, had premonitions of his own death and showed homicidal tendencies. Samuel was dead and the priests had been driven away. He had no one to advise or counsel. In disguise and at night, harrassed by haunting fears and loneliness, he consulted the witch of Endor. Little wonder that she could conjure up for his distorted mind, Samuel's spirit. Weak from lack of food and weak with fear he fainted. He had hallucinations of sight and hearing. Some time later, sorely wounded, his sons slain, his kingdom lost to the Philistines in battle at Armageddon, King Saul fell upon his sword and committed suicide. The development and course of King Saul's mental malady may be traced in I Sa. 16; 19; 22; 28; 31. It was either melancholia, or, more likely, manic-depressive insanity.

The other interesting mental case is that of King Nebuchadnezzar as related in the book of Daniel. This king of Babylon had visions of grandeur. A dream and its interpretation preyed upon his mind. He had hallucinations, ideas of persecution, and periods of exaltation followed by depression. At the end of a year he was driven away from men. He believed himself an ox, and for seven years lived as a beast, neglecting all care of his body, and eating grass. His was probably the mental disease called paranoia, though at the end of seven years he is said to have recovered his reason. The whole story has a legendary sound. Compare the story of the companions of Ulysses becoming swine, and other old Greek tales of lycantropy.

The mysteries of sex, pregnancy, and birth have always attracted and held the interest of all peoples of all times. The ancient Hebrews were no exception. No other medical subjects are so thoroughly covered in the Old Testament. The Hebrews discussed the primitive facts of life brutally, openly and unashamed. Without question, much that is really valuable has been lost to the most of us by the translators toning down or eliminating passages that might shock our sensitive modern ear.

We cannot enter into any of the interesting detail of the obstetrics and gynecology of the Old Testament. We can glance at but a few passages.

A very old belief of ancient cattle breeders in the influence of prenatal or maternal impressions on the offspring is recorded in the last part of Gn. 30. The close relationship of menstruation, nursing, and the menopause to childbearing was well known (Gn. 18; Hos. 1, 8). It was observed that miscarriage might follow bodily injury or mental shock (Ex. 21, 22; I Sa. 4, 19). Miscarriage is invoked in Hos. 9, 14. Barrenness was looked upon as an affliction, as a calamity, often as a punishment (Gn. 18, 9-15; 30, 2). Pregnancy and children, especially after years of sterility, were regarded as a blessing, as a gift from God (I Sa. 2, 5; Ps. 113, 9). Sarah is said to have given birth to Isaac at the age of over ninety years. Rebecca was barren for nineteen years. Manoah, Samson's mother, and Hannah were also elderly primaparæ (Gn. 18; 20; 21; 29; 30; I Sa. 1, 20; Judg. 13, 24). The nursing period often lasted two or three years. There are references to nurses and sick children.

Of the many births recorded in the Old Testament four are of special interest: (1) The death of Rachel in childbirth due to, or at least contributed to, by her age and the journey (Gn. 35); (2) the premature labor of the wife of Phineas, induced by the shock of distressing news, and her speedy death, probably from hemorrhage (I Sa. 4, 19); (3) the twins of Tamar, and the lacerated perineum (Gn. 38); (4) the twins of Rebecca (Gn. 25).

The two pairs of twins are interesting because the diagnosis of twins seems to have been made before birth, and also because both were hand presentations. One of twins is commonly larger and stronger than the other. This seems to have been the case with Esau and Jacob; besides, the former had an overgrowth of hair—hypertrichosis. The rules for the lying-in period are given in Lv. 12. The days for the "purifying" for a female child were longer than for a male child. This is traced to a very old superstition that it is more dangerous for a mother to give birth to a female child.

The Hebrews regarded old age as a reward for piety, as a token of God's favor. A hoary head was a crown of glory (Pr. 16, 31). David is pictured as old and stricken in years in I K. 1. One of the best descriptions of old age and death that has ever been written is found in Eccl. 12. The Preacher speaks in highly symbolic terms. It is the picture of an old man. The following seems to be the most reasonable explanation of the passage:

Verse 2. His mind, his physical well-being, often his prosperity fails. He is fretful and peevish, his pains recur, he often weeps and is depressed.

Verse 3. His arms and hands become weak; they shake and tremble. His legs are bent beneath their load. His teeth are few or gone; chewing is difficult. His sight fails, often from cataract.

Verse 4. His lips and cheeks are sunken, referring to the peculiar appearance of a toothless, aged

person's face, especially when chewing, the doors being the lips, and the street the mouth. The sound of the grinding is low because the mouth is shut and the teeth are few or gone. His early morning insomnia—very characteristic. The bird, or cock, is easily aroused and is early astir. He becomes deaf and his voice is cracked and quavering, the daughters of music being voice and hearing.

Verse 5. He is feeble; he fears new undertakings. His hair is white, the blossoms of the almond tree being of that color. There have been other interpretations of this passage. He has an annoying rupture, the belly of a grasshopper resembling the sac of a large inguinal hernia. A dried and shriveled up old man is often a burden to his friends. His sexual desire fails; or the caper berry—used as an aphrodisiac—shall fail to act.

Verse 6. His back is bent, his shoulders stooped, the silver cord being the white glistening ligaments that support the spinal column. The "golden bowl" is obscure. It may mean the watery eyes, or the chronic nasal discharge, so common in the old. It has been suggested that the loosing of the silver cord and the breaking of the golden bowl refer to the breakdown of his central nervous system, his spinal cord and his brain respectively. His bladder is weak, he dribbles urine. The circulation at his heart fails. It has been here suggested that the breaking of the pitcher at the fountain and the breaking of the wheel at the cistern refer to the breakdown of his circulation, venous and arterial respectively.

Then shall the dust return to the earth as it was; and the spirit shall return unto God who gave it.

THE NATURAL HISTORY OF CANCER.

By ROBERT BELL, M.D.,

LONDON, ENGLAND.

FELLOW OF THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS, SUPERINTENDENT OF CANCER RESEARCH, BATTERSEA HOSPITAL, PRESIDENT OF THE MEDICAL ASSOCIATION FOR THE REDUCTION AND PREVENTION OF CANCER, ETC.

It is a most extraordinary circumstance that when a person has become the victim of cancer he or she will willingly submit to the most rigid regimen that may be prescribed with a view of combating the disease, yet, though the fact is as clear as day that cancer is a most easily preventable disease, the public, either from folly or ignorance, persistently refuses to adopt a mode of life which, if adopted, would speedily render the malady nonexistent. I make this statement advisedly, being fully assured that cancer is neither hereditary, contagious, nor infectious, and that it cannot possibly come into existence if the blood is kept in a healthy condition, which is quite possible when dietetic and hygienic precautions are carefully observed.

When we come to realize that, as matters now stand, 25,000,000 of the population of the globe are destined to die of cancer, all of which high mortality from this disease might be avoided, it surely, therefore, is time the civilized world should wake up to this vital fact. Moreover, we are aware that during the past fifty years the death rate from cancer has been going up by leaps and bounds, until the mortality from this cause to-day is greater by 200 per cent. than it was in the sixties.

Cancer is a disease consequent upon a toxic condition of the blood, which has existed with little or no intermission during a prolonged period, the consequence being normal cell metabolism has become so seriously interfered with that, in any part which has been weakened by an injury or persistent irritation, cell metabolism has been supplanted altogether and been replaced by cell metamorphosis, the cells in that region thereby being converted from enfeebled normal cells into a malignant neoplasm, completely dissociated from physiological control. Such being the case, the new growth has ceased to exist as a portion of the human microcosm, and therefore has established itself as a foreign body which has taken root upon the subjacent tissue. Now, this could not possibly have been accomplished had its environment been possessed of the normal resisting power to disease which every cell possesses when it is being nourished by a healthy blood stream. We have then established upon this devitalized tissue a morbid growth, composed of metamorphosed cells, which have separated themselves from all physiological control and which have taken on a new rôle of existence. They, in consequence of their preying upon their environment, have assumed a fungoid character, and like all fungi—to which class of organisms I have demonstrated by microphotography, cancer bears a strong resemblance—their power of cell proliferation becomes enormously increased, and, *pro rata*, their disastrous effect upon their host becomes rapidly manifest.

It has been long accepted as a plausible theory that secondary deposits of cancer are due to the migration of its cells from their original seat to distant organs and tissues, these being conveyed by means of the lymphatic vessels. This I hold to be fallacious, and for the reason that the caliber of these tubules would not permit of the passage of a cancer cell. How, then, are we to explain satisfactorily the modus operandi of metastasis?

My conviction is—and this is founded upon actual observation—that cancer in its varied forms possesses one characteristic in every instance, which is that it is a fungoid growth, and that of a malignant type. The polarity of its cells is opposed to that of the healthy cells of the body. Its method of obtaining nourishment is that of a fungus. Its rapid and increasingly rapid proliferation of cells is that of a fungus. The nature of the soil upon which it is planted, viz., devitalized organic matter, is that of a fungus, and this soil yields to a fungus the nourishment which accounts for its marvelous rapidity of growth. The fact that its secretions are acrid and highly toxic also favors this conclusion. But by far the most conclusive evidence which I adduce is the fact that it ripens like any other fungus, and produces spores as vegetable fungi do. This I was able to demonstrate during my microscopic researches about three years ago, when I was called in consultation to see a case of cancer of the ovary. In such cases we are well aware that the peritoneal fluid frequently contains a considerable amount of flocculent material. On this occasion I took some of this home with me for examination and found that these flocculi were composed of a colony of capsules measuring about 1/200 of an inch in diameter, and that they were filled with what appeared to me to be granular matter.

I managed to get one of these isolated under a cover glass. This I wrapped up in wet lint, and, twenty-four hours afterward, examined the slide again, when I found this capsule had ruptured and the field under the microscope was covered with the spores it had contained. Of this I took a microphotograph.

With this experience I think I am entitled to conclude that the flocculent particles suspended in the ascitic fluid, and which are actually fungus growths, were developed from spores thrown off from the diseased ovary. This being the case it only stands to reason that a similar state of affairs exists in other organs and that these spores are so very minute in size that they are discernible as separate entities only under a microscope giving a magnification of 1,000 diameters, and therefore can readily pass through tubules of the smallest caliber.

Knowing then that when metastasis occurs the secondary growth does not partake of the character of the structure of the organ to which it has been transplanted, but retains all the histological features of the primary growth, it is only natural to infer that this is the product of spores which have been conveyed to, and located themselves upon, the organ or tissue secondarily attacked.

Moreover, we have only to look upon the fungating outgrowths which occur in advanced cases of cancer—the cauliflower excrescences in cancer of the uterus, for example—to prove that my theory of its nature is correct.

Now, it is a well-known fact that a fungus is able to take root and develop only on decaying, dead, or devitalized material. Does it not appeal to one, then, that, if the soil upon which it has hitherto derived its nourishment is revitalized by judicious treatment, the lower form of life will be starved out of existence, and gradually succumb to the improvement in its environment? And this, beyond doubt, is the means which prove effectual when cancer is subdued and overcome by dietetic, hygienic, and therapeutic measures. How much more effectual, then, in eradicating this terrible scourge are those preventive measures—a reformed diet, attention to hygienic laws, especially those bearing upon a sanitary condition of the colon—which make it impossible for that soil to exist within the body, without which the cancer neoplasm could never obtain a footing.

That this view of the pathology of cancer is correct is further strengthened by the well-known fact that cancer cells, equally with fungus cells, contain a much larger percentage of lecithin than normal tissue cells do. Indeed, it is chiefly from fungi that commercial lecithin is obtained. It is widely distributed throughout the animal body, being found in the blood, bile, serous fluids, brain, semen, pus and white corpuscles, but only in limited quantities, whereas in the cancer cell and in fungi it is in very great excess and seems to exert a powerful influence in promoting cell prolification of a morbid type, which is a characteristic feature of cancer. Now, lecithin, being a substance of a highly complex nitrogenous composition, must necessarily depend for its abnormal increment upon a soil containing an undue amount of decomposed nitrogenous products, such as those derived from the fermentation of dead animal tissues, which are so largely consumed in food. I say dead animal tissues, but this applies also, though to a less extent, to vegetable protein substances, which have had their vital constituents, and also their organic salts, destroyed and, to a large extent, washed away in the process of cooking.

Neither the animal fungus, which is named cancer, nor the vegetable fungus can possibly exist in a soil free from decomposing organic matter, and as the blood is the source of nutrition in the animal frame, and therefore the soil upon which every cell is dependent for its existence and continuance as such, the cell can remain healthy only so long as it is provided with suitable nourishment. And I maintain that it is possible to retain the blood in a healthy condition only so long as it is supplied by the products derived from materials which have not been deprived by heat or other means of their vital principle. Such is Nature's law, and it is no use kicking against this, and, I may add, that man is the only animal on the face of the earth who contravenes this law by destroying his food value by cooking, and moreover is the only animal, except those who have come under the domination of man, who suffers from disease in its varied forms, and especially cancer.

I do not wish to insist that one should confine one's self, *in toto* to one particular form of diet, but I do maintain that a very large proportion of this should consist of food exactly in the condition which Nature has provided it.

It must always be observed that when there is a departure from Nature's precepts relative to diet, constipation is an inevitable result, and as this favors an undue retention of obnoxious and toxic decomposing material within the colon, thus permitting its absorption by the blood, it is not difficult to understand why constipation becomes such an important factor as a predisposing cause of disease. Of course that, to a certain extent, may be obviated by taking purgative medicine, but on this point permit me to beg of my readers to veto, as they would poison, those remedies which are so extensively advertised and which only tend to aggravate the mischief by weakening the normal peristaltic action of the bowel.

15 Half Moon Street.

A LOGICAL CLASSIFICATION OF MEDICAL LITERATURE.

By ANNA L. VON DER OSTEN,

NEW YORK.

THE wide distribution of scientific articles in reprinted form, published in America and abroad, makes it generally possible within a few years to accumulate the nucleus of a medical library, which eventually may be of material aid for research and teaching. To find a means of accommodating these pamphlets, together with noteworthy articles culled from the current journals, is not difficult when the collection is small; and a limited file of this kind causes no great burden on the memory. The simplest plan of cataloguing—an alphabetical arrangement according to authors—will suffice. But as time elapses and the library grows, it happens that the names of authors are not readily remembered in connection with a variety of subjects. The need for some effective system of classifying the literature, in order to facilitate ready access, then becomes imperative.

In an attempt at arrangement, the plan that most readily suggests itself is a subject index based on titles, with the literature filed alphabetically under authors and the index cards catalogued in alphabetical order according to subjects. The basis for classification is the important subject, or it may be more than one, of the article. The index cards are then filed under the various topics that have been assigned. Dictionary card catalogues of this character, with the subjects not grouped in a logical series but filed alphabetically, are found in all large

medical libraries where they admirably meet the needs of the general public.

But the physician who has a particular interest in certain subjects, will find it convenient to arrange his own accumulation of medical literature in some logical manner, in order that all references pertaining to a particular field may be found grouped instead of scattered from A to Z throughout the alphabetical file. If, for instance, his interest centers on the heart, he desires to find all references under that main heading, rather than under the various, alphabetically widely scattered groups of aortitis, heart block, fibrillation, endocarditis, myocarditis, etc. Various attempts at logical groupings have been made, such as the Bellevue system which is widely used for the filing of histories in hospitals; the order employed by the *Index Medicus*, and the classification of the Library of Congress. But these large systems all fall short of the strictly logical criterion; they seem simply to have "grown up" with additions made at the end instead of incorporated into the system. The logical subject file must be flexible in character, designed to fit the needs of circumstances. The object should be to make it so clear and comprehensive that others besides the librarian may profit through its arrangement. It, of course, presupposes some knowledge of medicine. It may be of general service in a medical school where numerous instructors and students have access to the accumulated literature.

A logical classification of medical literature must rest upon the basis of medicine, which is anatomy. An admirable guide for this purpose is the Latin *Conspectus* on anatomy of the *Instituti Bibliographici Internationalis* in Brussels, and which is in general use in Europe.* It is designed for use with a decimal classification, but it may be well to say at the outset that the complex intricacies of the decimal classification are not essential to the success of a logical system and may be omitted without loss. An absolutely anatomical system, however, reaches its perfection only with regard to the surgical literature.† For general medicine, which must include the whole range of the infections and intoxications, extensive modifications are necessary, though I believe it is still desirable to retain the anatomical basis as the skeleton about which the system is built.

I venture to give below a classification which is in use in the Department of Medicine of Johns Hopkins University.‡ It is an index of some 3000 reprints and more than 1000 references, and includes a wide range of subjects. It is cited here in the hope that its outline may be of practical use elsewhere in forming a guide for a rational system and thus conserving the energy wasted on classifications which when they have reached large proportions are found to be impracticable and must then be revised.

The system is deductive, proceeding from the general to the particular. While the general groupings "Anatomy," "Physiology," and "Pathology" will not be employed to any large extent, as most of our medical literature has reached the stage of scientific analysis rather than broad generalization, they are nevertheless indispensable. Under "Physiology" may be grouped all studies on metabolism other than the pathological, together with the literature on biological chemistry, experimental biology, etc. "Diagnosis" may serve as a heading for general articles on auscultation and percussion. Under the head of "Pathology" will fall all the diseases that the flesh is heir to, such as are definitely related to certain organs, as well as the infections, intoxications, and metabolic disturbances which are of a more generalized character.

MAIN GROUPS

General	Circulatory System
Anatomy	Respiratory System
Physiology	Brain and Nervous System
Pathology	Digestive System
Etiology	Ductless Glands and Spleen
Diagnosis	Genitourinary System
Treatment	Bones, Muscles, Tendons, Skin, Hair, Etc.
Symptoms	Parts
Diseases of Metabolism	
Neoplasms	
Infections	
Inflammations	Therapeutics
Intoxications	
Blood and Hematopoietic System	Miscellaneous

With regard to the anatomical portion of the system which begins with the section "Blood and Hematopoietic System," it is convenient not to confine this absolutely to the pathological literature, but also to include references on anatomy and physiology. An extensive physiological literature is often accumulated and this should be correlated with the pathological work on the same organ—not filed in a separate compartment, as is the case with most systems, that of the *Index Medicus*, for instance. Preceding the pathology of any part would be found its anatomy and physiology, as follows:

Heart
Anatomy
Physiology
Pathology

The plan of the classification under discussion is to bring all references relating to a particular organ together, so that at a glance a complete survey is available of the literature of that part from every standpoint.

To facilitate ready access, the mechanical aspects of the system are important, such as the use of colored guide cards to indicate the main and the minor divisions. One color, for instance salmon, might be chosen for the guides of the large general groups, blue for the divisions of anatomy, physiology, and pathology under the main groups, and buff guides for the smallest, the alphabetical groups of diseases. It is most helpful, if the library is sufficiently large to warrant it, to isolate the cards of each group in an individual drawer, *i. e.* having one compartment for "General," another for "Infections," "Intoxications," and one each for the great systems of circulation, respiration, digestion, etc. These mechanical considerations contribute much to the effectiveness of a file.

As regards the cards themselves and the manner of indexing, a form that has seemed most acceptable is shown on page 942.

It is possible in an index of this kind to include references to important works of which no reprint may be available, but of which perhaps a brief abstract has been made on the card itself. These cards may readily be filed with the others, if care is taken to differentiate them by a distinctive color, choosing, for instance, a blue card for references

*Publication No. 74e, second edition. It may be obtained in this country through Dr. Herbert H. Field, of Brooklyn, N. Y.

†An admirable and extensive classification of this kind for the literature of the brain, the ear, and the upper air tract has been evolved by Dr. William Sohier Bryant, of New York City.

‡It has been my privilege to develop this system for Dr. Theodore C. Janeway, Professor of Medicine, Johns Hopkins University.

only, while the cards for which reprints can be obtained from the file are white.

Neoplasms, carcinoma
Wells, H. Gideon
1909
The resistance of the human body to cancer.
Jour. A. M. A., 1909. lii, 1731-1740.

O

It may be serviceable to analyze some of the main divisions. Taking the first large group, under "Symptoms," general articles on fever, edema, general pains, sudden death, will find a place. In the group, "Diseases of Metabolism," we have diabetes, insipidus and mellitus; gout, emaciation, and obesity. Because of the difficulty of differentiating between malignant and non-malignant growths, as the line of demarcation in many cases is exceedingly fine, no attempt need be made to subdivide the group of "Neoplasms." It must be remembered that this group is intended to cover merely general discussions of tumor growth; where definite anatomical regions are indicated, as cancer of the stomach or rectum, the cards would be filed under those sections. This plan will be found most serviceable for the general practitioner or diagnostician. If, however, he makes a specialty of cancer study and desires the literature of the various growths correlated, this section of neoplasms can readily be expanded to cover this need. It may be desirable to file the cards under two groups—in this section, as well as under the organ affected.

One of the most difficult groups to classify logically is that of the infections, because the etiology in many cases remains obscure. In the system under discussion the following arrangement has been adopted:

INFECTIONS
Etiology doubtful or unknown
Erythema
Hydrophobia
Measles
Parotitis
Pertussis
Rheumatic fever
Scarlet fever
Smallpox
Typhus fever
Yellow fever

Bacterial
Aerogenes capsulatus infection
Anthrax
Cholera
Diphtheria
Dysentery
Gas bacillus
Glanders
Gonococcus
Influenza
Leprosy
Malaria
Malta fever
Meningitis, epidemic
Paracolon infection
Parameningococcus infection
Plague
Pneumococcus infection
Pneumonia (See Respiratory System)
Poliomyelitis
Tetanus
Tuberculosis, pulmonary and general
Bacilli
Bovine
Congresses
Immunity
Miliary
Prophylaxis
Sanatoria
Treatment
Tuberculin
Typhoid fever
Vincent's angina

Fungoid
Actinomycosis
Leptothricosis
Streptothricosis

Metazoon
Distoma
Filariasis
Hookworm
Mosquito
Parasites
Tapeworm
Trichinosis
Trichocephaliasis

Protozoon
Amebiasis
Black water fever
Filaria loa
Oriental sore
Relapsing fever (spirillosis)
Sleeping sickness (trypanosomiasis)
Spirochaeta
Surra
Syphilis
Etiology
Diagnosis
Noguchi reaction
Wassermann reaction
Treatment
Salvarsan
Syphilis, tertiary

Pyogenic
Pyemia
Septicemia

This grouping has been given not as a conclusively established or complete list, but merely as an indication for a possible arrangement. In the main the system employed in Kelly's "Practice of Medicine"* has been followed. As science reveals the etiology of many of these affections the first group will diminish in volume. Tuberculosis as an infection of the lungs has been grouped with the infective diseases, but tuberculosis of the bones or the spleen, for instance, belongs more logically with those parts and has been so classified. Another division which might be useful under this head would be that of filterable viruses.

The various intoxications have been arranged in an alphabetical series. Articles on the toxic effects of alcohol and tobacco belong in this category, as well as the metallic poisons, cobra bite, etc. It has been suggested that a more logical grouping would be: (1) chemical intoxications, (2) toxins.

The category of "Blood and hematopoietic system" includes only diseases of the blood itself, strictly speaking, not affections related to the mechanics of the circulation. The various anemias, leucocytosis, polycythemia, are filed here, and under "Physiology" all articles bearing on blood analysis. Blood pressure studies, however, belong rather in the group of circulatory affections, as also hemorrhage and hemoptysis. Blood transfusion likewise belongs under the circulatory system.

The main divisions of the circulatory system are:

CIRCULATORY SYSTEM
Pericardium
Heart
Arteries
Veins
Capillaries

As needed, such subdivisions as endocardium, myocardium, aorta, pulmonary, and coronary arteries may be added under the proper section. These subdivisions are found in detail in the Brussels classification referred to.

The divisions of the respiratory system are:

RESPIRATORY APPARATUS
Upper air tract
Nose
Larynx
Trachea and bronchi
Lungs
Pleura
Diaphragm

The accessory sinuses would form subheadings under "Nose," the trachea and bronchi should each have a subdivision under the joint group. Pneumonia, though one of the infections, is so definitely related to the lungs that it has been classified here, rather than with the infections. Literature on insufflation and artificial respiration would appear under the therapeutics of the respiratory system, a section following that of pathology. The diaphragm which separates the respiratory from the digestive tracts has been arbitrarily grouped with the former.

The auditory apparatus and the eye have been considered parts of the general nervous system. The main divisions, together with the literature under the first two groups, are given below:

BRAIN AND NERVOUS SYSTEM
Cerebrum
Cerebellum
Spinal cord
Nerves
Sympathetic nervous system
Vasomotor system
Eye
Ear

Nervous System
Anatomy
Physiology
Pathology
Atrophy
Chorea
Clonus
Convulsions
Epilepsy
Heat prostration
Hysteria
Myoclonus multiplex
Neurasthenia
Neuritis
Neuroses
Paralysis agitans
Paraplegia
Paresis
v. Recklinghausen's disease
Syphilis
Therapeutics
Surgery

*"The Practice of Medicine," A. O. J. Kelly, Lea & Febiger, 1910.

Brain
- Anatomy
- Physiology
  - Hypnosis
  - Psychology
- Pathology
  - Abscess
  - Anemia
  - Aphasia
  - Apoplexy
  - Cysticercus
  - Degeneration
  - Dementia paralytica
  - Dementia præcox
  - Encephalitis
  - Headache
  - Hemicrania (migraine)
  - Hemiplegia
  - Hemorrhage
  - Hernia
  - Hydrocephalus
  - Idiocy
  - Insanity
  - Insomnia
  - Mania
  - Meningitis
  - Paranoia
  - Psychosis
  - Tumors
- Therapeutics
  - Psychoanalysis
  - Psychotherapy
  - Surgery

As the library grows, the subdivisions of gyri of the brain, frontal lobe, corpus callosum, optic thalamus, pia mater, lumbar spine may be added; under "Nerves," the trigeminus, facial, vagus; under "Eye," conjunctiva, choroid, retina; under "Ear," the external, middle, and internal ears, the vestibule, labyrinth, Eustachian tube, and the mastoid process which belongs logically with the auditory apparatus.

The digestive system with its subdivisions comprises:

DIGESTIVE SYSTEM

- Anatomy
- Physiology
  - Digestion
  - Eating
- Pathology
- Mouth
  - Tongue
  - Teeth
  - Palate and uvula
  - Glands
  - Lips
- Pharynx and esophagus
  - Pharynx
  - Tonsils
  - Esophagus
- Epigastrium
- Stomach
  - Pylorus
- Umbilicus
- Abdomen
- Intestines
  - Duodenum
  - Jejunum
  - Ileum
  - Large intestine
  - Cecum
  - Appendix
  - Colon
- Rectum and anus
  - Feces
- Liver
  - Bile duct
  - Bile
- Pancreas
- Peritoneum
- Omentum
  - Mesenterium

The bulk of the literature will fall under the heading "Stomach." Articles on fasting would be filed under the physiology or the therapeutics of the digestive system, as the case might be. It is necessary to include the general group "Abdomen" for the classification of literature on hernia, enteroptosis, and relaxed abdomen. Articles on the feces also belong with the digestive tract.

DUCTLESS GLANDS AND SPLEEN
- Spleen
- Hypophysis
- Thymus
- Thyroid
- Parathyroid
- Pineal gland
- Suprarenals
- Lymph glands

GENITOURINARY SYSTEM
- Kidney
- Urethra
- Male genital organs
- Female genital organs
- Uterus
- Breast

The subdivision, "Kidney," must, of course, include the extensive physiological and pathological literature on uranalysis as well as such conditions as polyuria, etc.

BONES, MUSCLES, ETC.
- Bones
- Articulations
- Muscles
- Tendons
- Skin
- Hair

PARTS
- Head
- Face
- Neck
- Thorax
- Pelvis
- Extremities
  - Arms
  - Legs

THERAPEUTICS
- General
- Animal extracts
- Vaccine therapy
- Drugs
- Infusions
- Physical therapeutics
- Hydrotherapy
- Electrotherapy
- Radium
- Thorium X
- Gymnastics
- Massage
- Surgery

"Animal extracts" will comprise literature on adrenalin, thyroid, and thymus extracts, etc. "Physical therapeutics" covers articles on air, climate, cold, heat. The *x*-ray literature finds a place under "Electrotherapy." Psychotherapy, on the other hand, is more logically classed with the brain than with general therapeutics. In a system of this kind a group of "Surgery" may be useful, to cover discussions of surgical technique irrespective of definite anatomical parts. Articles on the surgery of the brain, stomach, etc., would, of course, be grouped with those organs.

Notwithstanding the comparatively comprehensive plan here outlined, it is not possible to avoid the "Miscellaneous" group, which must cover general biographical accounts, articles on medical education, general hygienic considerations, such as water and milk supply, sewerage systems, social hygiene, sanatoria, the management of hospitals, clinics, and the like.

In conclusion I may add that a system of this kind is admirably adapted to serve as an index of case histories filed alphabetically, using index cards to indicate the primary and secondary diagnoses. If different colored cards are used, for instance white for the primary and yellow for the secondary diagnoses, it is possible at a moment's notice to select all the cases of a certain affection that have been observed for say a decade. The value of a mechanical aid of this sort for making clinical data readily available for teaching and research cannot be overestimated.

THE DIABETIC TYPE OF PYORRHEA ALVEOLARIS.

THE NECESSITY FOR ITS EARLY RECOGNITION BY THE MEDICAL PROFESSION.

BY DAVID BERNHARDT FREUNDLICH, D.D.S.,
NEW YORK.

AFTER a period covering several years during which time I have made a close study, clinically and pathologically, of a large number of cases of all varieties of pyorrhea, I am convinced that the diabetic type is the least amenable to treatment.

The etiology, pathology, bacteriology, and prognosis of diabetic pyorrhea has been more or less studied and commented upon by the medical and dental professions but at no time have the teeth and gums been given the serious consideration that they should have in this condition.

The clinical picture presented by this form of pyorrhea is so definite that in 90 per cent. of patients suffering from diabetes the general condition might be tentatively diagnosed by it. This is particularly so in middle-aged patients. I have, in many instances, advised patients coming to me for pyorrhea treatment to consult their physician in reference to a possible systemic disturbance and had my diagnosis confirmed by a subsequent uranalysis report.

It is not the purpose of this paper, however, to convey the idea that diabetes can be diagnosed by the clinical picture of the gums alone. A positive diagnosis should be made only from the history and urinary findings.

The patient complains of sore gums and teeth during an acute exacerbation and the gums present a beefy-red appearance. The exacerbations as they come on affect groups of teeth not previously affected. The teeth are extremely sensitive at the beginning of an attack, but when brought together are not painful. Later there is a sensation of elongation; the teeth become loose, and the pain becomes often so severe as to render mastication practically impossible. On gentle pressure, a thin white or cream exudate oozes at the gum margins and if the gums are massaged, profuse hemorrhage, difficult to control, follows. The bleeding does not relieve the pain in this variety as it does in most of the other types.

A thin bladed instrument may be passed deeply down between the root and the gum. The tissues around the teeth have very little resistance and any irritation, whether it be traumatic, chemical, or bacteriological in origin may cause the destruction of the gum and alveolar process. The depth of the pocket becomes less after the exacerbation. In patients having a number of attacks, particularly if they are severe, the pockets become deeper with each exacerbation. In practically all cases there is a loss of tissue followed by the extraction of the affected teeth.

Following are two cases selected from my private practice:

Woman, 45 years old. Came to me for pyorrhea treatment. Examination showed gums to be beefy red in color. Scrapings were made from the pocket, prepared and stained. A microscopical examination made immediately disclosed the entamoeba buccalis in fairly good numbers.

The regular pyorrhea treatment was instituted, supplemented by local injections of emetine hydrochloride. After the sixth treatment of emetin, scrapings from the pockets were again examined and no entamoeba were found, with an appreciable decrease in the inflammatory symptoms.

Whether this response to treatment was due to the emetine I am unprepared to say, as other cases in my experience have responded equally as well to other forms of treatment.

The patient was instructed at the beginning to consult her physician and did so. A uranalysis showed 3.5 per cent. sugar.

Woman, 35 years old. Complained of neuralgic pain and nervousness. The exacerbation extended over a week's time. The attacks recurred every three or four weeks, each time attended by excruciating pain. At the end of a week the pain subsided, but the pyorrhea was continuous. Every form of treatment was instituted without avail. This case is cited as typical of many which come under my attention, and whose etiology should be closely studied by the medical profession, since dental treatment has been proven of little or no value.

I have frequently been asked, "What *can* be done in these cases?"

With my cases I have adopted the following method of procedure with slight modifications to suit the individual case: (1) Cooperation of the physician; (2) Expert pyorrhea treatment; (3) Education of the patient in oral prophylaxis; (4) Local injections into the gums (pyorrhea pockets) of a one-half of a 1 per cent. solution of emetine hydrochloride every day or every other day according to the severity of the case. In the majority of cases the inflammation and pain subsides before the seventh injection has been given.

Pyorrhea alveolaris of any type is bound to recur if the patient does not at all times maintain a hygienic condition of the mouth and consult his dentist at stated intervals. With the diabetic form, it is equally necessary that he should consult his physician at stated intervals in order to avoid errors in diet, etc.

The duty of the dentist and the physician to the diabetic patient is about equally divided. It is the physician's duty to have an oversight of his diabetic patient's mouth and teeth and to warn him of possible complications. If pyorrhea symptoms present, it is his duty to advise dental treatment. In this way, taken at the onset, the condition will respond to treatment and many teeth be saved that might otherwise be sacrificed.

It is the dentist's duty upon recognizing this form of pyorrhea to make careful inquiries into the patient's history and ascertain if he has been advised by his physician of any systemic disturbance and if he has not seen his physician very recently to insist upon his doing so at once, explaining to him the fact that without medical treatment the dental treatment will be of little avail.

212 West One Hundred and Twelfth Street.

Medicolegal Notes.

Divorce—Physician's Fees for Services to Children.—A divorce decree provided that the defendant should pay $10 a week for the support of his two children, the custody of whom was given to the mother, and the expense of necessary medical attention to be rendered the children by a doctor who was named in the decree. This doctor died, and it was agreed that another physician should be substituted. One of the children needing the services of an eye specialist, the substituted physician recommended one, who prescribed for the child. In an action by the specialist against the father for compensation it was held that the father's liability for medical attention to the child was limited by the terms of the divorce decree, and hence he was not liable for the plaintiff's services, rendered without his consent.—Ryder v. Perkins, Massachusetts Supreme Court, 107 N. E. 387.

Medical Works—Cross-Examination of Expert Witness.—The law is well settled in Illinois and is the general rule, that scientific books may not be admitted in evidence before a jury, and that such books cannot be read from to contradict an expert witness, except where such expert assumes to base his opinion upon the work of a particular author, in which case that work may be read in evidence to contradict him. A physician, testifying that hysteria can never result from a physical injury, but is congenital, based his opinion on his own observations and experience, without relying on any textbooks or writers on the subject. It was held that a cross-examination consisting of references to medical works, so as to convey to the jury the impression that the physician was testifying against recognized authority on the subject of hysteria, was improper.—Ullrich v. Chicago City Ry Co., 265 Ill. 338.

Privileged Communications.—Under Ohio Gen. Code, §11494, providing that a physician shall not testify as to a communication made to him by his patient, a "communication" may be, not only by word of mouth, but by exhibiting any part of the body to the physician for his opinion. The qualification that a physician may testify by express consent of his patient, and if the patient voluntarily testifies the physician may be compelled to testify on the same subject, requires an express consent of the patient, or the patient's voluntarily testifying as to the matters communicated to the physician.—Ausdenmoore v. Holzback, Ohio Supreme Court, 106 N. E. 41.

Boards of Health—Ordering Examination of Cows.—The Supreme Court of Mississippi holds that Code 1906, §§2487, 2489, 2494, 2511 requiring the State Board of Health to supervise the health interests of the people and make all reasonable rules necessary to discharge its duties and powers, etc., empower the State Board of Health to require a semi-annual examination by competent veterinary surgeons of cows used in the dairy business to ascertain whether they suffer from tuberculosis or other contagious diseases.—Hawkins v. Hoye, (Miss.) 66 So. 741.

Malpractice—Necessity for Expert Evidence.—Under the rule that a surgeon treating a patient's diseased limb does not impliedly contract to restore the limb to its natural condition, but only to use a degree of diligence which is ordinarily possessed by the average of the members of the profession in similar localities, giving consideration to the state of the art at the time, it is held that a surgeon unsuccessfully treating a badly sprained ankle by the use of a remedy known and approved by the profession, and which in some instances has achieved remarkable results, is not guilty of malpractice. In an action for malpractice in treating a limb it is not sufficient for the plaintiff to show the facts surrounding the injury to the limb, the subsequent treatment, and the ultimate loss of the limb, but there must be expert testimony tending to show malpractice, or the jury may not draw inferences of the negligence. The question of malpractice in the treatment of a limb is a scientific question and can only be answered by an expert.—Miller vs. Toles, Michigan Supreme Court, 150 N. W. 118.

THE OCULO-CARDIAC REFLEX.

THIS phenomenon which was first described in 1908 by Aschner and to which considerable attention has recently been paid consists in a change in the pulse-rate, usually a slowing, and sometimes in a change in the pulse rhythm, following compression of the ocular bulb. The reflex occurs in normal individuals, its path consisting of the fifth nerve, the medulla, and the vagus or sympathetic nerve. Persons showing the usual type of this reflex, in which the vagus forms part of the arc, are designated as vagotonics; persons in whom the sympathetic is part of the reflex arc, react to ocular compression by means of a very slight slowing or an actual increase of the pulse; these individuals are known as sympathicotonics.

Two important clinical studies of the oculo-cardiac reflex have recently appeared. The first of these, by Noel Orlandi, is contributed to *Riforma Medica*, February 27 and March 6 and 13, 1915. He finds that compression of the ocular bulb causes a slowing of the pulse in normal persons to the extent of four to twelve pulsations a minute. The same effect is observed whether the two bulbs are compressed simultaneously or alternately. If compression is repeated three or four times at intervals of a few minutes the reflex disappears. It may show considerable variation in the same individual; on one day light compression of the bulb may cause a reduction of twelve or fourteen in the pulse rate, whereas on the following day similar compression may cause a reduction of only four. In no normal subject has Orlandi ever observed an inversion of the reflex. In two instances, upon the repetition of the test following the production of bradycardia he obtained a transient acceleration of the pulse. Age has an important influence upon the phenomenon. Infants react with a more pronounced bradycardia than do adults; in women the reflex is more marked than in men. On the basis of his observations Orlandi concludes that the oculo-cardiac reflex is a normal phenomenon dependent upon the integrity of the vagus path; apparently, however, the reflex arc is frequently exhausted, for in certain instances the repetition of the stimulus causes the nerve impulse to be propagated along the sympathetic, in which case tachycardia results.

The oculo-cardiac reflex is abolished in chronic aortitis. It is absent in tabes dorsalis with a constancy comparable with the presence of the Argyll-Robertson pupil. The reflex is exaggerated in the vagotonic syndrome and inverted in the sympathicotonic syndrome. It is a useful diagnostic aid in cases of bradycardia and in certain cases of changed conductivity in the atrioventricular path, by showing the integrity or impairment of the extracardiac innervation. In other words, the oculo-cardiac reflex is an index of the functional efficiency of the vagus. But before attributing any diagnostic value to this reflex one must bear in mind the wide limits of its variability under normal conditions, and the fact that the reflex is easily exhausted by repetition.

E. B. Gunson (*British Journal of Children's Diseases*, April, 1915) has studied the oculo-cardiac reflex with the aid of the polygraph in cases of diphtheria and scarlet fever occurring in children under twelve years of age. He notes that the positive vagal effect or slowing of the pulse is an indication of the normal state of the nervous mechanism of the heart, and may be obtained even in the presence of a myocardial degeneration. The reflex is positive in about 92 per cent. of children convalescent from diphtheria and scarlet fever. The negative reflex, that is, one in which there is no slowing or an actual quickening of the pulse, occurs in all cases of so-called "cardiac paralysis" that terminate fatally; in cases that recover the reflex becomes positive when the heart returns to the normal state.

The study of the positive oculo-cardiac reflex in cases of scarlet fever and diphtheria with the aid of the polygraph shows a slowing of the whole pulse, with stoppage of the heart in some cases for as long as four seconds; a production of premature contractions; a reduction of the $a - c$ interval; a production of $c + a$ beats; and, in diphtheria cases only, a complete dissociation of auricles and ventricles. Gunson concludes that the oculo-cardiac reflex is of diagnostic value in confirming the neural origin of the great majority of the post-febrile bradycardias and in differentiating them from cases of auriculoventricular heart block.

THE ABDERHALDEN TEST IN VETERINARY DIAGNOSIS.

THE importance and reliability of the Wassermann reaction demanded that all practitioners familiarize themselves to a certain extent with its theoretical foundation, and one of the effects of its introduction has been the great interest shown in all the biological reactions which have been proposed since that time. Of all these tests the one proposed by Abderhalden, which was claimed to demonstrate defensive ferments in pregnancy and the infectious diseases, has excited the greatest interest and has had the greatest vogue. This reaction has passed through the early period of enthusiastic acceptance and has fallen into the second stage in which its reliability is being assailed on all sides. The literature on the subject is tremendous in amount, but a large percentage of it is of very little value. Now, however, the popular interest is dying out and the field is being occupied by careful scientific workers who are gradually sifting the true from the false and we can hope before long to be able to record the

demonstration of the exact value of the reaction.

Pfeiler, Standfuss, and Roepke have recently published (*Centralbl. f. Bakt.*, 1915, lxxv, 525) the results of a most careful piece of work. They devoted their attention chiefly to animals, investigating the reaction in pregnancy, tuberculosis, swine pest, hog cholera, and glanders, and in pregnancy and cancer in man. Their results were not encouraging. They obtained correct results in 59 per cent. of pregnant and 45 per cent. of non-pregnant cows, in 29 per cent. of non-tuberculous, and 70 per cent. of tuberculous animals. In horses and asses the test agreed with the actual condition in 30 per cent. of the pregnant and 27 per cent. of the non-pregnant animals. One-third of the infected animals gave a correct reaction for swine pest while none of the healthy swine gave a negative reaction. In the human cases tried the results were verified in but 50 per cent. of the cases. Many of the reactions were extremely confusing in that pregnant sera would digest tuberculous tissue and so on. They conclude that ferments which will digest placental or tuberculous tissue may be demonstrated in the serum of pregnant and tuberculous animals. These ferments are not strongly specific, but the serum of a gravid animal may attack tuberculous tissue and vice versa, or entirely different organs, as the liver, may be digested. What is more, the serum of non-pregnant and non-tuberculous animals may also contain these ferments.

In a critical résumé of the literature and of their own work the writers justify their own technique, showing it to be as free from error as possible, but complain that the method, so far from being a simple one, demands more controls than any other biological procedure. They show how the most impossible claims have been made for the application of this method to diagnosis in general, one man giving figures to show that he could thus differentiate between gastric and duodenal ulcer. They question the specificity of the defensive ferments and think that there are many uncontrollable sources of error in the method. In a word they present good reasons for believing that proteolytic ferments are constantly being produced in the blood and that under certain conditions, such as pregnancy, they may be increased, while in other circumstances their action may be interfered with. The test then becomes merely a quantitative one and devoid of diagnostic value. They have apparently not investigated Bronfenbrenner's work in which he attempted to show that the reaction was an autodigestion of the serum, subject to restraint by the presence of antiferments. The article is discouraging and yet not wholly conclusive. The favorable reports should be explained in a more satisfactory manner and many obscure points cleared up.

In the meanwhile it would perhaps be well for physicians not to place too great reliance upon the results of the test even though it be performed in the most reliable laboratories. It is probable that within the next few years it will be entirely discarded or its technique will undergo a decided alteration. Further studies may serve to clear up some of the present obscurities.

THE ACTION OF BENZOL AND ITS HOMOLOGUES.

In 1897 Santesson noted among the symptoms of benzol poisoning in workers exposed to the vapors of this substance a pronounced diminution in white blood cells. Thirteen years later Selling of the Johns Hopkins Hospital reported three cases of benzol poisoning in young girls in whom a marked purpura hemorrhagica was associated with a considerable degree of leucopenia. Two of these patients died and the principal autopsy finding was an intense atrophy of all of the hematopoietic organs. On the basis of the above observations, Koranyi essayed with success the use of benzol as a therapeutic agent in severe cases of leucemia. This experience has been confirmed by a host of others although a number equally as great have reported failures.

Recently Guiberto Bianchi (*Archivio per le Scienze Mediche*, April 1, 1915) has studied the effects upon the blood of benzol and its homologues, toluol, xylol, and cumol. He finds that benzol produces in man as well as in animals a definite leucopenia as well as an almost total atrophy of the leucopoietic apparatus. On the other hand, the other hydrocarbons belonging to the same group and having a saturated side chain, namely, toluol, xylol, and cumol, produce in the rabbit a distinct leucocytosis and a hyperplasia of the leucopoietic elements, more especially of the bone marrow. As regards the effect upon the red blood cells, benzol as well as its homologues causes a moderate diminution amounting to about 20 per cent. The blood platelets behave in a different manner. Under the influence of benzol they disappear almost entirely from the circulation; whereas under the influence of toluol, xylol, and cumol they show a relative and persistent increase in number.

The outstanding feature of the above investigation is the fact that benzol and its homologues have a similar action upon the white blood cells, the leucoblastic elements, and the blood platelets; whereas they have little or no influence upon the red blood cells or erythroblasts. Indirect evidence is also furnished in opposition to the view that the blood platelets are derived genetically from the red blood cells.

Intranational and International Ethics.

Most persons, and especially those who have kept their heads, have been greatly surprised by the conduct of some scientific men in relation to the war in Europe. It has often been said, and has been generally believed, that "science has no country," but the war to a large extent has dissipated this belief. Men eminent in science have revealed their racial antipathies with as much venom and vituperation as have ordinary citizens; indeed, they have often exceeded the latter in their foolish vaporings of hate. In an address delivered before the Columbia University Biochemical Association Dr. S. J. Meltzer inveighs and no doubt rightly against socalled international morality, although he also draws attention to the fact that war unquestionably elevates the intranational morality. It is pointed out that although science lends itself willingly and enthusiastically to the art, if it may be so termed, of destruction, there is one inspiring ex-

ception to this sorrowful rule. It is the utilization of the medical sciences and the behavior of medical men in war. In order to counteract the maleficent influences which permeate and govern international morality, the author of the address suggests that a medical brotherhood be established for the purpose of upholding and accelerating the progress of international morality. Medical men might thus become the standard bearers of civilization and humanity and by their example might guide the less altruistic members of the human race into the paths of international morality. The idea is a great one, and though it may be utopian, it is worthy of initiation by this powerful nation.

The Tuberculosis Preventorium for Children.

The knowledge that tuberculosis is contracted, to a large extent, in early childhood, has considerably altered views as to its prevention.' Dr. Alfred F. Hess in a paper contributed to the *Journal of the American Medical Association*, December 19, 1914, urged the need for segregating young children born of tuberculous parents especially of tuberculous mothers and who react to tuberculin. A move in this direction has been made at the Farmingdale Tuberculosis Preventorium for Children, where more than 180 children are accommodated and recently provision has been made for the reception of infants under one year of age. The children are kept here for an average period of about four months, so that the institution provides for nearly 600 children a year. The scheme of treatment is simple: Plenty of good food, a twenty-four-hour day in the open air, an intimate acquaintanceship with the fields and woods, and practical lessons in cleanliness and hygiene. The work of the Preventorium is intimately connected with that of the many tuberculosis clinics of New York. These clinics under the direction of Dr. James Alexander Miller are the admitting stations of the institution and every six months after release from the Preventorium the children are revisited in the home, and their physical condition and surroundings noted. The principle underlying the establishment of these institutions is eminently rational and in practice, so far, the results have been satisfactory. If tuberculosis is to be stamped out children in whom are the seeds of tuberculosis should be so cared for that they may become strong and not live to be a menace to others. Preventoriums of this character should be founded in all large cities and would doubtless prove to be factors of no mean efficacy in the prevention of tuberculosis.

News of the Week.

Committee of American Physicians for the Aid of the Belgian Profession.—The treasurer, Dr. F. F. Simpson, 7048 Jenkins Arcade Building, Pittsburgh, reports the receipt of the following contributions for the week ending May 29, 1915:

Dr. J. E. Talley, Philadelphia, Pa.	$10.00
Dr. Leonard W. Ely, Palo Alto, Cal.	5.00
Receipts for the week ending May 29	$15.00
Previously reported receipts	6,993.50
Total receipts	$7,008.50
Previously reported disbursements:	
1,625 Standard boxes of food at $2.20	$3,575.00
1,274 Standard boxes of food at $2.30	2,930.00
213 Standard boxes of food at $2.28	485.64
Total disbursements	6,990.84
Balance	$17.66

Owing to the fact that it is not permissible to ship salt into Belgium, a recent change in the price of the boxes of food from $2.30 to $2.28 caused an error in the report of May 1st. The correction is made in this issue.

Forty American Physicians in Serbia.—The Serbian Government has asked for a total of forty American doctors to fight the typhus and other epidemic diseases. Those now there, under Dr. R. P. Strong, of Harvard, number sixteen.

To Study Typhus in Montenegro.—Dr. H. A. Young sailed from New York last Saturday for Montenegro to study and report on the epidemic of typhus fever which is said to be raging there as well as in the other Balkan States and Austria. He had with him a supply of antityphus vaccine to observe its prophylactic and therapeutic value. He went under the direction of the Montenegran Relief Commission which despatched at the same time a large quantity of hospital supplies. There will probably be an opportunity for another physician, or possibly more, who may wish to work in the same field. Information regarding this may be obtained from the Secretary of the Montenegran Relief Commission, 527 Fifth Avenue, New York City.

The Cancer Campaign in New England.—The Vermont State Medical Society has arranged for a series of clinics and public meetings at Rutland, Burlington, Montpelier, and St. Johnsbury on June 8 to 11 to urge the need of early recognition of and early operation for cancer. Among the speakers will be Dr. Francis Carter Wood, chief of the Crocker Institute; Dr. W. S. Bainbridge, of New York, and Dr. J. M. Wainwright, of Scranton, Pa.

Death Rate in New York.—The Health Department reports 1,492 deaths in the city during the week ending May 22, with a rate of 13.41 per thousand, as against 1,592, with a rate of 14.88, for the corresponding week in 1914.

Rabies in New Jersey.—Under a law passed at the recent session of the New Jersey Legislature, every person knowing of a case of rabies, or of a suspected case, is required to notify the local officials, under penalty of $50 for first offense and $100 for subsequent ones. The local health boards are also empowered to quarantine any suspected animals.

Dr. Edward C. Rosenow of Chicago has been appointed chief of bacteriological research, Mayo Foundation, Rochester, Minn. Dr. Rosenow will begin his new work on July 1.

Homeopathic College and Flower Hospital.—At the commencement exercises of this school, held Wednesday evening of last week sixty-eight diplomas were given. Addresses were made by Dr. Royal S. Copeland, dean of the faculty, and the Rev. J. Henry Jowett, pastor of the Fifth Avenue Presbyterian Church.

Raising the Requirements for Health Inspector.—Dr. S. S. Goldwater, Commissioner of Health, of New York City, has announced that in future all applicants for the position of medical inspector in the department, to which physicians only are eligible, must show at least one year of hospital experience as an interne in addition to the four-year medical course.

A Hundred to One Bet on Golf.—A wealthy resident of Philadelphia has wagered $100,000 to $1,000 that he can defeat a well-known surgeon of that city at a game of golf to be played in the autumn. If he is beaten he agrees to give $100,000 to endow

a chair of surgical research in the University Medical School. The money is to be paid into the treasury of the university before January 1, 1916. If he wins, the surgeon must buy ten $100 shares of the stock of the golf club.

"Twilight Sleep" Unsatisfactory.—The St. Louis City Hospital has discontinued the "twilight sleep" treatment in maternity cases. The treatment has been employed at the hospital since last February. The reason given is that the method has not proved to be entirely satisfactory.

An American Field Hospital for France.—A field hospital, an exact duplicate of those used in the United States Army, has been presented to France by three Americans whose names are not published. The field hospital, in which are twenty tents, has been set up in the Bois de Boulogne. Six of the tents are of large size, being capable, if crowded, of taking care of 200 wounded men.

Gift of a Hospital to Cold Spring.—By the will of Mrs. Julia Lorrilard Butterfield, which has just been admitted to probate, the sum of $50,000 is left to build and equip and $100,000 to endow a general hospital for the village of Cold Spring, N. Y.

Long Island State Hospital for the Insane.—Governor Whitman has signed a legislative appropriation permitting the State Hospital Commission to enter into contracts for additional quarters for patients at the Long Island State Hospital to the amount of $400,000, $200,000 of which is available at once.

The Study of Occupational Diseases.—An opportunity to do research work in the study of occupational diseases is offered in the Occupational Clinic of the Department of Health recently established at 49 Lafayette Street. It is desired to secure the assistance of competent clinical workers in this field. A list of volunteers will therefore be established, from which to draw medical assistants for work in the clinic. In the budget for 1916, request will be made for the establishment of a number of positions for clinic physicians at $300 per annum. The hours of work will be from 10 a. m. to 12 or 12:30 p. m., three days a week. Those to whom this opportunity makes an appeal, should make application in writing to the Director of the Bureau of Preventable Diseases, Department of Health, New York City, stating their clinical experience.

The Crocker Research Fund.—The trustees of Columbia University have appointed the following board of managers of the George Crocker Cancer Research Fund: Dr. T. Matlack Cheesman, Dr. Walter Mendelson, President N. M. Butler, Dean Samuel W. Lambert, Professor Warfield T. Longcope, Professor William G. MacCallum, and Professor Francis Carter Wood.

Tuberculosis and Typhoid Fever in Pennsylvania.—In the campaign against tuberculosis, which ten years ago was the chief cause of death in Pennsylvania, one hundred and fifteen tuberculosis dispensaries have been established and three State sanatoria have been constructed at Mont Alto, Cresson, and Hamburg under the supervision of Dr. Dixon, State Commissioner of Health. In ten years tuberculosis has fallen from first to second place as a cause of death in this State, and the rate is steadily declining year by year. Four thousand deaths and forty thousand illnesses from typhoid fever was the annual toll exacted from Pennsylvania's citizens ten years ago. Today this has been decreased more than 75 per cent., and although in the meantime the population of the State has increased more than a million, the number of deaths from this cause is only one-fourth the former figure. The General Assembly has appropriated $4,632,387 for public health work in the State during the next two years, $2,975,807 of this amount being for the campaign against tuberculosis.

American Association of Medical Jurisprudence. At the third annual meeting of this association held at Long Beach, L. I., on May 22, the following officers were elected: *President*, D. Percy Hickling, M.D., Washington, D. C.; *Vice-Presidents*, Oscar W. Ehrhorn, Esq., New York; Philip Coombs Knapp, M.D., Boston; *Secretary*, Charles P. Blainey, Esq., New York; *Treasurer*, John C. West, Esq., New York.; *Members of the Council*, Drs. Reynold Webb Wilcox, New York, and Donald D. MacTaggart, McGill University, Montreal.

Examination of Dentists for the U. S. Army.—The Surgeon General of the Army announces that examinations for the appointment of acting dental surgeons will be held at Fort Slocum, New York; Columbus Barracks, Ohio; Jefferson Barracks, Missouri; Fort Logan, Colorado, and Fort McDowell, California, on Monday, October 18, 1915. Application blanks and full information concerning these examinations can be procured by addressing the "Surgeon General, U. S. Army, Washington, D. C." The applicant must be a citizen of the United States, between 21 and 27 years of age, and a graduate of a dental school legally authorized to confer the degree of D.D.S. Acting dental surgeons are employed under a three years' contract, at the rate of $150 per month. They are entitled to traveling allowances in obeying their first orders, in changing stations, and in returning to their homes at termination of service. They also have a privilege of purchasing certain supplies at the army commissary. After three years service, if found qualified, they are promoted to the grade of dental surgeon with the rank of first lieutenant, and receive thereafter the pay and allowances appertaining to that rank. Applications must be in the possession of the Surgeon General at least two weeks before the date of examination. There will be 12 vacancies to be filled.

Obituary Notes.—Dr. SIGISMUND COHN of New York, a graduate of the University of Berlin, Germany, in 1888, and a member of the American Medical Association, the American Electro-Therapeutic Association, the New York State and County Medical Societies, and the German Medical Society, died at his home on May 18, aged 54 years.

Dr. ARTHUR F. BISSELL of New York, a graduate of the College of Physicians and Surgeons, New York, in 1847, died in Baltimore, Md., after a short illness, on April 28, aged 88 years.

Dr. JAMES SPENCE of Toronto, Can., a graduate of the Toronto School of Medicine in 1884, died at his home after a short illness on April 19, aged 61 years.

Dr. ARTHUR ERNEST GALE of Chestnut Hill, Mass., a graduate of the University of Michigan, Department of Medicine and Surgery, Ann Arbor, in 1898, died at his home, following a nervous breakdown, on April 27, urged 46 years.

Dr. EMORY LINCOLN WHITE of Somersville, Mass., a graduate of the Harvard University Medical College, Boston, in 1872, and a member of the Massachusetts and Middlesex South District Medical Societies, died suddenly on April 29, aged 67 years.

Dr. Jay W. Seaver of New Haven, Conn., a graduate of the Yale University Medical School, New Haven, in 1885, a member of the Connecticut State and New Haven County Medical Societies, and for twenty years director of the Yale gymnasium, died at Berkeley, Cal., on May 6, aged 60 years.

Dr. William Fred Hutchinson of Minneapolis, Minn., a graduate of the Indiana College of Medicine, Indianapolis, in 1885, died at his home on April 24, aged 74 years.

Dr. Gardner C. Hill of Keene, N. H., a graduate of the Castleton (Vt.) Medical College in 1856, for seven years city physician of Keene, and county physician for the same length of time, a member of the Board of Education for thirty-three years, and a member of the American Medical Association and the New Hampshire and Cheshire County Medical Societies, died at his home on April 30, aged 86 years.

Dr. Franklin C. Clark of Providence, R. I., a graduate of the College of Physicians and Surgeons, New York, in 1872, died at his home, from apoplexy, on April 26, aged 67 years.

Dr. Hugh R. Rutledge of Greenville, S. C., a graduate of the Medical College of the State of South Carolina, Charleston, in 1846, and a surgeon in the United States Army during the Mexican War, died at his home on May 6, aged 93 years.

Dr. William Winslow Ogden of Toronto, Ont., a graduate of the Toronto School of Medicine in 1860, and for many years a member of the Faculty of Medicine of Toronto University, died suddenly at his home on April 22, aged 78 years.

Dr. George Jerrald Potts of Clinton, Ont., a graduate of Victoria University, Medical Department, Toronto, in 1867, formerly of Toronto, Ont., and Portland, Ore., a surgeon-major in the United States Army during the Civil War, died at his home on April 22, aged 79 years.

Dr. George F. Horn died at Darby, Pa., on April 29 at the age of 23 years. He was graduated from Jefferson Medical College in the class of 1914, and he had served as intern in Cooper Hospital, Camden, N. J.

Dr. Josiah E. Bauman of Telford, Pa., died at St. Agnes Hospital, Philadelphia, on April 30, at the age of 69 years, as the result of injuries received in being struck by a railroad train. He was graduated from Bellevue Hospital Medical College of New York City in the class of 1867.

Dr. Thomas Shriner died of heart disease at Philadelphia on May 2 at the age of 72 years. He was graduated from Jefferson Medical College in the class of 1869. He was Secretary of the Board of Directors of the Northern Dispensary.

Dr. Peter S. Donnellan died during the first week of May in London, England. He was graduated from the Royal College of Physicians and Surgeons of Ireland in the class of 1886 and from the Medico-Chirurgical College of Philadelphia in the class of 1894. He resided for a number of years in the city of Philadelphia, and he was a member of the Medical Society of the State of Pennsylvania and a Fellow of the American Medical Association.

Dr. Niles H. Shearer died at York, Pa., on May 5 at the age of 73 years. He was graduated from the University of Maryland School of Medicine in the class of 1866.

Dr. George Cornelius Bailey of Hartford, Conn., a graduate of the New York University Medical College, New York, in 1886, president of the medical staff of St. Francis' Hospital, Hartford, and a member of the Connecticut State and Hartford County Medical Societies, died at his home, from pneumonia, after a short illness, on May 10, aged 49 years.

Dr. Robert A. Stewart of Phillipsburg, N. J., a graduate of the New York University Medical College, New York, in 1878, and a former Town Councilman of Phillipsburg, died at his home on May 14, aged 64 years.

Dr. Charles N. Shellenberger of Colorado Springs, Col., a graduate of the Pulte Medical College, Cincinnati, O., in 1878, died on April 29, from heart disease, aged 59 years.

Dr. William L. McCandless of Pinckneyville, Ill., a graduate of the Rush Medical College, Chicago, in 1872, and a member of the Illinois State and Perry County Medical Society, died at St. John's Hospital, St. Louis, from pneumonia, on May 2, aged 66 years.

Dr. Seth Wight Kelley of Woburn, Mass., a graduate of the Harvard University Medical School, Boston, in 1874, the first president of the Choate Memorial Hospital, chairman of the Board of Health of Woburn, and a member of the Massachusetts and Middlesex East District Medical Societies, died at his home, suddenly, on May 5, aged 67 years.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

EPIDEMIC OF CEREBROSPINAL FEVER—DISCUSSION ON IT IN DUBLIN AND LONDON—CANCER FUND—OBITUARY.

London, May 14, 1915.

I mentioned a fortnight ago that cerebrospinal meningitis was occupying much attention; it has continued to do so, and that naturally enough considering the late outbreak in Ireland. More than one of our societies have been discussing it, and as it was most prevalent in the military district of Dublin, and the Royal Academy of Ireland meeting is held there, its discussion may claim first notice. Dr. G. E. Nesbitt began by saying 89 cases had been notified to the local government board since January, the mortality rate being 50 per cent.; so far as he had been able to secure figures. No source of infection had been traced and no two cases occurred in the same building. Early diagnosis was most important, if necessary by lumbar puncture. In military practice great search was made for carriers, but he thought in civil practice in Ireland this was not sufficiently attended to.

Dr. McWeeney suggested that cases of this disease were, in fact, instances of an epidemic catarrhal affection with a meningitis complication which occurred in a few cases. The recent discovery of the diplococcus in the blood threw light on the puzzle as to how it got from the pharynx into the cranial cavity. In a suspected case he advised examination of blood from the arm. For treatment he urged early lumbar puncture—easy enough if a proper needle was employed. The tendency of this bacillus to die off was extraordinary, and it might be due to a fulminating character of certain cases that difficulties were found in procuring the organisms.

Sir John Moore compared the statistics with those of whoopingcough which, notwithstanding its enormous mortality in infancy, was not notifiable. He was glad Dr. Nesbitt had not mentioned that misleading term "spotted fever," and asked if any

of his cases had been marked by a purpuric eruption.

Dr. A. J. Matson had attended two cases; one was so spotted that at first it looked like typhus; the other had no spots at all; both recovered.

Dr. Marshall had six cases, two of them from outside the city and so not notifiable in the Dublin district. All died except one. All hospital cases had spinal injections, but with little success except in the one case. In a prolonged case in a child he tried fibrolysin injections. Rapid improvement followed and patient was discharged, but came back in a fortnight stone deaf. In another case of a child, nearly blind, fibrolysin was tried and sight returned. No connection with any previous cases could be traced, though close investigation was made.

In London the discussion was held by the Harveian Society. It was opened by Dr. Batten, who remarked that epidemics of the disease had occurred in Europe and America during the last century; one in England in 1907-8. But it was generally with us as an endemic with seasonal variations. Flexner had inoculated the disease in monkeys and saved those so affected by intrathecal injection of an immune serum obtained from a horse. He said serum treatment greatly reduced the mortality, but there were several strains of the meningococci so a serum should be as polyvalent as possible. Sophian advocated the gravitation method of injecting, but the ordinary method was quite safe and easily regulated.

Dr. D. Nabarro gave an account of the bacteriology of the disease from the discovery of the meningococcus by Weichselbaum in 1887 down to the recent epidemic, describing the morphology and biology of the organism. Also the chemistry and cytology of the cerebrospinal fluid and its alterations in inflammation and those produced by the injection of serum. He then showed a number of lantern slides illustrating his statements.

Dr. Arkwright dealt with the disease in three periods: (1) before discovery of the organism; (2) from the isolation of the diplococcus intracellularis in 1887; (3) from the discovery of the organism in the nasopharynx of a patient and one carrier by Albrecht and Gohn in 1901. Several observers have found that though carriers are usually free from the organism in two or three weeks, in a few it remains for much longer. It has been seen from two to seven months, and Mayer relates one case in which he thought it had probably continued two years. As to prevention early detention and isolation is most important and all carriers should be separated from the outbreak of an epidemic. Overcrowding is most dangerous. Large bodies of troops should be divided into smaller units. Prophylactic vaccination is as yet uncertain.

Dr. Colebrook regarded treatment by vaccines not as alternative to intrathecal injection, but rather as complementary thereto. It was most important to exploit the vaccine very early, for choice on the second or third day. Probably nothing could help fulminating cases which ran their course within 24 hours. It might even do harm to inoculate a person so suddenly overwhelmed with the infection. An autogenous vaccine was preferable on account of the different reactions toward sera of various origins, but during an epidemic resort to a polyvalent stock vaccine might well be resorted to. Such a vaccine has been prepared of late at St. Mary's Hospital. He had had best results with doses of two to five million cocci in children and 7½ to 20 millions in adults. These small doses can be repeated every third or fourth day. He had used the stock vaccine described as a prophylactic and had hoped to get rid of the microbe from the pharynx of carriers, but this had not happened with any regularity. He had used doses up to 2000 millions, subcutaneously, and 300 millions intravenously. There was seldom any reaction except after intravenous doses.

Dr. Armstrong related some facts of an outbreak of 94 cases between January 24 and February 8. A baby of one year exposed to infection died on the second day. An infection of a roseolar type was seen on some cases of relapse, mostly on abdomen, arms, and legs; in one case general, like measles; in another resembling scarlatina. Several had herpes labialis and other erythematous patches. In one fatal case the microbe was found in both the spinal fluid and the blood. All cases of relapse with rashes had vomiting of straw-colored fluid.

Dr. John Jefferson, honorary medical officer of Rochdale Infirmary, has died at the age of 59. Qualifying at the College of Surgeons in 1879, he afterward graduated at the University of London, taking M.B. and B.S. in 1885 and proceeding to M.D. in 1887. He was at one time resident at Manila, Philippine Islands, where he was surgeon to the British Consulate. He wrote a work on "Men and Manners in Manila," another entitled "The Anglo-Saxon and the Spaniard; a Plea for Cosmopolitanism."

Walter Samuel Simpson, senior medical officer of the Worthing Hospital and Lowering College and well known for work in relation to education, has also died. He qualified in London in 1874.

SANITARY CONDITIONS IN NORTHEASTERN BORNEO.

(From Our Special Correspondent.)

DIVISION OF BORNEO—POPULATION—MEDICAL ADMINISTRATION—HOSPITALS—PREVALENT DISEASES—PROBABLE RESULTS OF IMPROVED SANITATION.

JESSELTON, BORNEO, March 15, 1915.

THERE is very little known by the outside world of conditions in Borneo, and still less about its medical and sanitary status. It may not be amiss therefore to give a brief description of what is being done by the medical profession in that isolated country to combat the diseases that afflict man.

The equator passes through Borneo, and it lies between the lower end of the Philippine Archipelago and the Malaysian peninsula, and to the north of Java. Borneo has also the distinction of being the world's largest island. It is under the jurisdiction of various forms of government. Roughly stated, the lower three-fourths belongs to Holland, and is administered as a Dutch colony more or less directly from Java. The northern fourth is more or less under British control and embraces Sarawak, which is governed by the Rajah of Sarawak, who is a Britisher. Brunei is east of Sarawak, and is governed by a Sultan who has a British advisor. Then comes a small section still more easterly, known as Labuan, which is administered as a dependency of the Straits Settlements. The northeastern part is administered by the British North Borneo Company, which is a British chartered company with sovereign powers much the same as the old Hudson Bay Company and similar organizations. It is of the

northeastern territory that this letter will deal. It may be readily reached from Singapore by a two and one-half day journey, or in a half day from the American port of Jolo. Regular steamers may be had from either of these ports at least every ten days, and, in addition, there are other steamers that make occasional calls. British North Borneo has two capitals, one Sandakan, which is used during a part of the year, and the other Jesselton, which is used during the remaining period. There are scarcely any roads or trails, and the interior is practically unsettled so far as Europeans are concerned. Expeditions into the interior have been confined almost entirely to the territory which lies immediate adjacent to and which may be reached by ascending the rivers, of which there are many.

The population of British North Borneo is estimated at 200,000 natives, 300 Europeans, and about 20,000 Chinese. As one of the primary objects of the company is to earn dividends, one would not expect to find the defenses against and the means of treating disease as adequate as in a country directly administered by a regular government. It is, therefore, interesting to note that for the calendar year 1914 the sum of 72,000 dollars (or $41,040 U. S. currency), or about 20 cents per capita; the previous year 57,858.45 dollars (or $32,979.21 U. S. currency) was spent. It is understood that the increased amount available in 1914 was the result of an investigation and report of a high ranking British medical officer.

The medical service consists of a Principal Civil Medical Officer, who has general charge of the work. Under him there are two European medical officers who are located at Sandakan and Jesselton respectively. There is an Indian physician at Kudat. In addition fees are paid to private doctors who are called upon from time to time for special service. There is a European nurse at the hospital at Jesselton, and one is proposed for Sandakan. A few apothecaries and a few hospital attendants who appear to be poorly trained, and an odd sanitary inspector or two complete the service.

A hospital of about thirty beds is maintained at Sandakan and one at Jesselton. There are smaller ones at Kudat, Tawao, and Beaufort. Sick wards are also provided at the jails. None of the hospitals has a proper operating room, but these are now in course of construction. There is also an outpatient service attached to these hospitals, at which 19,485 cases were treated during 1913. Simple remedies are distributed at a number of stations. The large rubber and tobacco estates employ physicians who look after the medical needs of the plantation employees as well as the primal sanitary necessities. All of these estates are under the general supervision of the government medical service.

The physician on duty at Sandakan is expected to look after the hospital, the insane asylum, and the leper colony. All the medical officers are required to act as health officers in the communities in which they are stationed. This includes the inspection of incoming vessels, the management of quarantine, such laboratory work as may be required by the hospitals, the analyses of food imports, meat inspection at the slaughterhouses (only beef is inspected), and such other work as falls to the lot of the municipal health officer in other countries. The hospital facilities for Europeans are very limited, and as the latter are required to pay 1 per cent. of their annual salary per day for hospital service, it practically means that the medical officer must visit them in their houses.

From the foregoing it will be apparent that the medical man in the employ of the North Borneo Company has many and varied duties to perform and of necessity has not the time to make much of a success of any of them.

Sections that have not been infected with the diseases brought in by the Chinese and other immigration seem fairly healthy. But in districts which have been so infected the death rate is high. Smallpox and other diseases and headhunting are rapidly eliminating the native dajaks, and this loss in the labor supply constantly stimulates greater immigration. The death rate for Sandakan is given at 36.02 per thousand per annum, but it is admitted that this does not include all of the deaths.

Cholera occurs frequently and usually spreads quite generally along the main routes of travel. In Sandakan 80 deaths from cholera were reported for 1913. At present the disease is again reported present along the east coast, and to be spreading. It is quite likely that it has spread to the Sulu group of the Philippines.

Malaria is the big problem and prevails throughout the country. Jesselton has an evil reputation in this respect. All types are said to occur, but the subtertian is the most frequent variety. Bacillary dysentery is infrequent but amebic dysentery is common.

There is practically no attempt made to dispose of human excrement in a safe manner. Most of the native population builds its houses over tidal flats and the nightsoil on these is washed about and furnishes food for the crabs, which are in turn used for human food. Contrary to the usual custom in Oriental countries, there is little evidence that nightsoil is used to fertilize vegetables.

Neat buildings well adapted for the purpose have just been completed at Sandakan for housing the insane. A new leper colony has been built on Berhala Island at the entrance of Sandakan Harbor. There are thirty-five lepers confined there. No attempt is made to isolate all the lepers in the territory, and at least an equal number are still at large, so that there is no opportunity to draw conclusions as to the effectiveness of isolation in reducing the incidence of the disease.

In conclusion, it may be stated that there is much reason to believe that by the application of simple sanitary measures much could be done to make the country healthier than at present. Systematic vaccination, safe disposal of human excrement, artesian wells, undermilled rice, anti-mosquito measures, hookworm treatment, and so forth would be sure to reduce the death rate within a short period.

7. Gangrenous Epiploic Appendix. Report of a Case. A. R. Kimpton.

1. Diagnosis of Early Pulmonary Tuberculosis.—J. B. Hawes, 2d, calls attention among other things to the importance of a subnormal temperature, accompanied

by a high pulse, which often constitutes an early sign in tuberculosis. Early cases of exophthalmic goiter may simulate early pulmonary tuberculosis in every way. Practically all pleurisies are tuberculous. In children one should distinguish the difference between tuberculous infection and tuberculous disease. Most individuals at some time in their life harbor a latent tuberculous focus.

2. Appendicitis.—L. Davis analyzes his experience in the treatment of 260 cases of appendicitis at the Massachusetts General Hospital. The study of this series of cases has brought out nothing new. It merely emphasizes certain points already familiar, but which perhaps cannot be too often reiterated. The great factor in the mortality of acute appendicitis is delay; delay in making the diagnosis; also to a less degree, delay after the diagnosis is made. A second factor is the practice of giving a purge during the acute attack. There is still need of preaching these doctrines to the laity and the profession. A temperature above 102.5° in acute appendicitis is distinctly rare. In the few cases in which it occurs it is of bad prognostic import. The Ochsner treatment has a distinct field of usefulness. The operation in cases involving peritonitis should be directed to removal of the primary focus if accessible, and to securing of drainage with as little disturbance as possible of the general peritoneal cavity. The use of rubber tissue or gutta-percha wicks, rectal saline, Fowler's position, the avoidance of catharsis by mouth, and the leaving of wicks undisturbed, have simplified and safeguarded the after-treatment to an enormous extent.

4. Relation of Alcohol to Accidents.—W. J. Brickley, as the resident surgeon of a Relief Station, treating 40,000 patients each year, may speak with authority upon this subject. His experience is summarized as follows: Alcohol causes accidents, obscures the diagnosis, increases the danger of infection at the time of the accident, prevents adequate treatment, increases the danger of intercurrent complications, retards the process of repair, gives a poorer end result, and increases the mortality in accidents.

5. Acidosis in Children.—A. A. Howard concludes that acidosis in children is of frequent occurrence. Recurrent or cyclic vomiting, as distinguished by the absence of predisposing factors is extremely rare. Cases apparently of this type should be subjected to careful study for possible concealed pathological conditions. The common clinical type of acidosis is what might be termed a complicating acidosis with predisposing factors. Clinically there are numerous conditions which seem capable of acting as predisposing etiological factors in the production of an acidosis. This should be considered a serious condition, the early recognition and treatment of which is of practical clinical importance. Prophylactic measures are indicated and practical. A more thorough understanding of the biological-chemical processes producing acidosis should prove of real value in the scientific treatment of the disease—which should be considered of definite clinical importance to both general practitioner and pediatrician.

6. Horse Serum Treatment of Horse Asthma.—J. L. Goodale records his experience with the parenteral administration of horse serum in the treatment of horse asthma. A case with a high initial sensitization to horse serum acquired in the course of thirty injections of progressively increasing doses of serum a determinable increase in resistance. This resistance is characterized by failure of the serum to excite hyperemia and itching when applied to the mucous membranes or to a scratch of the skin, although edema can still be produced by hypodermic injection.

1. The Medical Profession and Street Conditions.—B. Sachs states that there are two reasons why the problem of cleaning the streets is a baffling one: (1) The people are generally indifferent to the appearance of the streets and (2) the problem of street cleaning concerns many departments of the city government, which should work in co-operation. Methods should be devised by which street sweeping may be done in dustless fashion. The open garbage and the open ash can are a distinct menace to the community. Covered ash carts and covered garbage carts should be provided. It is most important that the public should be aroused from their indifference to outdoor cleanliness.

3. Vaccine Treatment of Pertussis.—P. Luttinger presents a tentative report on the curative and prophylactic value of this treatment. Pertussis stock vaccines as prepared by the Bureau of Laboratories of the Department of Health of New York City seem to have a prophylactic value when given in high doses. These vaccines seem to have shortened the duration and severity of the paroxysmal stage; the average duration of the whoop being twenty-five days, compared to forty days of those treated with drugs.

5. Forceps.—S. S. Arluck and J. Girsdansky emphasize the following points: The total percentage of forceps (5.5 per cent.), used in a series of 6,000 cases, is a very low one. They ascribe this to the fact that the patients were given a very strenuous test of labor. The high forceps has been practically eliminated as an operative procedure, thereby materially decreasing the infant mortality. Cæsarean section and pubiotomy have proved admirable substitutes, and with more experience and improved technique are continually giving better results. Pituitary extract has proved of extreme value in cases of dystocia due to dry labor—posterior or parietal positions, etc., where no disproportion exists, as is shown in the statistics of the last two years compared with those of previous years. In a series of "twilight" cases, small compared to the grand total, the use of forceps was markedly increased from 4.5 to 9 per cent. In order that one may practise obstetrics scientifically, the cases must be individualized, so that proper treatment may be instituted to meet certain definite conditions. Furthermore, due consideration must be given to patients suffering from relative disproportion between fetal head and pelvis, and a proper test of labor permitted before interference is decided upon in order to conserve the best interests of both mother and child.

6. Rectal Polyp in Childhood.—H. Neuhof states that the question of the relation of rectal polpy to rectal prolapse in children has received very scant attention; widely divergent opinions are held by different observers. Rectal polypi were found in ten of thirty-three cases of prolapse; this does not include the transient prolapse of infancy. The removal of the polypi resulted in permanent cure of the prolapses. Visible prolapse does not result when polypi protrude from the anus. Rectal prolapse associated with blood and mucus in

the stool indicates a rectal polyp almost invariably; prolapse without blood and mucus in the stool excludes a rectal polyp almost invariably. Rectal polypi are readily overlooked; special methods of examination for their detection are described. A rectal polyp should not be removed by avulsion but invariably by ligation through the base of its pedicle.

2. Scopolamine-Morphine Treatment in Labor.—J. L. Baer concludes from his experience that the prolongation of labor, the increase in the number of fetal asphyxias, the excessive thirst and intense headaches that are so distressing, the difficult control of patients and avoidance of infection by soiling of the genitals, the more frequent postpartum hemorrhages, the blurred vision, the ghastly deliriums persisting far into the puerperium, the inability to recognize the onset of the second stage unless by risk of more frequent examinations, the masking of early symptoms such as antepartum hemorrhage, rupture of the uterus and even eclampsia, the violence and uncertainty of the whole treatment, the general bad impression given to one's patients who are being taught to approach the "horrors of labor" in fear and trembling, constitute so severe an arraignment of this treatment of labor cases that the author feels compelled to condemn it, leaving open the question of the merits of a single dose of morphine and scopolamine in those cases in which morphine and atropine have hitherto been given.

3. Scopolamine-Narcophine Seminarcosis. — W. E. Libby following the method of Siegel, who has used narcophine as a substitute for morphine and thinks it has less effect on the child, has tried this drug in thirty-five cases, giving it after the commencement of labor and the cervical dilatation had progressed for from two to four centimeters or more. Siegel's schedule, if implicitly followed, sometimes seemed to cause the cessation of uterine contractions or asphyxiation of the infant. Consequently the author has limited the use of narcophine to the initial dose unless the effects of that dose were insufficient or wore off. Except in five cases chloroform inhalations were employed toward the conclusion of the second stage of labor and he believes that aseptic measures can be better carried out when this is done. The prolongation of labor due to the use of scopolamine has been admitted and this may be three or four hours in primiparæ and one hour in multiparæ. The contractions may or may not be impaired in the first stage of labor and unless frequent examinations are made it becomes difficult to determine when the first stage ends. As a rule patients who have been quiet become restless when the second stage begins. Pituitary extract does not stimulate patients in seminarcosis to employ their abdominal muscles and it was effective only in three out of nine cases in which it was administered. Forceps were indicated in some cases in which it failed and the frequency of forceps operation was increased. The narcosis passed away in from two to four hours. The establishment of respiration in the newborn infant is frequently delayed. It is important to make the infant cry as soon as it is born and the infant should be carefully watched for at least an hour. After the first day the effect of scopolamine and narcophine may be disregarded. The difficulty occasionally encountered in resuscitating the infant is the chief objection to the use of scopolamine and an opiate during labor. As far as the effects on the mother are concerned, the author is inclined to favor its use. He has seen no bad effects in this way but he had taken care to reject cases in which complications were anticipated. Physicians must recognize that the method is not perfect. Even slight pelvic contraction should contraindicate it, and the primary inertia not infrequent in elderly primaparæ is a contraindication. For the present it would seem advisable to employ the method only when a normal confinement can be anticipated. An intimate knowledge of obstetrics is essential and hospital facilities are desirable.

4. Tuberculous Hip Disease.—P. W. Nathan states that tuberculosis of the hip is a destructive disease, which practically always leads to marked impairment of the joint structures. So far as one knows, there is no treatment which prevents or limits the destructive process and there is, therefore, no method that prevents permanent impairment of joint function. Such being the case, it must be admitted that there is no adequate treatment for hip-disease. For the present, one must be content to choose the method which will give the patient the strongest limb to stand and walk on, irrespective of joint motion or shortening. The treatment with the short plaster-of-paris spica, with all its shortcomings, is better than any other heretofore in use, provided it is scientifically carried out.

7. Infectious Endocarditis.—G. E. Ebright notes that this condition may be secondary to rheumatism, tonsillitis, pyorrhea, septic endometritis, and other disorders, but there are many instances in which no discernible disturbance has preceded the involvement of the endocardium. In the chronic infectious type of endocarditis the beginning lesions are subendothelial bacterial embolisms. The valve leaflets being relatively poor in vascularity, the bacteria may grow faster than the leucocytes are able to destroy them, and there result hemorrhage and the formation of vegetations going on to ulceration. Resolution may, however, occur before advanced vegetations are formed, and in fortunate cases, though the physical signs are marked, there may be recovery without scar formation impairing the valve function. Leucocytosis is not found as a rule before the stage of ulceration, and may not be present when large numbers of bacteria are in the blood. Simple endocarditis differs only in degree from the malignant form and may become malignant. There is much encouragement for treatment in the case of well-marked cardiac inflammation in which ulceration has not yet taken place and bacteria have not appeared in the blood stream. Several cases of this type are reported as illustrations. In none of them was there any leucocytosis

and in none more than a slight fever. The pulse was variable. As regards treatment, the author lays most stress on absolute rest. It is advisable also to regulate the diet so as to prevent distention of the stomach and colon and eliminate as much as possible a rise in blood pressure. The use of the ice bag is also mentioned. The rest should be as nearly absolute as possible, and the patient should see very few persons. When the inflammation has disappeared and myocardial irritability has sufficiently subsided, massage and passive exercise may be of use. A safe minimum of rest in bed is three months. The use of vaccines is not unattended with danger and cardiac stimulants are unnecessary as long as the proper amount of cardiac work is performed.

7. A Bolt for the Treatment of Fractures. C. Wallace.

1. Infections of the Tonsils.—F. C. Pybus states that the tonsils may act as lymphatic glands for certain regions of the nasal cavities. They act also as a protection against the constant presence of organisms in this part of the pharynx—either in the mouth, lacunæ, or tonsil substance—should they reach it through some breach in the surface. It is also probable that in the exercise of this phagocytosis they confer some immunity against the organisms inhabiting this region. The tonsils are subject to the presence of organisms during almost the whole life, both on their surface and in the lacunæ which penetrate their substance. Under normal conditions no active invasion is apparent, but under the influence of local injury or lowered resistance infection takes place with effects of very varying magnitude. The tonsil is frequently the seat of tuberculosis; its situation is such that any bacteria entering the mouth and being swallowed pass over its surface and may gain entrance to the crypts, whether dust-borne in the air or in the food. The tonsil is readily infected with either form of tubercle bacilli, investigations showing that the bovine type is most frequently present in children.

4. Tuberculin Administration and Graduated Labor.—E. Taunton concludes from his experience that the administration of tuberculin to selected phthisical workers does not shorten but, on the contrary, lengthens, the duration of treatment. The use of tuberculin does not increase the ability to do work. It appears not only to delay the improvement in working ability, but also diminishes the ultimate ability achieved by a more prolonged course of treatment. So far as the gain in weight and the rate of gain enable one to judge, the administration of tuberculin is detrimental to the nutrition of patients to whom it is given under these conditions. The after-results in fitting patients to do their work after leaving the hospital in these cases are less favorable where tuberculin has been used than in the cases where it has not.

6. Chemistry of Rice-Polishings.—H. Fraser and A. T. Stanton find that the existence of "vitamine" in the sense that Funk has employed that word is disproven. The word itself is not objected to and may be applied to the substance when it is isolated, but the premature publication of results which, on the findings of the writer himself, are subsequently shown to be erroneous creates confusion and retards progress. At the present day the problem is no nearer solution than it was four years ago, nor is progress likely to be made until improvements are effected in the methods employed by chemists in this work; those now employed are crude and imperfect.

1. Nervous Shock in War.—W. A. Turner has studied the early symptoms of nervous and mental shock, from whatever cause, during a period of three months at the base hospitals in France. He distinguishes three groups of cases. In the first there is a definite type of mental shock in which the symptoms are essentially of a psychical character. In the second group there is a spinal type characterized by a limitation of the symptoms to the extremities and usually to the lower limbs. In a third group the symptoms are referred more particularly to the special senses. In this class the remarkable cases of blindness or amblyopia, deafness and deafmutism have been included. More specialized symptoms, such as stammering or hesitation of speech, local palsies and tic-like movements, have been included in a fourth group. In the more severe class of case the patient is entirely unconscious of his surroundings. All the usual tests applied with the object of arresting attention—such as throwing a bright light on to the eyes, pinching the skin, or clapping the hands close to the ears—fail to provoke a response. The deep reflexes, however, are normal or brisk, and the plantar response is of the flexor type. The pupillary light reflex is frequently impaired or lost. Urine is passed normally; swallowing is carried out usually without difficulty. There are cases of loss of memory or transitory amnesia which are admitted to the base hospitals for further observation. Deafness of a transient character is not an uncommon symptom resulting from the explosion of big shells in close proximity to the patient, while blindness or impairment of vision from the same cause is relatively infrequent. Hesitation of speech has been observed in several cases. The outstanding symptom of spinal shock is loss of power in the legs. There is observed a form of temporary "nervous breakdown" occurring in those who have been strong and well, and is ascribed to a sudden or alarming psychical cause, such as witnessing a ghastly sight or undergoing a harassing experience. As the result of such a shock the patient becomes "nervy," unduly emotional and shaky, and most typical of all, his sleep is disturbed by bad dreams. The dreams are of experiences through which he has passed, of shells bursting, of duels between aeroplanes, or of the many harassing sights of the war in the trenches.

6. Malignant Edema.—F. McKelvey Bell records the results in the treatment of this condition, which is also called septic gangrene, in eleven cases in a Canadian Stationary Hospital at Le Touquet, France. In other wars the mortality of malignant edema has reached as high as 90 per cent., and yet the author believes if the treatment is instituted early enough, the mortality

should be nil. It is necessary to make immediate and deep incisions down to the bone, under chloroform, by means of a 6-inch blade amputation knife. These incisions were, in the cases at Le Touquet, 4 to 6 in. in length. They were afterwards kept wide open with fenestrated rubber tubes, 1 inch in diameter, passed on transversely through the muscle to a counter incision. Not less than three, and in one case six, large openings were made. The wounds were irrigated with solutions of hydrogen peroxide of the ordinary strength, followed by a mixture of the same solution with an equal quantity of carbolic acid 1 in 100. The wounds were also lightly packed with gauze. Dressings and irrigation were repeated every three hours. A high cradle was placed over the wounded part so as to admit plenty of air. After a few hours (as soon as checking of bleeding would permit) the gauze drainage was removed and only a thin layer of gauze left to cover the wound. It is thought quite possible that had these wounds been exposed for hours to direct sunlight there would have been a more rapid result. The wounds have a great tendency to close in a few hours, and this, unless prevented by the surgeon, brings about the anaërobic conditions one is trying to avoid. A pair of forceps and the moving about of the rubber tubes prevent this accident. Night and day special nurses were employed, and since the adoption of this system of treatment (in the last seven cases) there have been no deaths. Recovery took five to seven days.

7. **Urinary Amebiasis.**—H. J. Walton describes the case of a Brahmin aged 18 years who had been suffering from hematuria for six months and from anasarca of the legs, penis, and scrotum for about three weeks. The urine corresponded with that of a patient with chronic nephritis and in addition contained numerous actively-motile entamebæ. Urinary amebiasis appears to be a very rare condition; Braun refers to nine cases, and Doflein, under the heading of entamebæ urogenitalis, gives references to 4 of the same cases as those mentioned by Braun. Baelz's case occurred in a woman in Japan; entamebæ were found both in the bladder and the vagina, and Baelz was of opinion that the parasites were introduced into the vulva with the water used for washing the parts, and that they penetrated thence into the bladder and vagina. The amebæ are said to have been very motile, with a diameter of about 50 μ. Apparently it was not stated whether they contained ingested red blood corpuscles, though the urine is described as sanguineous. Baelz's paper was published in 1883, twenty years before Schaudinn pointed out the distinctive characteristics of the pathogenic and non-pathogenic entamebæ.

Berliner klinische Wochenschrift.

April 19, 1915.

Tetanus Lateralis.—Harf mentions the new symptoms of tetanus which are coming to light during the present war. Some of these are not in reality new, because old observers have noted their presence either in mankind or animals. The author is referring to more or less localized forms of the disease. Rose claimed that local tetanus is non-existent because trismus always accompanies. Brunner, however, devoted an entire monograph to local tetanus and by consulting old authorities was able to present a number of cases, and recently modern cases have been reported. It readily appears that tetanus may not only develop asymmetrically, but may also be practically unilateral. Rose had, therefore, assumed a reactionary pose, whether consciously or not. In order to give us an idea of lateral tetanus, the author presents a case history, through which it appears that a man was wounded in the left forearm and that gradually the entire extremity became rigid. Next there developed unilateral spasm of the left facial and motor branch of the left tri-facial, and later the left half of the neck and trunk, with slight implication of the left lower extremity. Involution occurs in the inverse order. Analysis appears to show that this unilateral tetanus is due to a toxic excitation of the medulla and spine. The failure to cross to the other side may be variously explained. The infection is clearly very mild in type, the small amount of toxin ascending along the peripheral nerves with no general outbreak.

Case of Oriental Boil.—Pulvermacher describes a case of so-called leishmaniosis cutanea, not because of its rarity in Berlin, for cases are not so uncommon in skin clinics, but because on account of its infectious nature it is important to prevent its dissemination. It possesses a large number of local and descriptive designations, which lead to a certain amount of confusion. Nevertheless, it is well described in textbooks. Its full geographical location is probably not yet known. The earlier names show that it has long been known in India, Asia Minor, and Egypt, and from these centers has spread over Northern and Central Africa, Central Asia, Greece, Italy, and Brazil. The methods of distribution, the insect hosts, are not yet fully understood. In a case given the patient had been an engineer in Syria, and first of all contracted syphilis. He had received salvarsan and secondaries had never appeared. He was in Bagdad before sailing for home, during 1914, and nearly all his business associates developed the Oriental boil. He had been one month in Berlin when two lesions appeared on the back of his left hand; another followed on the upper arm, which had not been exposed to insects, and was perhaps due to autoinoculation. In diagnosis it was necessary to exclude a great number of diseases. The method of contracting the disease was not cleared up. The treatment should consist of extirpation, perhaps preceded by a salvarsan cure. The affection heals spontaneously in a year, hence proper management ought to abort its course seasonably.

Ethylhydrocuprein in Pneumonia. — This resource, known in part under a proprietary name, represents one of Ehrlich's attempts at a rational cure of pneumonia. Two articles on this subject appear in the present number. In order to be efficacious, this substance must be given very early in the disease. In the army the remedy, according to Rosenow, is given immediately after the chill. He claims that ethylhydrocuprein is entirely superior to symptomatic treatment, and that when given in season its use is invariably followed by improvement. Peiper agrees that when given early, even as late as the third day, the disease is shortened and the crisis hastened. Undoubted failures occur. No cases of diminished vision have followed the treatment.

Typhoid Spondylitis of Quincke.—Galli states that not over a hundred cases of this affection have been placed on record. It is so rare that one case may be expected among 1800 typhoid patients. It is an affection peculiar to the young, although the author reports a case in a man of 59. It begins as a sequel with most violent pains in the spine, and is greatly aggravated by gentle pressure. The pain is refractory to all narcotics, even to opium in ordinary doses. The patient lies on his back as if nailed to the bed. The medical examination and still more the act of defecation are associated with severest suffering. Painful areas are located readily, usually over an apophysis and often between two ver-

tebræ. Local disturbances are present—edema in the painful localities and a sort of yielding of the spine, which may develop into a gibbosity. In 80 per cent. of all cases the trouble is localized in the lumbar spine. No good reason has as yet been advanced to explain this condition, as a whole. Only in the individual case may some causal element be suggested. Finds of bacilli in the vertebræ, etc., are too slight and infrequent to be of significance. Pus has seldom formed. The affection, as narrowed down by the author to a typhoid sequela has a favorable prognosis. It may persist for several years. The best treatment is the prompt application of a plaster of paris corset.

Treatment of Diabetes in the Field.—Rüdiger states that many soldiers at the front have diabetes. A dietetic treatment is out of the question, for at the front there is but one diet. The medical treatment must be chiefly symptomatic, and the author knows of but three remedies—opium, bromides and salicylic acid. The first named controls the polyuria, thirst, and excretion of sugar and holds back the inevitable loss of weight. Diabetics have besides a natural tolerance towards opium. The action of the latter even persists after its withdrawal. Bromides are of use only when it is desirable to suspend the opium for a brief period—about one week. Salicylic acid in some way lessens the production of sugar in certain patients by whom it is well tolerated. As not all patients bear opium well, it may be tested as a substitute. The author does not believe in the high initial doses of opium. At most he would limit the daily dose to about two grains of the drug given in three doses. One-half or less of this amount should give the desired effect. The daily dose of bromides should be from 3 to 5 grams.

Appendicitis in the Field.—Pflaumer records the occurrence of a large number of cases of this affection in a military hospital during the Christmas holidays. This cumulation was undoubtedly determined by the senseless indulgence in food articles sent from home, in addition to the regular diet. The men were warned of the risk. Numerous cases of gastric and intestinal catarrh developed and served to bring the two conditions into relationship. The question of operation in such cases becomes a delicate one. These patients are stricken on the field. Should they be operated on at once or transported to a field or reserve hospital? Should they be operated on in the acute or interval period? Only protracted experience can answer these questions. Twenty-three cases of appendicitis developed before and after Christmas. In fifteen immediate operation was advised, and in twelve the patient's consent was obtained. The patients of this series were all in a reserve hospital and some of the cases were far advanced. In five cases there was perforation with ichorous abscess and all the patients were saved and able to rejoin the ranks. In the other seven cases operated on the condition was relatively benign and all rapidly recovered.

Functional Testing of the Heart.—Katzenstein gives the results of ten years' clinical experience in this direction. Many years ago he sought to develop the principle of the intercalation of resistance somewhere in the blood circuit. Recently others have made reports upon this procedure. The principle involved is compression of both femoral arteries in order that the behavior of the left ventricle may be watched. Back of this lies the ability to form a collateral circulation to obviate the results of compression. When large arteries are ligated the blood pressure rises, while the pulse is undisturbed. This pressure rise cannot be due to increased fluid in the circulation, for it is persistent, and several arguments are advanced to prove that it is due wholly to increase in the work of the left ventricle. The author applies a Gärtner's tonometer, and obtains several pressure readings, the patient being in bed. The femoral arteries are compressed digitally for from 2 to 2½ minutes. If now the blood pressure rises and the pulse becomes slower the action of the heart is normal. If we find no rise in the pressure and no change in the pulse the heart is nearly normal, *i.e.* but slightly damaged. Finally, if the blood pressure sinks and the pulse rises we may infer that the heart is notably damaged, or markedly insufficient. The author is a surgeon and makes use of this method almost daily; in all he has made 3,000-tests of this sort. The mortality in 3,000 operations has been 3.2 per cent., with no death from narcosis. The patients with poor hearts were refused operation, save when the latter alone could save life. The author believes that he has eliminated sudden death from heart failure. The above mortality record concerns chiefly secondary mortalities evidently not attributable to cardiac insufficiency.

A Procedure for Fastening the Liver in Hepatoptosis.—Gross speaks of the great frequency of visceroptosis, especially in women. The organs concerned chiefly are the liver, stomach, and colon. The loosened liver by reason of its weight plays a greater rôle through the movements of the body than is commonly believed. In abdominal enlargement, as in pregnancy, the pull at the navel upon the ligamentum teres of the liver is perhaps a cause of the sinking of that organ. In the course of laparotomies it is not difficult to perform hepatopexy, but considerable time is added to the intervention. It is a matter of sutures and drainage. The author quite accidentally in operating for a complicated condition in the bowels recalled the fact that the hepatic ligament is used to constrict the pylorus after a gastroenterostomy. As a rule, the ligament remains very strong. If one divides it near the umbilicus and makes traction on it, the liver is strongly tilted upwards, just as in spontaneous hepatoptosis. When a suitable case came along the author drew the cut ligament upwards sharply and attached it to the ninth rib. As a result the anterior margin of the fallen liver was raised at least 10 cm. In a case reported by the author the woman also had gastroptesis of the third degree (below the navel), which required a posterior gastrostomy. As a matter of fact, the chief indications for operation came from the stomach.

Treatment of Frozen Digits.—Wittek saw a very large number of frostbites of varying degrees and recalled the experience of Noesske in saving a gangrenescent finger by withdrawing all the stagnant venous blood, and then using methods of forcing fresh arterial blood into the member. The author contented himself with making free incisions into the lifeless fingers (an anesthetic was not necessary). Afterwards he dressed with collargol. The incisions were of undoubted benefit in antagonizing the process, reducing the amount of slough, and producing a more peripheral line of demarcation, so that a lower amputation could be made. Bundschuh writes on the same subject, to wit, the application of Noesske's principle in frostbites of the third degree. He used in addition to incisions, the finger stall (Bier method) to force blood into the scarified finger as suggested by Noesske, and believes that it should be employed daily for a time for 10 to 15 minutes. The dressing was an oil tamponade.—*Münchener medizinische Wochenschrift.*

Insurance Medicine.

THE GENERAL FACTORS DETERMINING MEDICAL SELECTION.

FROM "ALLGEMEINE LEBENSVERSICHERUNGSMEDIZIN" BY PROF. DR. GEORG FLORSCHÜTZ OF GOTHA.

(*Continued from page* 916.)

We now see what we had previously been led to expect, that the measurements and weight figures of the tuberculous cases do not invariably lie below the average or below the normal, but just as is the case with controls themselves, show a marked excursion in positive and negative directions. However, and this is very important for us, the negative variations prevail in a striking fashion; so that about two-thirds of the chest measurements and about three-fourths of the waist measurements and weight figures can be counted as subnormal. It further appears that the form of the thorax does not play the rôle in the doctrine of predisposition that has been imputed to it by Freund and Rothschild. The more or less paralytic or otherwise altered thorax is of value only as part symptom of an inferior constitution. The essential moment is the general nutrition, *i.e.* the subdevelopment as expressed simultaneously in girth and weight.

The investigations may be carried to still greater completion, however, if we isolate certain classes of tuberculous cases. Thus I have investigated how the course of the deviations of the tuberculosis death cases present themselves when we exclude those who had been engaged in occupations which had to do with the manufacture and sale of alcoholic beverages. The deviations to the negative side became at once more conspicuous, while a portion of the extreme positive deviations vanished, and would vanish entirely if we could take out all the chronic alcoholics who succumb to phthisis on an alcoholic basis. Fundamentally these cases do not belong to our investigation series. They are allowed to remain because otherwise we could not have evaded the reproach that investigations had been made in a material specially selected as tuberculous.

In the case of genuine phthisis—and this it is which alone interests us here—it is all the more certain that the inferior constitution is a decisive factor in the origin of the disease, and in estimating the constitution the girth and weight are of first importance, the chest measure less so. The inferior constitution is not the only factor as it is not the absolute predisposing cause of phthisis; but it stands out distinctly above the other predisposing factors, which group themselves about it and often maintain their importance only in connection with it.

That infection is necessary in order to acquire the disease is self-evident; but how very seldom this is demonstrable in life insurance practice is apparent from the statistics which show that of 1,428 deaths from tuberculosis there were but 11 in which the husband or wife of the deceased was tuberculous. Of course, in medical selection one must certainly consider the risk of infection when it is so evident as in conjugal intercourse, but in general so far as life insurance is concerned one may regard tuberculous infection as purely a matter of chance. The real deciding factor is the morbid tendency, or disease substratum—in other words, the constitution.

In what relation, however, does the latter stand to heredity? That there is actually an heredity problem in the etiology of tuberculosis Table 5 gives us no reason for doubt. This table shows the number with tuberculous taint among those dead of tuberculosis and among the controls. A comparison of the percentages speaks so plainly that any further discussion of them would be a waste of words.

The result of a comparison of the tainted tuberculous cases with the tainted control cases is most striking and shows the importance of a careful study of the constitution in tuberculous selection. For only one answer is possible to the question, "why did the tainted subjects die, and not the others as well?" Because the others were quite differently, quite notably better constituted, because they had not, like those who died, an inherited constitutional inferiority or—as we could say, without prejudice to the selection—had not acquired the same in early life.

At the Fourth International Congress for Insurance Medicine in Berlin in 1906 I communicated the results of my various investigations. One of the chief topics for discussion was the precocious establishment of a tendency to tuberculosis and especially to pulmonary tuberculosis.

Not long before Gottstein had instituted a similar investigation with the material of the Victoria-Berlin Life Insurance Company, which was restricted, however, to the percentage relation between the chest measure and height in tuberculous and non-tuberculous subjects. He, too, had found in agreement with myself that in the tuberculous the chest measurements were relatively smaller than in the non-tuberculous, and also so remained, although for each age-group an increase appeared with increasing age. It was also established that this is independent of the duration of insurance and is present whether the interval between the date of insurance and the death is one of 1, 5, 10, or 20 years. It is, therefore, proved that the small chest measure of the eventually tuberculous subject is a primary manifestation and not the consequence of a pre-existing disease.

Lately, the medical director of the Lübeck Life Insurance Company, Dr. Mollwo, undertook a verification of my work upon the material of his own company and found that my results were correct. It would be superfluous then to reproduce his figures. I quote only the leading propositions which he derives from them for medical selection.

"There is a disposition to tuberculosis which may be expressed in figures. The inferior build is not the result of, but a predisposition to the disease. General inferiority of the measurements of the examined gives the first and best hint for the selection. Heredity is then present when it shows itself in a defective development of the body, in an inferiority determined by measurements. Finally infection is a matter of chance. The development of turberculosis is not so much dependent on chance, however, but can be predicted with some accuracy, and the most favorable determining factor is the constitution."

An excellent indirect confirmation of the above is afforded by the experiences of other domestic and foreign companies in connection with the tuberculosis mortality among their insured. Of these we may mention especially the heredity statistics of the Thule Life Insurance Company of Sweden.

(*To be continued.*)

Book Reviews.

Defective Children. Edited by T. N. Kelynack, M.D., Member of the Royal College of Physicians of London; Fellow of the Royal Society of Medicine; Medical Adviser to the National Children's Home and Orphanage; Hon. Physician to Mount Vernon Hospital for Consumption and Diseases of the Chest; Metropolitan Examiner for the David Lewis Epileptic Colony; Member Hon. Medical Consulting Staff, National Association for the Feeble-minded; Hon. Physician to the Ragged School Union; Editor of "Medical Examination of Schools and Scholars," "Tuberculosis in Infancy and Childhood," "National Health Manuals," "Human Derelicts," "The British Journal of Tuberculosis," "The Tuberculosis Year Book and Sanatoria Annual," "The Year Book of Open-air Schools and Children's Sanatoria," "The Child," etc. Price, $3.00 net. New York: William Wood & Company, 1915.

The rapid development of the system of medical inspection of school children has been a prelude to a more comprehensive phase of public health activity, namely, the prevention, cure, or mitigation of disease throughout the entire period of childhood. Interest in the defective child has passed beyond the statistical stage. The problem is now one of prophylaxis and of treatment. This forms the keynote of the present volume. Defective children are studied not from the viewpoint of technical methods of examination, of public health administration, or of educational supervision, but from the larger viewpoint of improving the physical and mental well-being of these children. The scope of the task is so broad that no one man can hope to master it. For this reason a large number of experts contribute their special knowledge to this volume which thus represents an elaborate symposium. The separate contributions are as follows: Defective children and the Co-relation of the Public Services, by E. W. Hope; The Mentally Defective Child, by H. C. Marr; Idiots and Imbeciles, by D. W. Hunter; The Epileptic Child, by A. F. Hewat; Criminal Children, by W. C. Sullivan; Paralytic Cripples, by W. R. Jordan; Tuberculous Cripples, by H. J. Gauvain; Defects of Vision, by N. B. Harman; The Deaf Child, by J. K. Love; Speech Defects in Childhood and Early Adolescence, by L. H. F. Thatcher; Spinal Defects in Young Subjects, by A. H. Tubby; Cardiovascular Defects in Children, by T. Fisher; The Rachitic Child, by A. S. M. Macgregor; Defective Growth and Development in Infancy, Childhood, and Youth, by Hastings Guilford; Defective Girls in Secondary Schools, by Catherine Chisholm; Defective Boys in Secondary Schools by J. Lambert; School Clinics, by L. D. Cruikshank; Dental Clinics for Children, by L. S. Shennan; Open-Air Schools and Residential Schools for Defective Children; Schools for Cripple Children, by R. C. Elmslie; Defective School Children in Scotland, by G. H. Brown and Kate Fraser; The Defective Child in Ireland, by J. D. Lindsay; Defective Children in Canada, by Helen MacMurchy; Defective Children in the United States, by W. S. Cornell; Defective Children in France, by L. Dufestel; Defective Children in Germany, by K. Biesalski, and Defective Children in Hungary, by E. Deutsch. The contributors to this volume are well known in their respective fields of work; the collective product of their pen is a substantial contribution to the science and art of child conservation. Appended to each article there is an ample list of references. The subject matter appeals not only to the pediatrist and general practitioner but also to the educator, the public health officer, the sociologist, the jurist, and the statesman. The volume is a mine of information presented in clear and terse literary style and available both for study and for reference.

Grundriss der psychiatrischen Diagnostik nebst einem Anhang enthaltend die für den Psychiater wichtigsten Gesetzesbestimmungen und eine Uebersicht der gebräuchlichsten Schlafmittel. Von Prof. Dr. Julius Raecke in Frankfurt a. M. Mit 14 Textfiguren. Fünfte vehrmehrte und verbesserte Auflage. Preis, Mk. 3. Berlin: Verlag von August Hirschwald, 1914.

We reviewed the fourth edition of this little compendium only a year ago. A fifth edition, appearing so soon, attests its popularity. It is based in large part on the writings of Binswanger and Siemerling. The writer also acknowledges the friendly assistance of the latter in his present revision. The book is increased in size by only three pages, and apparently received but few alterations to bring it up to date. As a compendium it is to be commended. If we were permitted to make a suggestion for a subsequent edition it would be to add a glossary of the more technical terms.

Contributions from the Psychopathic Hospital (Department of the Boston State Hospital), Boston, Mass., 1913.

While these "contributions" do not reveal much original scientific research, their publication is a step in the right direction. The eighteen physicians contributing the thirty-four articles contained are to be congratulated on their opportunities; and those who wish to be oriented on the possibilities of the psychopathic hospital will find in the volume several articles of interest.

Mental Medicine and Nursing. For Use in Training-Schools for Nurses and in Medical Classes, and a Ready Reference for the General Practitioner. By Robert Howland Chase, A.M., M.D., Physician in Chief, Friend's Asylum for the Insane; late Resident Physician State Hospital, Norristown, Pa.; Member of the American Medico-Psychological Association; Member of the Neurological and Psychiatric Societies, Philadephia. 78 illustrations; price, $1.50 net. Philadelphia and London: J. B. Lippincott Company, 1914.

The writer of this little handbook has been superintendent of a hospital for the insane for many decades. During that time mental medicine has undergone radical changes. The writer has endeavored to keep pace with these changes, at the same time retaining what he considers, probably, some of the helpful things of experience. He describes his book as an introduction to the study of nervous diseases, and this is what it may be considered to be. It comprises, at least, all that average nurses are able to grasp and perhaps a little more; and it falls short of being a textbook for physicians. Part I is devoted to a description of the central nervous system and neurosis; Part II, to a study of normal psychology; Part III, to the subject of general psychiatry; Part IV, to the special forms of mental disorder; Part V, to treatment; and there is an appendix on poisons, and a table of definitions. There are 78 interesting illustrations, chiefly of cases. The book is printed on excellent paper in very readable type. The style is clear and direct, and the book may be said to be practical and suggestive.

The Intensive Treatment of Syphilis and Locomotor Ataxia by Aachen Methods. By Reginald Hayes, M.R.C.S., etc. Price, 3s. 6d. London: Baillière, Tindall & Cox, 1914.

This little octavo volume of sixty pages summarizes the inunction treatment of syphilis. The author does not claim inunctions to be a rival to salvarsan, but gives to each its sphere and limitations. He presents the advantages and objections to inunctions and points out their superiority to other methods. The book deserves praise, if for no other reason than that it calls the practitioner from the easier paths of injection and ingestion to the more scientific and safer method of inunction.

Glaucoma. A Symposium Presented at a Meeting of the Chicago Ophthalmological Society, November 17, 1913. Edited by Willis O. Nance, M.D., President Chicago Ophthalmological Society (1913); Ophthalmic Surgeon, Illinois Charitable Eye and Ear Infirmary; Former Oculist and Aurist, Cook County Hospital; Editor, *Journal of Ophthalmology and Otolaryngology*, and Wesley Hamilton Peck, M.D., President Chicago Ophthalmological Society (1914); Former Professor Ophthalmology, Chicago Eye, Ear, Nose and Throat College; Assistant Surgeon Illinois Charitable Eye and Ear Infirmary; Ophthalmic Surgeon, Oak Park Hospital. Price, $1.50. Chicago: Chicago Medical Book Company, 1914.

The articles in this volume, of 151 pages, were contributed by Lieut.-Col. Robert Henry Elliot, M.D., Edward Jackson, M.D., John E. Weeks, M.D., George Edward de Schweinitz, M.D., Casey A. Wood, M.D., Francis Lane, M.D., E. V. L. Brown, M.D., Nelson M. Black, Frank C. Todd, M.D., and Albert E. Bulson, M.D.

The book presents a careful review of the subject up to the date of issue, and, coming as it does from men of large experience and recognized high standing in the profession, merits the careful consideration of all who are interested in this very important part of ephthalmology.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held April 1, 1915.

THE PRESIDENT, DR. WALTER B. JAMES, IN THE CHAIR.

National Quarantine.—The Council recommended that the academy authorize it, in conjunction with the public health committee, to hold a conference on the subject of national quarantine in New York harbor, with representatives of other bodies that might be interested. Dr. Reginald R. Sayre moved that this recommendation be approved. This was seconded and passed.

The Elective Localization of Streptococci Following Intravenous Injection, with Special Reference to Appendicitis, Ulcer of the Stomach, Cholecystitis, Rheumatic Arthritis, and Erythema Nodosum.—Dr. EDWARD C. ROSENOW of Chicago presented this communication which was illustrated by lantern slides. He said that a year and a half ago when he had the honor of speaking before the academy he demonstrated gross specimens and lantern slides showing: First, that streptococcus viridans when injected intravenously in rabbits, and occasionally in dogs, produced a form of endocarditis resembling chronic septic endocarditis in man, and that arthritis developed relatively rarely and pericarditis and myocarditis scarcely at all. Second, that the streptococcus isolated from the joints of cases of typical rheumatic fever when injected produced a form of endocarditis which tended to heal just as in man, and multiple non-suppurating arthritis, pericarditis, and not uncommonly myocarditis. Third, that when streptococci attained a certain grade of virulency, irrespective of their original source, they were prone to localize in the mucous membrane of the stomach of animals, produring ulcers which resembled those in man in that they tended to persist and perforate. Fourth, the lantern slides illustrated the transmutation within the streptococcus-pneumococcus group. Dr. Rosenow said he wished to show by means of the lantern slides that appendicitis, ulcer of the stomach, cholecystitis, rheumatic arthritis, and erythema nodosum were due in many instances to streptococci because they were so commonly found in the lesions and because they produced the respective diseases in animals when injected intravenously soon after isolation. Similar results had been obtained with streptococci isolated from various foci of infection (infection atria) at the time of the acute attack, as during exacerbations, but usually not later. This fact suggested strongly that the tonsils, pyorrheal pockets, and other foci of infection not only afforded the entrance way for the bacteria, but the very conditions which he had shown in his transmutation work to be favorable for the acquirement of new properties of streptococci. Thus streptococci from appendicitis, on isolation, produced in the appendix in 41 out of 59, and after cultivation in only three out of 22 rabbits; streptococci from ulcer of the stomach, on isolation, produced ulcer in 50 out of 79, and after cultivation in no instance in 17 animals; from cholecystitis, on isolation, in 22 out of 27, and after cultivation in only one out of 12 animals, and from rheumatoid arthritis, on isolation, arthritis developed in 47, endocarditis in 33, myocarditis in 31, and pericarditis in 19, out of a total of 71 animals, and after cultivation this affinity had largely disappeared as shown in 14 animals injected. The strains from erythema nodosum produced similar results. The lesions in other organs were either entirely absent or slight in a large percentage of the animals.

Dr. W. T. LONGCOPE said that he was sure all had been extremely interested in the fine presentation which Dr. Rosenow had made of this important and complete study of experimental streptococcus infection. It was hard for anyone who had not an intimate knowledge of such work to realize the intricacies and difficulties of such a problem, and particularly the complicating factors which entered into the special problem of the localization of infection in disease. Formerly, of course, it had always been supposed that the body was itself in one way or another largely concerned in the localization of any infection. For a long time it had been assumed that an injury to any tissue made that tissue less resistant to infection and predisposed to localization of such pyogenic organisms as staphylococci and streptococci in that situation. With more complicated infections it had been shown that localization of the infecting organism depended upon the fact that certain fluids of the body were devoid of substances destructive to the infecting agent. This was particularly true of infection of the spinal meninges. Apparently the organism of poliomyelitis was rapidly destroyed by all the tissue juices and body fluids, except the spinal fluid. Consequently when the infection took place, though the entire body might be at first permeated by the infecting organism, the disease developed only when the organism reached the undefended spaces in the central nervous system. This adaptation between the infecting organism and the tissue of the host must, of course, vary in different infections, and it was evident that the properties of bacteria might change during their growth on artificial culture media or their repeated passage through animals; in the one instance the invasive power and pathogenic property of the organism diminished and in the other it was increased. But the development of such a highly specialized power of localization on the part of bacteria, which Dr. Rosenow demonstrated in these experiments, was of course entirely new and placed the subject in a most interesting light. If further experiments were to confirm these observations and show that the localization of infection depended to such a large extent upon the change in the organism which was brought about by its environmental development, this would prove a great advance in the study of infectious processes. They should be specially thankful to Dr. Rosenow for bringing before them such interesting and important observations.

Dr. RUSSELL L. CECIL said that J. Koch had shown that in typhoid cholecystitis the infections of the gallbladder were hematogenous in origin, due to lodgement of typhoid bacilli in the terminal capillaries of the mucosa. As far back as 1901 Adrian produced appendicitis in rabbits by intravenous injection of streptococci, pneumococci, straphylococci, typhoid bacilli, and colon bacilli. Recently Poynton and Paine had produced appendicitis in rabbits by intravenous injection of a streptococcus isolated from the joints in a case of rheumatic fever. Dr. Cecil thought that Dr. Rosenow's experiments added more evidence in favor of the hematogenous infection.

Dr. LUDWIG KAST said he wished to apologize for opening his remarks with a rather commonplace statement. We knew that different microorganisms in the bacteriological laboratory showed a predilection for different culture media. We also knew that different microorganisms showed different selective tendencies in their localization in the different organs of the human body. It was to the credit of Dr. Rosenow to have shown, as his experiments seemed to indicate, that at different times the same organism might manifest different selective tendencies, and furthermore, that it was possible to determine from the particular phase or stage of transmutation of an organism what its selective tendency was at that particular moment. The effect which these discoveries had upon our clinical conceptions seemed very far reaching. About twelve years ago, when Professor Pribram in Prague collected material for his monograph on rheumatism, he went through the records of post mortem examinations at the Pathological Institute in Prague, and determined in over 15,000 cases what the relation was between affections of the joints and affections of the heart valves. It seemed quite evident from these post mortem examinations that in one group of cases changes in the joints, severe or not severe, were associated with affections of the heart valves, whereas in another group of cases, particularly the deforming type of rheumatism, the heart valves were very rarely affected. In the light of the knowledge of that time it was justifiable to assume that these two groups represented two different clinical entities; that they were, in all probability, due to two different etiological factors. In the light of the knowledge which Dr. Rosenow's experiments seem to offer, it was plausible to assume that both groups of cases might be caused by the same organism in its different phases of transmutation. There was another side to this problem: When they spoke of selective localization of microorganisms, they must bear in mind also the selective attraction of different organs exercised upon the microorganisms. In other words, they could not deal with the problem of selective localization without dealing with the problem of the varying degrees or qualities of immunity of the different organs of the body. When a predilection was shown for the joints, the endocardium, the pericardium, and the tonsils, it might be that such predilection was purely a quality of the microorganism. On the other hand, it might be that there were certain qualities in these tissues—certain chemical qualities—

which predisposed them to the attack of the microorganism—invited the settling of the microorganism, so to speak. From the latter viewpoint, the problem became to a great extent a question of local immunity and of the chemistry of the different organs; and for this viewpoint they had chemical analogies: the phenomenon of ochronosis, for instance. An injection of the substance would color black the joints, the cartilages, the tendons, the endocardium, and the intima of the blood vessels. The predilection for these tissues seemed to be related to the fact that chrondroitine sulphuric acid was present in these tissues, whereas it was not present in others. The fact that there were such chemical similarities in different groups of organs in the human body had also another meaning. It seemed plausible to assume that a primary focus in the mouth might produce toxines which, carried by the circulating blood to the different parts of the body, would themselves show a selective action in fields remote from the primary infection. In other words, a peridental abscess might, through its toxines, affect the joints much as they would be affected if a secondary localization of the microorganisms in the joints had taken place. This would pertain particularly to those cases in which, without the presence of any microorganism, structural changes had occurred which were similar to those produced by direct action of the microorganism. Furthermore, such thoughts opened, possibly, a perspective in the field of therapy. Considering the work of Abderhalden on the specific defensive ferments of individual organs, one was tempted to think of the possibilities of a therapy which would help us, when the defenses of the body as a whole were in good condition, to overcome specific localized infections.

Dr. JOHN A. HARTWELL said that Dr. Rosenow had submitted the necessary evidence from an experimental point to show that intravenous injections of streptococcus could produce definite lesions in the gall-bladder, stomach, and appendix similar to the lesions seen in these organs clinically. In all cases large doses of the culture were used, and while there was a very evident selective preference of the various strains for the organ from which the strain had been isolated, there were also various other lesions produced. In some cases the dose employed seemed to have proved fatal. A long period of observation would be required to determine that the clinical lesions occurred as the result of a blood-borne infection, and that the selective action was equally definite. The lesion in the stomach differed quite markedly from the chronic indurated lesions seen in human ulcer. It was also difficult to see why multiple ulcers in the stomach were not more common if one assumed that streptococci in the blood were the exciting cause. Even granting a selective action, there was no explanation as to why many foci of ulceration did not often appear unless they limited the selection activity to a very circumscribed portion of the stomach. It was further a little difficult to accept a selective activity which showed a preference for a definite portion of the gastrointestinal tract or gall-bladder in man, dogs, rabbits, and guinea pigs. The nutritive chemistry of these various animals would seem to be further apart than those existing in various parts of the same animal. While, therefore, the experimental evidence as given by Dr. Rosenow was very convincing, there were many clinical factors that needed further elucidation. Confirmatory study from many workers could alone yield answers to all the questions which arose from a study of Dr. Rosenow's interesting work.

Dr. FENTON B. TURCK said that lesion of the stomach or duodenum following the intravenous or subcutaneous injection of cocci or bacteria usually appeared in the solitary lymph follicles. These small aggregates of lymphoid tissue acted as excretory channels and were identical with Peyers patches in the small intestines. Toxins, as well as bacteria injected, produced an inflamed appearance and remained so for some time, of an elevated irregular ring with central indentation, giving the resemblance of a peptic ulcer. On microscopical section, it might show smaller or larger collection of lymphoid cells with some necrosis and perhaps round cell infiltration, but they all healed up. This was not peptic ulcer nor the origin of peptic ulcer. On microscopic section of stomach or intestinal wall, many animals, especially dogs, normally showed a redundance of connective tissue, especially in regions of lymphoidal tissue. This, with fold or dipping down of the mucosa and submucosa and some necrosis, might be mistaken for chronic ulcers. The lantern slide shown illustrated this, and he thought more careful controls might show agreement with Bensley and also Carlson views, who had especially emphasized this source of error. Holman's objections to the elective infection of streptococci were based on the fact that owing to the ease with which streptococci entered these tissues from the normal intestine or respiratory tract, isolation of streptococci from these animals could not be used as proof that they were the same as those injected. He further showed that intravenous injections of bacteria brought about invasion, particularly streptococci derived from the normal alimentary or respiratory tract. It had been supposed that much local damage might be brought about by the streptococci of certain strains, but the careful work of Canavan and Southard questioned the effect of cocci forms which they say might produce some irritative effect but no destruction. Injury to the blood vessel by the streptococci might be inferred as indirect cause of many lesions, but Klotz found that in twenty cases of infection causing destructive effect upon the blood vessel, ten of the series were caused by the colon group of bacteria, five from pneumococci, and only three from streptococci. Proskauer reported a case of purulent peritonitis which showed streptococci and caused death without perforation of an ulcer or mesenteric gland. The paratyphoid bacilli were obtained in culture from many typical ulcers found in stomach and duodenum but no streptococci. No agglutination with streptococci—only with the paratyphoid bacilli. These typical peptic ulcers might have been interpreted as a streptococcus infection perhaps originating from the mouth. The conclusions of Koll, David, and others showed that 90 per cent. of kidney infections were due to colon group of bacteria, and chronic constipation was given as the direct etiological factor in kidney as well as appendicitis and gall-bladder diseases. In 1895 he published the result of three years' bacteriological work on cases indicating some relation of the mouth, nose, and throat to gastric disease. This lead to a more definite study of intestinal flora in relation to lesions of the stomach and duodenum. His work on the etiology of ulcer in relation to the colon group of intestinal bacteria in symbiosis was still in progress. Part of the work had already been published, with the confirmation from the work of others. The accumulating evidence of surgeons operating all over the world who found few of these cases in the non-meat eating, hygenically moderate eating, non-constipated individuals. His own recent studies indicated that the intestinal flora played an important rôle in the etiology of peptic ulcer. Recent developments showed that the bacteria passed into the submucous tissue and were there destroyed, and by their destruction created alteration in the circulation, a reduction in the antiferments, and finally, as the process continued, ulcers were formed in all the various stages depending upon the factors that permitted either constant or periodic invasion from the intestinal lumen. That streptococci could also accomplish this in symbiosis he had already shown, but they could not exclude the constant effect of the ubiquitous colon group of bacteria. The specific, elective, solitary etiological factor assumed by streptococci in all these diseases, as an hypothesis so brilliantly presented by Dr. Rosenow, must be met by thoughtful consideration and careful control work.

Dr. ROBERT T. MORRIS said that bacteria were simple morphologically but highly organized chemically, and changes produced by them through selective affinity related to the chemistry of their peers, the organic body cells of the particular structure which was involved. It was important to know if mutant varieties of a species remained as fixed variants, and in that case, if they might be called new species. If they returned to "ancestral type" under a new set of conditions they were given the key which opened a very large question in biology. It was extremely important for them to know if the mutant with special affinity for the appendix retained that characteristic through several generations, or if it would revert to the type which showed selective affinity for duodenal structures. Dr. Rosenow's work suggested the thought that Darwinians, Mendelians, and Eugenists might begin their basic studies from streptococcus viridans, which underwent mutation into several variant forms having the clinical value of species and then might return to "ancestral type," all in the course of a couple of weeks.

Dr. ROSENOW, closing the discussion, said he feared from some of the remarks made by some of the men that he had given the impression of not desiring to give due credit to men who had done work in these respective fields. He assured them with all his heart that this

was only apparent on account of the large amount of ground necessary to cover in so short a time. Full credit would be given in the publications. He fully realized that colon bacilli had been isolated from ulcer of the stomach after death and that ulcer of the stomach had been produced experimentally with colon bacilli, but that colon bacilli had much to do with the etiology of especially chronic ulcer of the stomach in men did not seem likely because he had succeeded in finding it only once and then in only small numbers in one of a series of ulcers removed during life at operation. The inability of a number of workers to verify his results on the transmutation of streptococci and pneumococci was clearly due, it seemed to him, to the fact that they had not followed closely his technique. Since the publication of his paper on this subject he had made many observations which supported the idea and he was more convinced than ever that his contentions, as voiced in his original paper, were correct.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, Held February 15, 1915.

THE PRESIDENT, DR. THOMAS S. SOUTHWORTH, IN THE CHAIR.

Presentation of Roentgenograms Illustrating Various Conditions.—Dr. JOSEPH FRIEDMANN gave this demonstration, which included a number of rare cases and others in which an obscure diagnosis was cleared up by means of the *x*-ray.

The Nagelschmidt Modification of the Kromayer Quartz Lamp in the Treatment of Diseases of the Hair and Scalp.—Dr. RICHARD W. MULLER read this paper (page 743).

Organotherapy in Chronic Disease, with Special Reference to Its Possibilities in Cancer.—Dr. HENRY R. HARROWER read this paper. He said that the mere fact that disease had been present for more than the proverbial forty days, and that a considerable proportion of chronic invalids perambulated from one doctor's office to another, as well as the fact that many widely differing forms of treatment were advanced from time to time, seemed to be convincing evidence that the treatment of chronic disease is still an unsolved problem, and hence worthy of persistent study. There appeared to be fashions in medical matters, just as there were in others, and apparently it was beginning to be the fashion to study and write about the internal secretions. From all sides there came evidences of profound interest in the subject, and in these days of advance in physiological and pathological research there had been gradually accumulated a fair knowledge of the series of organs which until recently had been almost entirely unknown. We had learned that the ductless glands exercise an intimate control over metabolism and the cellular activities, that in all probability this is brought about by definite chemical substances produced by these organs, the hormones, and by them conveyed to others by means of the blood and lymph; and, best of all, that it is possible to secure from animal glands certain active hormone-bearing substances in a more or less pure state which are available in the treatment of disease. None could now deny that certain of the ductless glands produce extremely active principles which have an equally powerful influence in the control of both normal and morbid phenomena. The organs of this class were concerned in what was now termed the "hormone balance," and this delicate balance, brought about by the interrelation of the internal secretions, was concerned not less in the maintenance of essential health than in the production of deviations therefrom. It might be stated as an axiom, he thought, that it was impossible for an individual to manifest the evidences of chronic disease without a corresponding disturbance in some or all of these hormone-producing organs; and, furthermore, he believed that many of those intractable symptoms-complex to which it was sometimes so difficult to give a suitable name were often aggravated by a disturbance of what had been termed the altruistic function of the cell. This function was one of extreme importance, for the cell itself might seem quite healthy, and yet gravely fail in this regard—thus serving to disorganize the delicate hormonic balance. Granting, then, that chronic disturbances were associated with general cellular inactivity, and that in certain conditions this deprived the body of essential stimuli, it must be obvious that the effective treatment of such conditions must include a consideration of the ductless glands and of means capable of re-establishing their normal functions. One of the most common disorders in which so-called "pluri glandula insufficiency" was evident was neurasthenia, and here pluriglandular therapy would not only serve to replace, to some extent at least, the missing secretions, but also favor an increased production of them by the homo-stimulant action which had been referred to. This seemed very plausible theoretically and practically it had been found to work well, although in this class of cases there was as yet no definite proof as to which of the ductless glands was deficient. Having referred to the functional neuroses and psychoses, many of which were now regarded as resulting from or being associated with disordered secretory action in certain of the ductless glands, the speaker said that many of the problems of the medical gynecologist had a purely endocrinous origin, and the metabolic disturbances of women constituted a large class of chronic diseases in which apotherapy was an extremely useful measure, as illustrated in the case of pituitary and extracts of the corpus luteum. One of the most neglected organitherapeutic remedies in gynecological practice, however, was mammary extract. The mamma was the direct antagonist of the ovary, and hence extracts from it might be of value in controlling conditions due to superactivity of the ovaries, such as menorrhagia, metrorrhagia and uterine fibroids. Personally, he had gathered together sufficient evidence in its favor to warrant the use of mammary extract in cases of fibroid for a period before operative procedures were undertaken, and to indicate that eventually this method of treatment would be held in much higher esteem than at present. The subject of organotherapy in chronic diseases was a vast one, and time did not permit but the barest reference to the use of thyroid extract in the well-known conditions associated with thyroid deficiency, or the advantages of pituitary extract in the equally chronic conditions of hypopituitarism. In connection with the relation of the glands of internal secretion to cancer, and the possibilities of opotherapy in this condition, certain well-substantiated theories regarding the disease might be mentioned: (1) Cancer is a chronic intoxication; (2) Its incidence evidences the lack of an element in the blood which permits cell proliferation at a point of particularly lowered resistance; (3) it is essentially a disease of senescence or, as termed by Gilford, "cell senilism." We knew that cellular activity is influenced by the harmones, or chemical messengers, that nutrition responds in a greater or less degree to their influence, and that it is possible to favor the reaction of the body against disease by the use of certain organic extracts. The questions naturally suggested themselves here: Is not cancer more than a chronic disease such as the more benign metabolic disturbances referred to? Is it possible to influence by means of opotherapy an unquestionably organic condition when the action of the endocrinous principles is supposed to be upon function rather than structure? Undoubtedly no form of internal medication at present known would destroy or remove the fundamental organic conditions pathognomomic of cancer; yet it was entirely possible that the resistance of the sufferer from cancer might be increased to such a degree that other measures in common use might be reinforced by an increase in the responsiveness of the cells and a general enhancement of nutrition. At present it could only be conjectured why some individuals presented a special receptivity to the implantation and growth of cancer cells and how these cells became implanted, but he believed that the day would come when it would be found that the disease was much more intimately associated with the internal secretions than was now generally supposed, and that quite probably it would be shown that the hormones may be very intimately concerned in its prevention and cure. If it were admitted that an important factor in all cancer cases was chronic cellular intoxication, obviously a part of the treatment consisted in favoring the activity of the known detoxicating organs, as well as removing all nidi of further trouble, chiefly, of course, in the alimentary canal. The thyroid-prathyroid apparatus was intimately concerned in the destruction of toxins, and in the literature there were a number of references to the fact that in cancer subjects the thyroid is usually found to be more or less atrophied. Indeed, thyroid underfunction was much more common than had until recently been believed, and it was entirely possible for the thyroid cells to be seemingly nor-

mal, and yet be failing very materially in the production of those substances responsible for carrying out the "altruistic" work of this gland. One of the well-known manifestations of the cancerous cachexia was achlorhydria and the resulting digestive disabilities, and for this reason it might be recommended as a reasonable procedure in all cases of cancer to attempt to re-establish the activities of the digestive glands by the adthe blood of the cancerous was not yet established, although the researches of Abderhalden and others inministration of secretin. Just what was missing from dicated that a definite series eof substances might be concerned in the matter. The missing element would, very likely, be found to be produced by the endocrinous system, and if this were the case our therapeutic possibilities would be increased, since we now knew with considerable certainty that when there is a functional hypoendocrinism or reduction in service to the body of certain of the secretory organs, not only can the missing substances be replaced, but the semiactive organs may be stimulated by certain organic extracts, in accordance with Hallion's law of homostimulation. The spleen and thymus appeared to offer greater possibilities than many of the other glands, although it seemed probable that eventually the optimum preparation would be a pluriglandular extract containing these and other synergists. The clinical findings of Little of Rochester, N. Y., warranted the use of several organic extracts, particularly those from the pituitary, parathyroid, adrenal cortex, and the islands of Langerhans. In his most recent paper, in addition to emphasizing the value of sugar feeding in many cases of cancer, Little had settled down to three glandular extracts as essential; total pituitary extract for the ectodermic variety of cancer, extract of the adrenal cortex for the mesodermic, and an extract of the pancreas rich in the islands of Langerhans for the endodermic. From the clinical results of his work one could not but be convinced that they warranted the continued investigation of the subject by a much larger number of students. The third postulate mentioned concerned the relation of the incidence of cancer to senility, and, according to Gilford, certain somatic cells became dead while the tissue around them was still in a state of comparative youth. These expressed their senility by returning to a more embryonic form, and as they did so they increased in number, the faculty of proliferation being one of the manifestations of regression. These senile changes might be presumed to be connected with disturbances in the harmone balance. Unquestionably in cancer there was a definite hypoendocrinism, and attempts to modify this, while possibly without specific effect upon the cancer itself, might be of assistance in modifying other accompanying conditions. Altogether, the possibilities of various pluriglandular combinations were almost without number, and suitable combinations might be given impirically where a more or less obvious deficiency was presumed. In such cases pluriglandular therapy was helpful whether they were in the cancerous or precancerous stage, and such a procedure would eventually attain a much more extended usefulness. The whole subject was not only of great theoretical interest but also undoubted practical value, and therefore deserved to be studied with renewed assiduity now that the matter of the internal secretions and the hormones were beginning to receive the attention of which it was so worthy.

Dr. Robert T. Morris said there could be little doubt that the medicine of the coming century would be the medicine of "home rule." Empirical remedies would be done away with more and more, and we would depend upon the resources of the system itself. As to one of these organic extracts, pituitary, it had been found for a time that it did not accomplish all that was expected of it; but when it came to be administered intravenously it was seen that it could do its work very rapidly and very efficiently. The technique was therefore a matter of importance. In certain cases of uterine fibromyoma thyroid extract had appeared to be curative, while in others it did not seem to have any effect. In regard to the relation of the tests to neuroses and psychoses, everyone from Hippocrates to Freud had had something to say, and we now believed that in dementia præcox the lipoid cephalin has lost its oxygen-carrying power because of injury from abnormal sex cell secretion. Dr. Harrower had referred to the colloidogenic function of the spleen, and in Nature the interchangeability between colloids and crystalloids was exceedingly interesting. The jelly-fish and other low organisms, although without alimentary tracts, were able to maintain their activities simply by the absorption of colloids and crystalloids from sea water, and the soft-shell crab could in the space of a few hours assume its hard mineral shell in consequence of the absorption of calcium salts which had not previously been contained in its economy. If such elaborate processes were conducted under the guidance of hormones, we might well assume that application of hormones in a therapeutic way would require a more profound knowledge of physiology than that to which we had as yet attained. If Dr. Harrower could produce five well-authenticated cases of cancer cured by organotherapy, the surgeons would refrain from operating in cases of this disease until he (Dr. Harrower) had had an opportunity to try out gland extracts.

Dr. William Seaman Bainbridge said that at present the whole subject of organotherapy must be regarded as *sub judice*. Great praise should be given those who had been and were making a special study of the internal secretions; but no subject, to his mind, was more full of pitfalls. He recalled that when he was studying medicine more than one of his professors pronounced Brown-Séquard a quack; so, too, the so-called quack of to-day might be the honored scientist of tomorrow. In this field what was still needed was more extended laboratory research and the correlation of the findings of this with clinical work. He could not agree with Dr. Morris that five cases of cure of cancer would be a sufficient test of any method of treatment for that disease. Many illustrations might be cited of alleged cures of many times more than five cases treated by reputable physicians, and pronounced by them cured, by methods which further test proved to be totally inefficient and perhaps entirely worthless. There seemed always to be within the ranks of recognized medicine certain enthusiasts whose credulity outweighed their judgment, and who could see curative merits even in such remedies as the notorious "Mattei electricities," the indisputable efficacy of which was proclaimed by Mother Ballington Booth upon her death bed; yet which proved, upon analysis, to be nothing but distilled water and inert coloring matter. The entire subject under discussion called for "watchful waiting."

Dr. Siegfried Block said that in Dr. Harrower's paper, so full of facts and suggestions, we had had the rare privilege of getting something which was really new. From the neurological point of view it might be said that we were gradually getting away from old obscure terms, and each year fewer cases were diagnosticated as functional disorders. The old term neurasthenia was one used to express a condition with indefinite and multitudinous symptoms, the best definition of which was that "the doctor can find no trouble and does not know the ailment present." When we realized that any chronic disease carried with it exhaustion neuroses to some degree, we at least knew that something was not being supplied to the economy in the way in which it was during health. This was the case in cancer, and the physical and mental wasting associated with this disease was to his mind quite as important as the growth itself. It was well known that with the stoppage of the sex glands in the female neurasthenic symptoms were met with. It made no difference whether this was by means of the menopause or of oophorectomy, cancer was liable to start up at this time. In certain persons there existed a predisposition to cancer, and in certain persons a predisposition to neurasthenia, and it was possible for both to be found in the same individual. The beginning of cancer was painless, and he had had at least one patient consult him for the nervous symptoms associated with the condition, in complete ignorance of the fact that cancer was present; and probably many others had had similar experiences, the nervous symptoms being the cause of the first visit to the physician. We should not be too enthusiastic in regard to organotherapy until more research work had been done on the ductless glands. All cases which were not bacterial or not traumatic in origin were not necessarily glandular. He was of the opinion that certain lymph glands have special functions to perform—for instance, the epitrochlears in syphilis and tuberculosis. Especially in the diagnosis of syphilis they furnished such great aid that a special function might be thought of; possibly they manufactured a special antitoxin selective in character. Another curious fact was that the *x*-ray at times arrested the growth of cancer and also put a stop to testicular power. Both these actions, however, were often only temporary. In actual experience he had seen only one case of cancer in which benefit had apparently resulted

from the use of organic extracts. A woman who had been suffering for the past four years from a large carcinoma of the breast had been treated, in addition to the employment of the *x*-ray, with thyroid, ovary and thymus extracts, in doses of five grains each, for weeks at a time. Although during the past year there had been no improvement in her condition, she was at least very little worse than before. She was also getting much less morphine now than formerly. The growth had remained about the size of a baby's head, and the fact that the patient was still living, while the progress of the disease had been so slow, seemed to point to a favorable influence exerted by the pluriglandular extracts. In no other cancer case had he observed any result at all from their use. It might be of interest to mention that in tertiary syphilis with such conditions as sclerosis of tracts of the cord the results of the administration of thyroid and thymus extracts combined, five grains of each, were often surprising. He would like to ask Dr. Harrower whether he had found much more benefit from fresh extracts than from tablets made by a reliable manufacturer. Some observers had claimed that the former were preferable, and personally he had found the fresh capsules more expeditious in their effects. In cases of cancer, glycosuria was often met with, and, so far as he knew, no reason for this had been given. Perhaps some relation of the thyroid and the pancreas, or possibly the adrenals, might explain it. It was now generally acknowledged that the thyroid and pancreas were dependent upon one another for proper action.

Dr. Samuel G. Tracy said he would like to know whether any actual cures had been effected by means of these organic extracts; so far we had heard nothing but theory on the subject.

Dr. Harrower, in closing, said that as to the efficacy of thyroid extract in certain cases of uterine fibroids, this, it seemed to him, might be explained by antagonism which undoubtedly existed between the thyroid and the ovaries, just as it did between the mammary glands and the ovaries. These fibroid growths were beginning to be regarded as an expression of hyperophorism. The pitfalls of this subject to which Dr. Bainbridge had alluded were offset, he thought, by the vistas of encouragement so frequently seen. Brown-Séquard, far from being a quack, had been one of the two men who had contributed most largely to our knowledge of the internal secretions and opotherapy. As to research work on this subject in laboratories, it was his opinion that while this was naturally of great value, at present it was not so much needed as clinical work by practising physicians. In regard to the matter of glycosuria in cancer, Little had found that cancer patients have hyperglycemia, but rarely glycosuria. Every case of coincident cancer and glycosuria, or of glycosuria followed by cancer, where he could verify the facts by autopsy or otherwise, showed that the pancreas was involved. The relation of the islands of Langerhans to diabetes was generally accepted, and, this being granted, failure of the islands resulted in diabetes or cancer or both, depending on various other factors. According to this theory of Little, if cancer were the result, such cancer should occur in endodermic tissues, since the islands were of endodermic origin. He could not say whether fresh glandular substance was of greater therapeutic value than the tablets on the market, but he had always found the latter satisfactory if they had not been kept too long. The endocrinous system, it would appear, was not confined to the ductless glands. It had been asserted by Blair Bell that every cell in the body might be an internal secretory organ, and Wright had expressed his conviction that the opsonins must be considered as products of the endocrinous glands. In regard to the efficacy of the glandular extracts in cancer, all that had been claimed in the paper was that they serve to ameliorate the condition and relieve pain; thus offering an encouraging field for both speculation and useful practical application. As to their curative effects, the results obtained by Little, Bazzoche, Billard, and others might be cited.

Philadelphia Neurological Society.

At a stated meeting held April 23 Dr. Williams B. Cadwalader exhibited "A Case of Cerebellar Diplegia." The patient was a boy six years old who from an early time in life presented difficulty in walking of an ataxic-spastic character, without sensory disturbances, ocular phenomena or marked change in reflexes.

Dr. George E. Price presented a patient exhibiting "Arteriosclerosis with Symptoms Resembling Pseudobulbar Palsy of Gradual Onset." The case occurred in a man 62 years old who for five years or more had increasing difficulty in locomotion, with thick speech, in conjunction with evidences of sclerotic changes in the vascular system.

Dr. John H. W. Rhein exhibited "Two Patients, Brothers, with Chronic Contractions of the General Musculature." One was 39 years old and the other 37. The disorder had existed in the one for 19 years and in the other for 18 years. Besides, two other members of the family presented similar symptoms. The patients presented a constant jactitation, involving practically all parts of the body, increased by observation and emotional influences, but without spasticity or contractures or noteworthy alteration in the reflexes. One of the cases had previously been presented to the Society first as a case of pseudosclerosis and at a later time as one of lenticular degeneration.

Dr. Rhein presented also "A Specimen Showing Multiple Sarcomata of the Brain," and also "A Specimen of Tumor in the Cerebello-pontile Angle." With respect to the latter it was known that the patient had presented disorder of locomotion and the tumor was found to be easily separable from surrounding tissues.

Dr. Ezra Allen presented a communication entitled "A Study of Cell-division in the Cerebellum and Demonstration of a New Technic for Staining Mitotic Figures."

Dr. Milton J. Greenman presented a communication entitled "Regeneration of Peripheral Nerves." It was found that following section of the peroneal nerve in lower animals there occurred in the course of regeneration an increase in the number of nerve-fibers at the point of division and subsequent union and for a short distance distad and peripherad, although the nerve itself had become smaller. In addition the corresponding nerve on the opposite side of the body in the same situation also was reduced in size, although there had been no symptomatic indication of disturbance of function on the unoperated side. It was further found that when the extremities of the divided nerve were surrounded by a tube of celloidin the increase in the number of nerve fibers was markedly less.

Dr. G. Hudson Makuen presented a communication entitled "The Psychology of Stammering." He accepted the view that stammering is an expression of auditory amnesia and exhibited illustrative cases showing the results of education and training.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

State Board of Medical Examiners of New Jersey.

October, 1914.

(*Concluded from page* 882.)

OBSTETRICS.

1. Give average normal pelvic measurements which you would take at examination of a woman in her first pregnancy. Give smallest measurements which would permit natural delivery.
2. Give mechanism of second stage of labor in L. O. A.
3. Give treatment of different degrees of uterine inertia.
4. Give three causes for postpartum hemorrhage, and treatment for each.
5. Give management of shoulder presentation.
6. Give causes for non-engagement of head at brim, and give management of each condition.

GYNECOLOGY.

1. Name two conditions in which cystoscopy would aid in diagnosis, and give cystoscopic findings in each.
2. Differentiate subinvolution of uterus, chronic metritis, and uterine fibroid.
3. Give history and symptoms of tubal pregnancy in third month, and its possible terminations.
4. Give blood supply of the uterus and ovaries.

SURGERY.

1. Define a compound, comminuted, and complicated fracture. Give treatment.

2. Give diagnostic symptoms and treatment of acute epididymitis.
3. Give diagnostic symptoms of stone in ureter.
4. Describe the deformity and the method of reduction of the same in Pott's fracture.
5. Describe congenital dislocation of the hip.
6. What conditions may give rise to symptoms simulating those of appendicitis?
7. What is the clinical aspect of a beginning carcinoma of the female breast?
8. Define hernia; give different varieties of abdominal hernia.
9. What are the symptoms produced by gallstones?
10. Define and give symptoms of hypothyroidism.

ANSWERS.

OBSTETRICS.

1. The diameters and measurements of the female pelvis are easily remembered from the following table:

	Antero-posterior	Oblique	Transverse
Brim	4 inches	4½ inches	5 inches
Mid-plane	4½ "	4½ "	4½ "
Outlet	5 "	4½ "	4 "

In external pelvimetry four measurements are generally taken: (1) between the anterior superior spines of the ilium, normally about ten and a quarter inches; (2) between the external edges of the iliac crests, normally about eleven inches; (3) between the heads of the two great trochanters, normally about twelve and a quarter inches; and (4) between the spinous process of the last lumbar vertebra and the upper margin of the anterior surface of the symphysis pubis, normally about eight inches.

"The *conjugata vera*, or true conjugate, is measured from the center of the promontory of the sacrum to that point on the posterior surface of the upper end of the symphysis pubis which is crossed by the iliopectineal line. This is the shortest diameter at the brim through which the head must pass. It cannot be accurately measured, but is estimated in the normal pelvis at 10.5 to 11 centimeters (4¼ to 4½ inches). The *diagonal conjugate* is measured from the summit of the subpubic arch, or the subpubic ligament, to the promontory of the sacrum; it is from this diameter that we estimate the true conjugate. To estimate the true conjugate from the diagonal, we deduct from ½ to ¾ of an inch (1.5 to 2 centimeters). The amount to be deducted depends (*a*) on the depth of the symphysis pubis—the greater the depth the greater must be the allowance; (*b*) on the thickness of the pubic symphysis, for increase in the thickness increases the allowance to be subtracted; (*c*) on the inclination of the symphysis and the inclination of the brim of the pelvis, for when the promontory is high a greater deduction must be made."—(Polak's *Manual of Obstetrics.*)

The smallest conjugate diameter which will permit of natural delivery is probably about three inches.

2. *Mechanism of Labor in L. O. A.*—"(1) Accommodation of the size of the fetal skull to the size of the pelvic canal by flexion; accommodation of the shape of the fetal skull to the shape of the pelvic inlet by moulding; accommodation of the direction of the head to the direction of the pelvic canal by lateral inclination. These movements occur prior to labor, when the head enters the pelvic inlet with the subsidence of the uterus. (2) Further flexion, molding, and accommodation of the head to the pelvis by lateral inclination, when labor-pains appear, and the head is subjected to a propulsive force and to the resistance of the lower uterine segment, the cervix, and the pelvic walls. (3) Dilatation of the lower uterine cavity and of the cervical canal. (4) Descent of the head to the pelvic floor, mainly by an extension of the fetal spine. The fetal body, as a whole, is not yet propelled along the birth-canal, because, during a pain and while the head is obviously descending to the pelvic floor, the fundus uteri and the breech do not sink to a lower level. On the contrary, there is a slight elevation of the fundus, and elongation of the uterus, and the distance between the head and the breech increases during a uterine contraction. (5) Anterior rotation of the occiput. (6) Propulsion and extension of the head in the direction of least resistance under the pubic arch until it is delivered, again following the direction of the lower pelvic floor, which is now upward, forward, and outward. (7) Restitution. The rotary movement of the head is not followed by the shoulders. As the former escapes from the vulva with the sagittal suture running anteroposteriorly, the neck is necessarily twisted. As soon as the head is released from the forces which compel its rotation, it immediately resumes its natural relationship with the shoulders, which lie with their long axis in the oblique diameter of the pelvis. (8) External rotation. This movement of the head is explained by the movement of the shoulders within the birth-canal. (9) Descent, rotation, and birth of shoulders. The anterior, or right, shoulder first strikes the resistance of the pelvic floor. In obedience to the universal law that whatever portion of the fetal body first encounters this resistance is directed downward, forward, and inward, the anterior shoulder is compelled to travel in these directions by a rotary movement of the shoulders on the spine. The anterior shoulder finally appears under the arch of the symphysis; unable to move further forward, the posterior shoulder and arm are propelled over the floor of the pelvis and are born, their escape being followed by the birth of the anterior shoulder and arm. (10) Delivery of remainder of the body by a movement so rapid that the eye cannot well follow it, the birth-canal being so widely dilated that its walls offer no resistance to the escape of the small and compressible thorax, abdomen, and lower extremities."—(From Hirst's *Obstetrics.*)

3. "*Treatment of uterine inertia:* Endeavor to ascertain and remove the cause. Place the woman under the best hygienic conditions. If the source of reflex disturbances cannot be removed, we may quiet the nerve center by chloral, opium, or the bromide of potassium, after which the inertia is commonly relieved. When the patient is suffering from fatigue during a protracted labor, quinine is of great use. Massage and stroking of the uterus through the abdominal walls may be tried. If over-distention exists we should early rupture the membranes."—(Landis' *Obstetrics.*)

4. POSTPARTUM HEMORRHAGE. *Causes:* Anything interfering with the firm contraction of the uterus after the expulsion of the child; retained placenta, or membrane, or clots; weakness of the uterine muscle; rapid labor; delayed labor; poorly developed uterine muscle; inflammation or disease of uterus.

Treatment: Grasp the uterus at once, through the abdominal wall, and massage it firmly. Anything in the uterus should at once be cleaned out. Pass one hand into the uterus, and with the other on the outside make firm pressure. A hypodermic of ergotin or ergot can be given by an assistant. An intrauterine douche of hot sterilized water (about 115° F.) may be given. Sometimes a very thorough packing and plugging of gauze of uterus and vagina may be necessary. Whatever is done must be done promptly; and everything likely to be needed for this emergency should be prepared beforehand in every labor.

5. In cases of *shoulder presentation*, if seen before labor, version should be performed to correct the malpresentation; in case of impaction a cesarean section is indicated; sometimes decapitation or embryotomy has been performed, but a cesarean section is preferable. Cases of shoulder presentation have been known to terminate spontaneously, but it is not advisable to rely on this possibility.

6. The chief causes are hydramnios, hydrocephalus, contracted pelvis, malpresentation.

"*Treatment:* Empty the bladder and rectum; determine if there is a faulty presentation, as bregma, brow, or face. Measure diagonal conjugate and height of symphysis and determine the true conjugate. If this latter measures less than 2¾ inches in a simple flat pelvis, or three inches in generally contracted pelvis, the contraction is absolute, and only cesarean section or craniotomy is possible. Ascertain by palpation whether there is serious disproportion between head and pelvis. Malpresentations must be corrected with one hand in vagina pressing upward on the fetal anterior portion of the presenting part, and if possible drawing down in the occipital pole, aided by external manipulation. Press the head downward into the pelvis; this maneuver may be aided by Walcher's position. If there is marked disproportion, cesarean section and craniotomy must be considered. If disproportion is apparently not insuperable, rupture the membranes just after the acme of a pain, when the cervix is fully dilated, keeping the patient in Walcher's position. If the head thereupon engages during the next few pains, allow spontaneous delivery, or aid with forceps, if necessary. If the head still refuses to engage, apply axis-traction forceps in Walcher's position, tentatively; if unsuccessful, perform podalic version by combined

or internal method. If membranes have already ruptured, note whether there is marked retraction ring. If not, podalic version is proper, subject to limitation of slight disproportion; but if the uterus has retracted markedly, forceps, and that failing, only cesarean section, symphyseotomy, or craniotomy is admissible."—(From Scott's *State Board Obstetrics.*)

GYNECOLOGY.

1. Tuberculous cystitis and gonorrheal cystitis.

TUBERCULOUS CYSTITIS.	GONORRHEAL CYSTITIS.
1. Located chiefly about the trigone.	1. Not at all so confined.
2. Inflammatory reaction zone absent or not well defined.	2. Clear inflammatory reaction zone, later changing to dull-brown color.
3. Tuberculous cystitis not common.	3. Common.
4. Characterized by presence of small tubercles situated about the trigone and ureteral orifices.	4. Characterized early by insular areas of reactive inflammation, with healthy or nearly healthy intermediate mucosa. Later insular areas may become confluent and extend over the whole mucosa.
5. No projecting tufts of pus.	5. Projecting tufts of gonorrheal pus are apt to be present. In chronic stage regions of elevation may be excavated by ulceration.
6. No subperitoneal extravasation of blood.	6. In very acute stage there is subperitoneal extravasation of blood.
7. Bacillus tuberculosis.	7. Gonococcus.

—(Dudley's *Gynecology.*)

2. In *subinvolution of the uterus* there will be a history of a more or less recent pregnancy, with prolonged labor or puerperium; the uterus is larger than normal, and there may be hemorrhage and leucorrhea.

In *chronic metritis* the uterus is uniformly enlarged, and is of uniform hardness; the enlargement is moderate; there is tenderness on pressure; generally there is a history of infection.

In *uterine fibroid*, the uterus may be enormously enlarged, the enlargement is irregular, and the fibroids are generally harder than the uterus; no tenderness on pressure; and no history of infection.

3. TUBAL PREGNANCY. "Prior to the fourth month the three cardinal and practically constant points in the diagnosis of beginning extrauterine pregnancy are (1) disturbance of menstruation, (2) sharp pelvic pain, usually accompanied with faintness, and (3) the presence of a mass adjacent to and connected with the uterus. Certainty of diagnosis is based upon a logical analysis of these three factors."—(Jewett.)

The *possible terminations* are: Rupture of the tube, followed by hemorrhage, shock, peritonitis, and perhaps death; tubal abortion; and continuance of the pregnancy to term.

4. *Blood supply of the uterus:* The uterine and ovarian arteries.

Blood supply of the ovaries: The ovarian arteries.

SURGERY.

1. A *compound fracture* is one in which an open wound extends from the seat of the fracture to the surface of the body.

A *comminuted fracture* is one in which the bone is broken into many fragments.

A *complicated fracture* is a fracture with the addition of some injury to neighboring structures, such as joint, artery, vein, nerve, or soft parts.

Treatment of simple fracture: "In simple fractures there are four essentials: (1) Reduction; (2) coaptation; (3) immobilization; (4) promote the nutrition of the part and prevent adhesions in the neighboring joints and muscles."

Treatment of compound fractures: "The most important thing is to render the wound aseptic by enlarging it and washing its depths and surroundings thoroughly with 1 in 20 carbolic or 1 in 500 biniodide. An anesthetic is nearly always necessary. Loose fragments should be removed, hemorrhage dealt with, and the bones fixed by wires or screws. The wound should be drained by a tube at the most dependent spot, and the rest of the wound closed. The limb should then be fixed on a splint, and in most cases will be found to do well."—(*Aids to Surgery.*)

2. "Acute epididymitis is characterized by swelling about the testicle, pain in the groin, and tenderness over the posterior part of the testicle. The pain becomes acute, swelling rapidly increases, and the constitution sympathizes. The swelling is due partly to engorgement of the epididymis and partly to fluid in the tunica vaginalis (acute hydrocele).

"*Treatment* by septic puncture with a tenotome, if fluctuation is marked, will relieve tension and pain. Leeching over the external abdominal ring, the use of an ice-bag, elevation, application of guaiacol, and administration of laxatives and opium constitute the usual treatment in the acute stage. Applications of guaiacol over the cord, epididymis, and testicle seem to relieve pain and distinctly lessen swelling. Two applications a day should be made for one week. At each application paint the scrotum and over the external ring with 15 drops of guaiacol in one dram of glycerin or olive oil. Strapping is employed as the inflammation subsides."—(Da Costa's *Surgery.*)

3. *Stone in the ureter* is characterized by: Severe colic, with pain radiating along the ureter; tenderness over the ureter; hematuria; the stone may be felt through rectum or vagina; a skiagram may show the stone; ureteral catheterization through the cystoscope may allow of the stone being touched by the catheter, and a waxed tip may receive a scratched impression.

4. *Pott's fracture* is very common, and is due to indirect violence, such as turning over on the inside of the foot. The strain tears through the internal lateral ligament of the ankle or tears off the tip of the malleolus; then the astragalus is pressed against the inner side of the external malleolus by the continuation of the violence. The fibula is overbent, and breaks about three inches above the tip of the malleolus. At the same time the foot is displaced outward or outward and backward. In many cases, however, the displacement is slight.

Treatment: "An anesthetic should always be given, and the fracture reduced by relaxing the calf muscles and applying traction to the foot. The limb must then be fixed on the back-splint, with side-splints in addition. The foot must be at right angles to the leg, the bony points in line, and the posterior displacement corrected. The surest way of maintaining the foot in good position is to at once apply plaster of Paris. Other splints used are Dupuytren's and Syme's horseshoe splint. Massage and passive movement at the end of ten days are advisable, the fragments being firmly grasped to prevent displacement."—(*Aids to Surgery.*)

5. "*Congenital dislocation of the hip* is usually due presumably to arrested development. It may be inherited. It occurs more frequently in females. It is seldom apparent until the child begins to walk. Rarely it occurs during birth due to cramped position of the child *in utero*. The dislocation results in atrophy of the acetabulum, the cavity becoming more and more shallow, and of the head of the femur which rests behind the acetabulum on the dorsum of the ilium. The neck of the femur and the thigh muscles are shortened. The capsule is stretched, an hourglass constriction sometimes being found between the head and the pelvic bone. In unilateral dislocation there is scoliosis and limping; in bilateral, there is a waddling gait and lordosis."—(*Pocket Encyclopedia.*)

6. *Symptoms simulating those of appendicitis* may be found in: Gastroenteritis, intestinal obstruction, typhoid fever, gastric ulcer, duodenal ulcer, salpingitis, ovaritis, kinking of ureter, renal colic, hepatic colic, ruptured extrauterine pregnancy, peritonitis.

7. *Clinical aspect of a beginning carcinoma of the female breast:* "Scirrhous carcinoma is usually met with in women between the ages of thirty-five and fifty, and it often begins while the patient is still menstruating regularly. It sometimes occurs in patients below thirty. The most common site is the upper and outer quadrant of the breast, but it may occur in any part of the gland. Sometimes there is more than one nodule in the breast. In its early stages the condition is quite painless, and the existence of the tumor is usually discovered accidentally. In some cases indrawing of the nipple or dimpling of the skin over the breast first attracts attention. It is often noticed that there is

a difference in the level of the two nipples, that of the affected breast being at a higher level than the other (Watson Cheyne). As the disease progresses the patient experiences a dull, aching pain, with occasional sharp twinges shooting through toward the shoulder, up into the neck, or down the inner side of the arm. On palpation, a more or less circumscribed and fairly well-defined tumor of stony hardness may be felt in the substance of the breast. Not being encapsulated, it cannot be moved apart from the breast. When firmly pressed against the chest wall with the flat of the hand the tumor becomes more evident, and its stony hardness is fully appreciated. The skin over the growth may for a long time remain free, but, as the disease progresses, it becomes tacked down, and is later dimpled by contraction of the suspensory ligaments of Cooper. When the skin becomes invaded by the tumor it assumes a characteristically coarse and indurated appearance, aptly compared to that of the skin of an orange or to pig's skin. When the tumor is near the center of the breast, it causes retraction of the nipple by dragging on the large ducts. It cannot be too strongly emphasized that the presence of all or any of these symptoms is not necessary for the diagnosis of cancer, and that when there is any doubt the patient should be given the benefit of an exploratory operation." —(Thomson and Miles' *Manual of Surgery.*)

8. *Hernia* is the protrusion of a viscus or other structure, either in whole or in part, through the cavity in which it is normally placed.

Varieties of abdominal hernia: Inguinal (oblique and direct; the oblique may be congenital, acquired, or infantile); femoral; umbilical; ventral, and postoperative.

9. The *symptoms of gallstones* are: *"Indefinite pains;* fullness in right hypochondrium and epigastrium. *Paroxysms of colic* begin in hypochondriac and epigastric regions, spread toward navel and right scapula; generally begin in daytime, during exercise, and last a few minutes to several hours; collapse, sickness, or vomiting. *Sickness and malaise,* quite independent of colic. *Vomiting.*—At end of paroxysm; bile-stained vomit; calculus is rarely vomited. *Collapse.*—Feeble pulse; clammy skin, low temperature. *Calculi in feces.* —Absence in some cases accounted for by stone having failed to reach the intestine. *Jaundice.*—Usually occurs 12 to 36 hours after colic; skin, urine, conjunctiva are yellow; feces are clay colored and offensive; rarely, and in old people, jaundice occurs without preceding colic; does not occur when stone is in cystic duct; is partial, *i.e.* feces contain bile when obstruction is partial, or when fistulous communication exists. *Temperature.*—Sometimes rigors, with temperature 103° or more, occur after colic; probably due to septic infection at seat of ulceration; fever may be of an intermittent type, associated with catarrh of bile-ducts and an impacted calculus; may be remittent, and lead on to septicemia or septic endocarditis; associated with suppuration in bile-ducts."—(*Synopsis of Surgery.*)

10. *Hypothyroidism* is the condition produced by absence or diminution in the secretion of the thyroid gland. The *symptoms* are: "(1) *Changes in the subcutaneous tissues.*—Great increase of fat and mucoid tissue; the hair is brittle and falls out; supraclavicular fatty masses are very conspicuous. (2) *Changes in the nervous system.*—Amentia or dementia are prominent; in the case of cretinism a state of childishness or imbecility continues throughout life unless the case is treated. (3) *Changes in the skeleton.*—The terminal phalanges become broad and spatulous; in cretinism growth is arrested, so that the stature of the adult is that of a child of about six. (4) *Changes in the genital organs.*—The cretin has undeveloped sexual glands, undescended testes, and no secondary sexual characters; in myxedema sexual feeling and power are lost."—(*Synopsis of Surgery.*)

Effect of Sarcoma Autolysates upon the Development of Sarcoma.—B. Morpurgo states that the injection of the autolysates of a sarcoma in a mouse from which part of the tumor has been removed has no effect in retarding the further development of the remaining portion of the growth. These autolysates have several times facilitated the attachment and development of sarcoma grafts in races little receptive to these grafts. They have no effect upon individual refractoriness to the latter. No effects are observed after the injection of sarcoma extracts in physiological salt solution.—*Archivio per le Scienze Mediche.*

Therapeutic Hints.

Tincture of Boxwood in the Treatment of Cholangitis.—A. De Vevey alludes to the apparent specific action of this preparation in the treatment of the so-called intermittent hepatic fever of Charcot. Tincture of boxwood is both cholagogue and purgative. It is given in doses of 5 grams.—*Bulletin Générale de Thérapeutique.*

Treatment of Post-typhoid Proctitis.—M. Loeper and P. Leroy recommend the use of the following suppositories:

℞ Ichthyol, 0.15 to 0.20 gram.
Tannin, 0.15 gram.
Extract of belladonna, 0.02 gram.
Cocoa butter, 3 grams.

One of these should be inserted into the rectum every evening.—*Progrès Médical.*

Antipyrine in Chorea.—Comby is credited with the following formulæ:

℞ Antipyrine, 10 grams.
Simple syrup, 190 grams.
Spirit of peppermint, 1 gram.

℞ Antipyrine, 10 grams.
Fluidextract of licorice,
Glycerine, aa 15 grams.
Water, q.s. ad 150 c.c.

The dose of either of the above is one tablespoonful three times a day.—*Riforma Medica.*

Lavage in Carbolic-Acid Poisoning.—D. J. Macht concludes from his experimental study that the efficiency of lavage in phenol poisoning depends on the quantity of poison taken, on the time after poisoning that the lavage is begun, and on the solution used for washing the stomach. A strong solution of sodium sulphate appears to be the most useful for the purpose; next in efficiency comes plain water. The influence of alcohol in phenol poisoning depends on the time of its administration. An animal that is previously intoxicated with alcohol can withstand better the effect of phenol taken afterward. On the other hand, alcohol administered to an animal after poisoning with phenol will aggravate the symptoms and hasten death. The use of alcohol in carbolic acid poisoning should be strongly discouraged.—*Bulletin of the Johns Hopkins Hospital.*

For the Lightning Pains of Tabes.—G. Rummo recommends the following:

℞ Acetphenetidine.
Methylacetanilide.
Quinine hydrobromate, āā 1 gram.

M. et div. in pulv., No. X. Sig.: Five or 6 powders to be taken in the course of the day.—*Riforma Medica.*

Treatment of Nervous Depression Following Influenza.—Sir Richard Douglas Powell has recommended the following in the treatment of sweatings associated with nervous depression following influenza in a patient suffering from congenital disease of the heart:

℞ Strychnine hydrochloride, gr. 1/3.
Dilute phosphoric acid, ♏ ij ss.
Tincture of belladonna, ♏ ss.
Tincture of digitalis, ♏ ss.
Syrup of orange, ʒ j.
Chloroform water, ad ʒ vi.

M. et Sig.: One tablespoonful in a wineglass of water at 10.30 A.M. and 3 P.M. It may be advisable to add twelve minims of the tincture of the chloride of iron at the time of taking.—*Clinical Journal.*

RECENT STUDIES OF PANCREATIC SECRETION.*

BY MAX EINHORN, M.D.,

NEW YORK.

PROFESSOR OF MEDICINE AT THE NEW YORK POSTGRADUATE MEDICAL SCHOOL.

THE pancreatic secretion being of paramount importance to life, it deserves our closest attention. In several other papers[1-3] I have given my experiences with the duodenal contents in man. In the present article I intend to embody my recent observations in this line.

A. Physiological.—It is well known that the pancreatic secretion contains a milk-coagulating ferment.

In the duodenal contents a similar ferment is found. The question arises, is this rennet ferment due to the pancreas or is it perhaps the rennet ferment of the stomach. In order to decide this point it was necessary to look for some points of differentiation between these two ferments, viz., the gastric and pancreatic rennets.

I accidentally observed that boiled milk did not curdle with the duodenal contents. I therefore investigated this point. The experiments with gastric and pancreatic secretions, mixed with boiled and unboiled milk (1 drop of either secretion to 1 c.c. of milk), are given in tables 1 and 2.

It is seen at a glance that the gastric juice coagulates milk, without any difference whether it be raw or boiled, while the pancreatic secretion (as found in the duodenum) curdles raw milk and not boiled milk, the latter remaining fluid for four to six hours. This clearly shows that the rennet ferment, found in the duodenum, belongs to the pancreas and is different from the gastric rennet.

There exist two more points of differentiation: (1) Gastric rennet curdles milk in from five to ten minutes, while the pancreatic rennet requires from twenty to sixty minutes to do this; (2) the gastric juice, made alkaline to phenolphthalein, loses its coagulating faculty for milk; the duodenal contents, made alkaline to phenolphthalein, retain their ability of curdling, milk.

The following experiments show this distinctly. (Tables 3 and 4.)

One drop of pancreatic secretion, as found in the duodenum, mixed with 1 c.c. of milk and left at blood temperature for twenty to twenty-four hours,

*Read before the American Gastroenterological Association on May 10, 1915, at Baltimore, Maryland.

very often shows almost an entire disappearance of the white milky color, the fluid now being watery or slightly straw colored and transparent. At times there is a small coagulum left at the side of the tube. The amount of coagulum left depends prob-

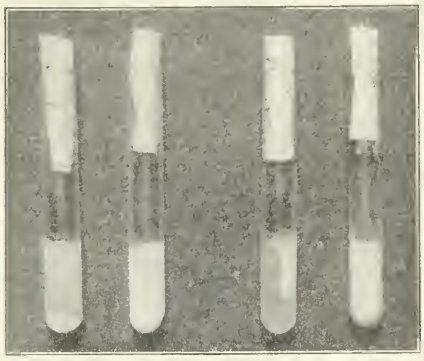

FIG. 1.—A Duodenal contents (patient S); B, gastric contents; each 1 part to 20 parts milk (*a*, raw, *b*, boiled), after 20 hours' digestion at blood temperature.

ably on the amount of trypsin present. This would make it possible to use milk as a coarse test for the presence or absence of trypsin. Boiled and unboiled milk show a great difference in their action with the pancreatic secretion, with regard to the amount of coagulum left undissolved after twenty-four hours, boiled milk showing a coagulum sometimes ten times as large as unboiled milk. (Table 5.) But this difference of boiled and unboiled milk with regard to its coagulum is also noticeable in its relation to the gastric juice (Fig. 1, A and B). Table 2 illustrates this fact.

TABLE V.—BEHAVIOR OF RENNET FERMENT IN DUODENAL CONTENTS, 1 DROP TO 1 C.C. OF UNBOILED AND BOILED MILK AFTER 24 HOURS, WITH RELATIVE AMOUNTS OF COAGULUM LEFT

No.	Date	Name	Amount of Coagulum	
			Unboiled Milk	Boiled Milk
1	III, 4, '15	Sh	+1 10	+2/3
2	"	F	+1 5	+1 2
3	"	S	+1 4	+7/8
4	"	Miss B	+1/8	+1/2
5	12	Br.	+1/5	+9/10
6	14	P	+1/10	+1/2
7	"	K	+1/10	+9/10
8	16	B	+1 4	+7/8
9	20	Kl	+1 8	+3/4

It appears from these experiments that unboiled milk is changed more thoroughly than boiled milk. The conclusion seems to be justified that unboiled milk would be easier for digestion than boiled milk.

Technique.—After these cursory remarks on pancreatic rennet and milk, I go over to the technique used by me for the determination of the three main ferments of the pancreas: amylopsin, steapsin, trypsin. In the last two or three years I have used one uniform method, so that comparisons may be made more easily and the results should be of greater value.

The method used is that of agar tubes, described by me[1] in the MEDICAL RECORD.

I shall here again state the procedure for making the tubes, which is as follows:

I. Starch Tubes.—Agar powder, 2.5; starch, 5.0; distilled water, up to 100.0. Rub the starch and agar in a mortar with sufficient water to make a smooth paste, then add the balance of the water. This mixture is put into a flask and heated to the boiling point. It is then drawn by suction into a capillary glass tube (inside diameter, 1.5 mm.) which has previously been warmed in the flame. The tube and contents are allowed to cool and are then cut into 3 cm. lengths. These are sealed at each end with melted paraffin.

II. Olive Oil Tubes.—Olive oil, 25.0; agar powder, 2.0; aqueous solution of nile-blue sulphate (1:2000), sufficient to make 100.0.

Rub the olive oil and agar together, add sufficient water to make a thin paste, then add the nile-blue-sulphate solution to make the balance of 100 c.c. Then proceed the same as with the starch tubes.

III. Hemoglobin Tubes.—Hemoglobin powder, 1.0; agar powder, 2.5; distilled water, sufficient to make 100.0.

Rub the hemoglobin with about 10 c.c. of water until it is smooth, add the agar powder and the balance of the water; then proceed in the same manner as with the starch tubes.

The agar tubes* are best kept on ice until used. They retain their efficiency for a month or six weeks, then they begin to deteriorate. They become dry and are apt to give wrong results.

Mode of Procedure.—Take one each of the starch, oil, and hemoglobin tubes, scrape off the paraffin at one end, and put them vertically into a bottle containing the duodenal secretion (Figs. 2 and 3). Add a few drops of toluol and keep the bottle at blood temperature for sixteen to twenty-four hours. The examination is made in the following way: The agar tubes are taken out from the bottle, wiped off, and inspected. The hemoglobin tube shows a change of appearance (due to the action of the trypsin) and a clearing up of the end part, becoming more or less transparent; the oil tube manifests a bluish appearance (the steapsin ferment splits the oil into fatty acids producing this color) at the end. The lengths of transparency in the hemoglobin tube and of bluish color in the oil tube are measured and stated in millimeters (Fig. 4). The starch tube is further examined by pushing out the agar column and dipping it into a weak iodine solution. The portion of the starch column remaining colorless indicates the part changed (by the amylopsin ferment) into sugar and is given in millimeter lengths.

Thus, the hemoglobin serves to gauge the trypsin, the olive oil the steapsin, and the starch the amylopsin ferments. As a thermostat I have recently used Freas' electric oven, which is very convenient indeed.

Characteristics of the Duodenal Contents.—They mostly consist of pancreatic juice, bile, and some duodenal secretion proper. The mixture looks golden yellow, is clear (transparent), viscid, and

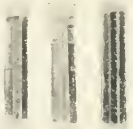

FIG. 2.—The agar tubes sealed with paraffin.

alkaline to litmus and methylorange (alkalinity = about 20), but rather acid to phenolphthalein.

* The agar tubes for testing the pancreatic ferments may be obtained at Eimer & Amend, 205 Third Ave., New York City.

(I have as yet never encountered duodenal contents that gave a reddish discoloration with phenolphthalein.)

The yellow color ordinarily changes after a few hours of standing, losing much of its brightness

Fig. 3.—The agar tubes have been put in the bottle containing a small amount of duodenal contents. The specimen is ready for the digestion test in the oven.

and becoming slightly greenish and also turbid. The fresh contents are free from any particular odor. After standing a few hours, however, they begin to manifest an unpleasant odor, which rapidly increases (due to decomposition or rather putrefaction through the influence of bacteria). They then present a fetid odor resembling feces.

I have made the observation that patients who take about three to four teaspoonfuls of glycerin daily furnish duodenal contents that do not decompose for two or three days. They retain their freshness and remain without any particular odor for that length of time. This fact seems to be due to some derivatives of glycerin being excreted with the bile and exerting this antizymotic influence. When glycerin is directly added to duodenal contents, it likewise preserves them from decomposition.

The observation that glycerin acts in the manner described can be utilized therapeutically for affections of the liver and mainly of the gall-bladder.

The Duodenal Contents in Normal Individuals.—In order to ascertain the condition of the duodenal contents in health, several apparently perfectly healthy persons were examined with regard to the state of their pancreatic secretion. They took the duodenal tube either at night before retiring, or between 4 and 5 A. M., with a glassful of water. They then slept, arose at 8 A. M., and called at my office at 9 A. M. in the fasting condition, when duodenal contents were obtained. I am greatly indebted to them for their willingness to be thus examined. In Table 6 are given their names and the result of the duodenal contents examination in the fasting condition.

The amount of ferments in normal individuals fluctuated as follows: Amylopsin, 4 to 8 mm.; steapsin, 2 to 5 mm.; trypsin, 0.5 to 5 mm.*

The average figures were: Amylopsin 6 mm., steapsin 3.5 mm., trypsin 2.8 mm.

The alkalinity, as determined by one-tenth standard solution of hydrochloric acid with methyl-orange as an indicator varied between 15 to 40. The rennet ferment was present in all.

B. Pathological.—During the last three years I have examined 170 patients with regard to their duodenal contents, making about 275 analyses of the pancreatic secretion. The examination took place either in the fasting condition of the patient or after tea and sugar or clear bouillon, ordinarily about one to one and a half hours after the ingestion of the latter into the stomach. The duodenal tube was introduced either the night previous or two or three hours preceding the examination. The contents were obtained first by aspiration, then being followed by syphonage. The quantitative examination of the amounts of the different ferments was determined by the agar tubes described above. The alkalinity was determined in 57 patients and averaged 22. Ordinarily it fluctuated between 10 and 30. One patient showed an alkalinity of 80, which was exceptional. As far as I can see there is no relation between gastric acidity and pancreatic alkalinity.

In looking over the results obtained by these examinations there exists a noticeable independence between the three different ferments with regard to quantity in the same individual—*i.e.* one ferment may be present in large amounts, while the other two may be present in small amounts or may be absent. The quantity of one ferment does not permit us to presume the amount of the two other ferments. It is, thus, necessary to test for each of the three ferments separately. This is accomplished in the most convenient way by means of the agar tubes.

The pancreatic secretion is subject—similar to the gastric juice—to functional anomalies or deviations from the normal. The juice may contain an overabundance of ferments or too small an amount of them. Again there may be hypersecretion or greatly diminished secretion. While in the gastric juice the functional activity is generally reckoned by the amount of hydrochloric acid present, there has as yet no definite substance of the pancreatic secretion been selected for this purpose. The trypsin ferment being the most important ingredient of the pancreatic juice, I would suggest to use it as a gauge for the functional activity of this gland. The following terms may then be advantageously used:

Table VI.—Examination of Duodenal Contents in Normal Persons

No.	Name	Date	Amylopsin, Mm.	Steapsin, Mm.	Trypsin, Mm.	Remarks
1	Miss E. Plate	III, 14, '15	8	6	4	Goldeo yellow, clear, alk. = 20.
2	Miss J. Todd	III, 2, '15	8	4	3	Goldeo yellow, clear, alk. = 15.
3	Dr. F. Gorham	III, 18, '15	4	5	3	Watery, greenish, alk.
		III, 18, '15	5	5	4	Bile stained.
4	Miss H. Lohr	III, 7, '15	8	2	0·5	Greenish, turbid.
5	Dr J. McCafferty	III, 31, '15	11	5	5	Goldeo yellow, clear, alk. = 45. In 10 minutes 14 c.c. rennet present.
6	Miss E. Schmz	IV, 3, '15	5	2	1	Goldeo yellow, slightly turbid at bottom. Slightly acid (=4 c.c. In 8 minutes, 2 c.c.
7	Miss M. Hartmann	IV, 3, '15	8	—	2	Golden yellow, watery, neutral. After water in 5 minutes, 20 c.c.
8	Miss A. Jansen	IV, 3, '15	15 (Erythrodextrin)	8	3	Golden yellow, somewhat turbid at bottom. Alkal. = 10. In 10 minutes, 2 c.c.

* The trypsin figure of 0.5 mm. in case 4 cannot be considered normal,—the secretion looked greenish and turbid,—nor that of 5 mm. in case 5,—as evidenced by the great amount of secretion (14cc. in 10 minutes), which is a great exception.

Eupancreatism = normal function; all three ferments present, trypsin showing the normal quantity (1 to 4 mm.).

Hyperpancreatism = increased activity; all three ferments present, trypsin existing in excess (above 4.0 mm.).

Hypopancreatism = diminished activity; the three ferments present, trypsin decreased (below 1 mm.).

Dyspancreatism = disturbed function; one or two of the three ferments are absent.

Heteropancreatism = varied function; the presence and amount of ferments showing no constancy, but variations every now and then.

In addition to these qualifications of the pancreatic juice which refer to its strength in ferment activity, we must discern the secretion as regards its quantity. There is then normal pancreatic secretion (euchylia), too much secretion or hyperchylia, and too little secretion or hypochylia pancreatica. Achylia pancreatica would mean there exists no pancreatic juice at all. Adolf Schmidt has used this term, but not exactly in the sense meant here. According to the terminology above stated, his cases would rather belong to the group: "dyspancreatism."

True pancreatic achylia—by this is not meant absence of pancreatic juice in the duodenum, due to the occlusion of the Wirsungian canal, for here secretion takes place but does not reach the intestine—does exist, but is very rare. It is encountered in the last stages of chronic pancreatitis and is, therefore, of grave significance.

The list of my cases being too large, even for publication in table form, I shall rather limit myself to a résumé of my collective cases, giving the more important items in greater detail.

The bulk of the cases consisted of patients with gastric and duodenal ulcers. The reason for this is that these patients were treated with duodenal alimentation, and their pancreatic secretion could thus be obtained at any time without any further trouble. There were 75 gastric and 24 duodenal ulcers.

The pancreatic function in the cases of gastric ulcer was as follows: Eupancreatism in 33 (44.5 per cent.); hyperpancreatism in 8 (10.5 per cent.); hypopancreatism in 27 (36 per cent.); dyspancreatism in 7 (9 per cent.).

In duodenal ulcer the following relation was found: Eupancreatism in 9 (37.5 per cent.); hyperpancreatism in 2 (8 per cent.); hypopancreatism in 9 (37.5 per cent.); dyspancreatism in 4 (17 per cent.).

We submit in the following table (7) the results of the analysis of pancreatic secretion in cases of achylia gastrica, chronic pancreatitis, cirrhosis of the liver, cholecystitis and cholelithiasis, and diabe-

Table VII.—The Duodenal Contents in Cases of Achylia Gastrica, Chronic Pancreatitis, Cirrhosis of the Liver, Cholecystitis and Cholelithiasis, and Diabetes Mellitus

No.	Name	Diagnosis	Stomach Contents	Date	Amylopsin	Steapsin	Trypsin	Remarks

tes mellitus, all conditions which deal intimately with the biliary and pancreatic functions.

There were six cases of achylia gastrica, among which one belonged to eupancreatism (16 per cent.) and five to dyspancreatism (84 per cent.). Among

Fig. 4. The agar tubes after having been subjected to the action of pancreatic juice. O, olive oil; H, hemoglobin; S, starch; the latter has been dipped into a weak solution of iodine.

six cases of chronic pancreatitis there was eupancreatism in two (33.5 per cent.), hyperpancreatism in one (16.5 per cent.), hypopancreatism in one (16.5 per cent.), and dyspancreatism in two (33.5 per cent.).

Seven cases of cirrhosis of the liver showed eupancreatism in three (43 per cent.), hyperpancreatism in one (14 per cent.), while in three there was dyspancreatism (43 per cent.).

In six cases of diabetes mellitus there was eupancreatism in four (66 per cent.), hyperpancreatism in one (17 per cent.), and dyspancreatism in one (17 per cent.). The table just reported fully corroborated the existence of the different pancreatic states described above.

As an instance of hyperpancreatism and pancreatic hyperchylia I would like to describe the following case:

Feb. 2, 1915. Sidney M., aged 29, salesman, complains mainly of looseness of the bowels and griping pains in the abdomen. He had diseases of childhood and slight gastrointestinal indigestion for the past few years. The acute condition began last June with intervals of improvement. At all times the stools have been more or less thin. Bowels move at least twice daily at all times, but may increase to 6-7 times. The pains were griping in character, about one minute. His appetite has always been good and taste normal. Has never complained of pyrosis, nausea, or vomiting. He never belches, or passes gas per rectum to any great extent. He has lost about seven pounds since last summer.

The physical examination revealed no abnormalities in the thoracic organs. The stomach was considerably dilated, the liver slightly enlarged. The gastric contents showed the presence of HCl and an acidity of 50.

The duodenal contents were examined on Feb. 8, 1915. Six c.c. were obtained in three minutes; golden yellow, clear, alkalinity = 25, rennet present, amylopsin 6 mm., steapsin 6 mm., trypsin 10 mm.

The duodenal contents were again examined on Feb. 22, 1915. Five c.c. were obtained in three minutes, golden yellow, mixed with mucus, alkalinity = 25, amylopsin 6 mm.; steapsin 5 mm.; trypsin 5 mm.

It is not improbable that the pancreatic hyperactivity in this case is the cause for the obstinate and persistent diarrhea.

Heteropancreatism is well illustrated by the following case:

Nov. 7, 1914. Miss Harriet P., 24 years old, was well until the age of 12, with the exception of diphtheria and measles, when she began to menstruate and suffer from dysmenorrhea. At 16 years she was curetted. She then began to be troubled with severe pains and burning sensations in the right iliac and kidney regions. This pain had been present even before the curettage, but not so intensely. Two months after the curettage the appendix was removed. The appendix contained pus and fecal concretions and the wound healed only with a great deal of suppuration. After the operation her symptoms of pain on the right side did not improve.

She had been constipated since her twelfth year, which continued, and she also now began to suffer from epigastric distress, which became always worse after eating and drinking. At times there was nausea. Appetite was always good, but she could not gain strength.

Finally in Oct. 1911, a gastroenterostomy was performed. At the operation narrowing of the pylorus was found, dilatation of the stomach and adhesion between gall bladder and site of removed appendix.

After this operation she felt better for a while, could eat better and picked up a little, but gradually the epigastric distress and nausea returned with sour eructation. Her legs became weak, so that she was unable to walk much in the last ten months. She is constipated and has mucus and at times bright blood in her stools.

Physical examination shows a [illegible] dilated stomach, and a right movable kidney (third degree).

Nov. 8, blood examination: hemoglobin 60 per cent. red blood cells 3,200,000; white blood cells 8,600. Gastric contents: HCl 20+; total acidity = 30; blood absent; microscopical examination negative. Stool: faintly positive to guaiac reaction.

Dec. 13, gastric contents: HCl = 0; total acidity = 40; no blood. The stomach washing in the morning always showed the presence of food particles, which stagnation was also confirmed by *x*-ray examination. The string test showed a blood stain localized in the stomach.

Nov. 12, the bead test revealed appearance of beads after 65 hours: fish bone, catgut, meat, a quarter fat, thymus, nuclei present.

The duodenal contents examined on Nov. 14 showed: amylopsin = 12 mm.; trypsin = 2 mm.; steapsin = one half mm. The duodenal contents: golden yellow, clear alkaline; amylopsin = 5 mm.; trypsin = 15 mm.; steapsin = 18 mm.

Dec. 30, the duodenal contents: yellow, neutral; amylopsin = 22 mm.; trypsin absent; steapsin = 3 mm.

Patient was kept for two weeks on duodenal feeding. This resulted in improving the motor functions of the stomach, the latter then emptying completely over night. The intestinal disturbance, flatulence and constipation, although likewise improved, by phenolphthalein agar and pancreon, still persisted.

The variable state of pancreatic function was here found in a neurotic lady, suffering from gastric ulcer with pylorospasm and slight ischochymia.

While in this instance the varied functional activity of the pancreas was produced by neurotic influences, it may occur by pathologic changes of the gland. The latter factor appears to have played a part in the following case, which I shall briefly sketch:

Feb. 20, 1915. T. L. R., aged 43, complains for the last ten months of distress in stomach and constipation. He vomits only after drinking a few glasses of beer. During the last 7—8 months he lost about 25 pounds. He never had syphilis.

The stomach is found to be dilated and the liver enlarged. In the stomach contents HCl is present with a total acidity of 45. The urine shows 2½ per cent. of glucose. The string test showed permeability of the pylorus and no blood on the string. Examination of the duodenal contents showed absence of steapsin and trypsin and presence of amylopsin (5mm).

A few days later, after rest and a proper diet, and after total abstinence of alcoholic beverages, the duodenal contents showed, alkalinity = 45, amylopsin = 15 mm., steapsin = 4 mm., trypsin = 3 mm. The urine was free from sugar and albumin. The liver was markedly less swollen and patient began to gain in weight.

It is fair to assume that the disturbed pancreatic function was caused by an inflammatory process of the entire gland, involving also the islands of Langerhans, as evidenced by the presence of sugar in the urine. The rational way of living produced a change for the better, so that the inflammation

subsided. The sugar then disappeared, and the pancreatic function returned to normal activity.

The insight into the workings of the pancreatic function appears to be of importance not only in disturbances of this gland and its neighboring organs, but in all diseased states of the entire organism.

The exact knowledge of the pancreatic activity will often assist in conjunction with other symptoms in making a diagnosis of a functional or organic disease of this gland. Moreover, it will always be helpful in constructing an appropriate diet for any given case, no matter of what affliction.

THE GIVING OF NAUHEIM BATHS IN THIS COUNTRY.*

BY SIMON BARUCH, M.D.,

NEW YORK.

THE value of water as a therapeutic agent in cardiac diseases consists in its great adaptability to cardiac capacity, as indicated by the pulse, respiration, and excretions; moreover, the action of water with or without chemical ingredients is so rapid that it can be equalled by only one drug, namely, anyl nitrite. While digitalis and other drugs have but one therapeutic function, water may be utilized for apparently opposite conditions, if applied upon a strict physiological rationale. For example, when the cardiac muscle is losing its power to overcome valvular defects it is dangerous to prescribe a bath of several minutes and of low temperature, because the peripheral resistance may overstrain the cardiac muscle. For this reason it requires more skill to apply water than drugs. On the other hand, water is superior in that its action may be withdrawn before serious damage is done, while a drug continues to act until eliminated. This advantage of hydriatric procedures is not sufficiently recognized. All hydriatric procedures depend for their therapeutic effect upon what is called reaction. In my work on hydrotherapy (published by Wm. Wood & Co.) this subject has been fully discussed. Suffice it to say here that I divide reaction into general and local reaction, not forgetting that both act simultaneously in most instances. I may say, en passant, however, that the Nauheim bath initiates a local reaction.

When we dash very cold water upon a fainting person, we get a purely reflex reaction; when we plunge a patient into water of the same temperature, we get first a reflex then a local and quickly a general reaction. In the customary Nauheim bath the water is not cold enough to arouse a decided reflex effect.

The long accepted Winternitz theory of reaction is based upon cold contracting the cutaneous vessels producing peripheral resistance and reddening of the skin, due to secondary dilatation of the vessels; this he calls *tonic reaction*. The reddening of the skin under warm applications he attributes to atonic reaction.

Tonic dilatation of a vessel is unphysiological; therefore the theory is fallacious. I have for many years taught a new theory of reaction based upon anatomical and physiological data, holding that the redness of the skin, during reaction following ordinary cold procedures is not due to contraction and subsequent dilatation of the cutaneous vessels. The capillaries which carry most of the cutaneous blood have no muscular coat, therefore cannot contract. Contraction of the cutaneous arterioles and arteries can only be produced by prolonged and intensely cold applications, which no intelligent hydrotherapeutist ever applies. In an article on "Fatality of Textbook Hydrotherapy" I pointed out the fatal fallacy of ice water baths. The Brand bath of fifteen minutes' duration at from 65° to 70° F. is the coldest bath administered by physicians. This would be fatal if friction did not stimulate reaction. Here is first a vasomotor action, which produces increased ventricular contraction—nerve or reflex reaction is aroused; at the same time the unstriped muscular fibers in the skin, together with the arrectores pilorum are contracted upon the abundant network of capillaries, which are packed into the pyramidal spaces, squeezing the blood out of them into the deeper vessels, so that the latter become more plethoric, instead, as Winternitz assumes, being contracted.

When the ventricle under vasomotor stimulation from cold drives the blood into the periphery, the previously depleted capillaries give way to the onrush and this effect is aided by what Bier calls the blood-sense, upon which, as you know, is based the Bier (suction) method in surgery. (See "Principles and Practice of Hydrotherapy" published by William Wood & Co., 3d Ed. p. 55.) After removal from the bath the skin presents a ruddy appearance, *because of the overfilling of the capillaries*, which are merely endothelial tubes, without muscular coats. I regard the smooth cutaneous muscular fibers as practically a muscular coat to the capillaries. I am sustained in this view by Tomsa, Sappey, Unna, and Haggquist. Quoting from my book p. 5: "Tomsa has clearly shown that when the arrectores pili contract they draw the skin from without inward, embracing in their action the terminal portion of the blood supply in the papillary body, and thus they empty the smallest blood-vessels in such manner as may best conduce to normal circulation. "There are many proofs, according to Unna, that the action of the arrectores muscles is not confined to the hair follicles, but that they are intimately involved in the movement of the blood and lymph." (This explains the vital import of the contractility of the skin when exerted upon the small blood-vessels contained in it.) "Inasmuch as the condition of the tension of the skin may thus be readily varied in the most direct manner by reason of the universal presence of the elastic fibers, and inasmuch as muscular coats are either absent in the vessels of the skin or are feebly developed, *these structures really perform the function of an inhibitory apparatus*, which distributes uniformly pressure and motion, and enables the oblique muscular fibers, which are embedded in the skin to regulate to a certain extent secretion and circulation, the movement of lymph, and consequently the nutrition."—(Unna.)

That this cutaneous muscular fiber is not under

*Discussion of Dr. John S. Thacher's paper in the Symposium of the Academy of Medicine, May 15, 1915.

vasomotor influence is not generally known, but it was proved in the Columbia University Physiological Laboratory, by Dr. Heinrich F. Wolf, under Prof. Opitz's direction.[1] Wolf placed his right arm in a plethysmograph, containing water at different

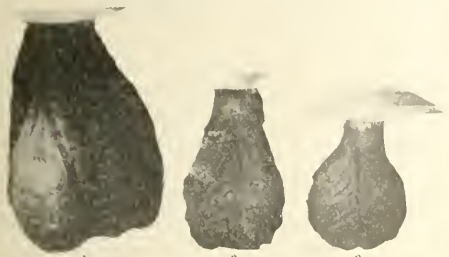

FIG. 1.

temperatures, and while the record was taken by Opitz inhaled nitrite of amyl. The inhalation enhanced the volume increase in his arm when the plethysmograph was filled with water at 35° C., but it failed to prevent the decided diminution of volume, resulting from exposure to water at 3° C. This experiment would indicate that while the arterial vessels are under vasomotor control, the capillary territory is probably under control of local nerves, which innervate the smooth muscular fibers of the skin. Indeed, Hasbrouck[2] had already affirmed the complete independence of the capillary circulation from the vasomotor system.

My theory of reaction after cold water is fully sustained also by Arthur Hirshfeld,[3] who at my suggestion in 1912 (as he mentions) subjected it to investigation in Prof. Brieger's Hydrotherapeutic Clinic, following my method of using the scrotum, in which the dartos presents the most sensitive smooth muscle fibers, open to attack by cold. I now show you his illustrations (Fig. 1):

1. Shows the scrotum after an electric-light bath, relaxed and enlarged.

2. After half an hour application of cold water, flowing through a coil, decidedly shrunk, with rugæ.

3. After a milder application of cold water, less rugous but contracted. (*Zeitschrift f. exp. Path. u. Therap.* 17 Band.)

Rationale of the Nauheim Bath.

The application of this anatomical and physiological reaction theory to the Nauheim bath removes much of the existing obscurity of its rationale. I claim that the temperature of the Nauheim bath, the lowest of which appears to be 28° C. (82° F), a rarely used minimum, and the highest, 36° C. (96° F.) or an average of 89° F., is insufficient to account for the reaction, because it is only removed 3° F. from the natural temperature of the skin, which is 92°. According to my hydrotherapeutic law, the greater the difference of temperature between water and skin, the more intense is the therapeutic effect. A water temperature of 89° F. would therefore be almost neutral, unless very much prolonged. In the early nineties[4] I showed that a tubbing at 80° F. restored a temporarily tobacco-weakened pulse from a dicrotic to a normal condition. This effect no Nauheim bath could ever surpass. My view that pure temperature effect may produce better results, or at least as good, as the Nauheim bath, was published many years before it was confirmed by Ottfried Müller, but as before mentioned, it would be dangerous to subject an organically failing heart to even a temperature of 80°. And right here is demonstrated the clinical acumen of Beneke and his successor, the elder Schott and their followers.

Our Nauheim colleagues habitually resort to temperatures decidedly above 80° F. with results that have made their resort famous. What then is the reason for improvement of the failing heart after CO_2 baths of almost indifferent temperatures? I have never been satisfied with their rationale, because it appeared occult. Actual observation at the bedside has convinced me that:

1. The CO_2 endows water of nearly neutral temperatures with an action similar to that of water at a lower temperature so far as its local effect goes; it, too, produces contraction of the smooth cutaneous muscular fibers, which presses the blood out of the capillary network into the larger vessels, inducing peripheral resistance without, however, the distinct vasomotor action of colder water. This action is evanescent.

2. CO_2 is absorbed by the skin, is carried to the respiratory center, with the result that the right heart is unloaded and stasis is removed, which is perhaps the most menacing element in failing of the heart. These are proven physiological facts.

3. The CO_2 circulating in the blood acts directly upon the heart muscle, stimulates the ventricle to vigorous contraction which is manifested in the pulse rate, tension, and amplitude. Those who may be incredulous upon this point need only to be reminded that in carbon-dioxide poisoning the heart stops in systole. Is it then not logical to assume a milder effect from a smaller dose of this poison, a method adopted in laboratory experiments on drug action? That CO_2 is absorbed actively from water, especially when containing sodium chloride, and passes through the skin has been fully demonstrated by H. Winternitz, whom I visited at von Mering's clinic, for the purpose of obtaining personal verification of this and other valuable findings, on the physiology of the baths. I found that they were obtained under every precaution against fallacy. The discovery by E. B. Meigs[5] (*Journal of Exper. Physiology*, 1912, p. 497) that contraction of smooth muscular fiber lasts longer than that of the striped explains the prolongation of the effect of a CO_2 bath upon the tone of the cutaneous fibers, which thus present at first a feeble barrier of resistance to the blood driven against it,

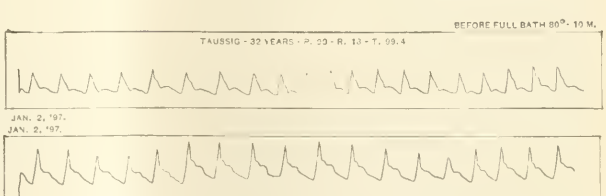

FIG. 2.

by the increased ventricular action. The capillary blood supply is enormously increased and the redness is maintained by the friction of the gas bubbles and the protection afforded by them against the colder water above. That the local effect of the CO_2

bath is the same as after a moderately intense cold application, like that shown in Fig. 3, was clearly demonstrated by photographs I had taken in the Nauheim bathhouse by courtesy of Geheimrat Eser, and with the assistance of Dr. Albert J. Wittson of New York. I showed these photographs to Professor Groedel who asked me to permit him to present them and my new rationale of the action of the CO_2 bath to the forthcoming Congress in Karlsbad. In the transactions of that Congress which Dr. Thacher was good enough to lend me, the presentation of my photographs is mentioned by Dr. Groedel, who drew attention to "the folding of the skin, which is clearly shown" as the result of the strong CO_2 bath. Dr. Groedel said that he did not quite agree with my new rationale, because "one may ask himself if this action upon the sensitive scrotum may be repeated upon the general cutaneous surface?" I do not claim this, but we may logically deduce analagous action modified by a less sensitive and abundant muscle fiber supply in the latter. Since hitherto all the experiments to develop the behavior of smooth muscular fiber under varying conditions have been made upon animals (Schultze on the bladder muscle of the cat cited in my book), I concluded to use the dartos of the human subject. Another doubt in Groedel's mind appears to be that " in a bath of 32° C. (89° F.) it may after all be a thermic stimulant only." This view is contradicted by the absolutely indifferent effect upon the scrotum of ordinary water in my Nauheim photograph which he was showing. The comparative merits of our respective rationales of the CO_2 bath is evident from the following résumé. Groedel writes "CO_2 exerts a *peculiar* action which irritates *peculiarly* the cutaneous nerves, exciting reflex action and, giving the heart increased energy, which is enhanced by the rapidly changing warmth and cold sensation which also produces *peculiar excitation*." I show you by actual demonstration and well known anatomical and physiological principles a logical rationale. Groedel rests upon a belief in the *peculiar* qualities of CO_2. The fact is that our Nauheim colleagues merit our utmost confidence in their clinical statements but their explanations of the action of CO_2 baths have never satisfied me, because of their obscurity.

Hydrotherapy of the failing heart is more flexible than drug therapy, though the latter is perhaps more rational than in any other disease, not depending on a specific germ. The water treatment may be graded and adapted in heart disease as it is in other maladies. If the case be urgent I would begin with the object of relieving cardiac action by a full bath of 95°, with four pounds of salt and one-half pound of chloride of calcium to forty gallons of water, for six to eight minutes. This saline ingredient counteracts by slight irritation of the cutaneous nerves any deleterious relaxation that may ensue from such a bath. Later cardiac exercise is produced by lowering the temperature of the water from time to time, the skin becomes inured and may be brought to bear a temperature of 90° or less with comfort. As the tone of the cutaneous structures rises and the heart becomes more capable of adapting itself to this slight peripheral resistance, CO_2 is added to the bath, in accordance with the change in the quality of the pulse.

In this way, guided by the principles which I have enunciated, the varying phases of cardiac insufficiency may be successfully met. While the artificial Nauheim bath is doubtless of great benefit, when judiciously executed upon these principles, there is no doubt that resorts like Saratoga Springs in this country, and Nauheim, Kissingen, or Marienbad, abroad, present definite advantages in addition to the natural CO_2 bath, by reason of the patient's removal from unfavorable environment to restful

Fig. 3.—Coesa Spring showing the column of the CO_2 gas.

surroundings, under the care of colleagues, who have accumulated large experience in these resorts.

Some years ago I wrote in Hare's "American System of Therapeutics": "It is more important for the doctor who sends a patient to a health resort to know the mental composition of his colleagues at the springs than the chemical composition of the water of those springs."

My advice to the Reservation Commission of the State, which owns the springs, to encourage the building of hotels away from traffic, will doubtless be adopted. It has been a patriotic labor of love to have been active in counseling the Saratoga Springs Reservation Commission in their successful conversion of this spa into a modern health resort. Their qualities are those of Kissingen and Marienbad, and as, in these resorts, by addition of the necessary proportion of chloride of sodium and calcium, the perfect Nauheim bath may be obtained, since the mineral ingredients of the latter play a minor rôle. They are now the peer of any spa furnishing CO_2 waters in the world.

That this is not an unwarranted statement and that an example for emulation by owners of other valuable springs in this country may be furnished, a brief history of the regeneration of Saratoga Springs may serve a good purpose. Several years after the ruinous commercial exploitation of the Springs had led to their condemnation and purchase by the State of New York, I was invited to address the Saratoga County Medical Society on "Hydrotherapy." I utilized the opportunity to point out the deplorable state of balneology in this country and presented suggestions for its removal. Taking Saratoga as an example, the need of constructing beautiful parks, building modern bathhouses, improving the neglected springs which was already progressing, providing hotels in quiet localities, etc., were urged. Without my knowledge the State Reservation Commission which had charge of the entire renovation, also other officials, had been invited. Two months later, while in attendance at the London Congress, I received a cable from the Commission confirming a request previously made by General Tracy, the city member, to inspect in behalf of the State of New York the most noted spas in Europe. Entering upon the task as a labor of love and patriotism, I studied Bath and Harrowgate, Vichy, Baden-Baden, Wiesbaden, Nauheim, Kissingen, Karlsbad, Marienbad, Franzensbad, most of which I had previously visited. Meeting at Kissingen the brilliant head of the Royal Laboratory, Dr. Paul Haertl, I engaged his services tentatively, not having authority to do so, to come to Saratoga. The Commission confirming my arrangement, Dr. Haertl came over and made a complete survey of the situation, pointing out many flagrant defects in the conduits of the waters, their delivery, etc., and expressing astonishment at the abundance and large percentage of CO_2 waters there. My own recommendations in an extensive report had included the leaving of all medical matters to the local Medical Society, the listing at each spring of all reputable physicians, the absence of a medical director in order that physicians may have free scope, the establishment of properly equipped bathhouses, of first and second class, as is done abroad, providing modern facilities for hydrotherapy, electrotherapy, and mechanotherapy, good hotel accommodation, etc. Later the Commission sent Prof. C. G. Anthony of Schenectady abroad to study the engineering problems involved at the large spas. He made a valuable and instructive report. Dr. Albert Warren Ferris, formerly State Commissioner of Lunacy, was appointed supervising director to carry these ideas into execution, to present the merits of this valuable State property to legislative committees, and to familiarize the medical profession with the therapeutic advantages of this only State-owned health resort, whose chemical analyses are made by the State chemist.

No resort in the world now excels Saratoga Springs in fulfilling the demands of Dr. Thacher's able paper.

Note—Since the above was written, the author has spent four days at Saratoga Springs for the purpose of repeating Nauheim photographic observations referred to above. Through the courtesy of Dr. Ferris, supervising director, and Herbert Ant, chief of the chemical laboratory, photographs were taken before and after simple water baths and baths in the waters of Hathorn No. 1 (138 per cent. saturation) and High Rock Spring (122 per cent.) The results were almost exactly the same as at the Nauheim bathhouse. Graphic pulse tracings were also taken in connection with the photographs and blood pressure observations were made for me by Dr. A. Sherman Downs of Saratoga Springs at the same time. All these are being prepared for publication. They demonstrate conclusively that the waters of these springs are similar to those of Nauheim, Marienbad and Kissingen in physiological action and therefore in therapeutic effects in cardiac and nervous diseases.

DOCTORS MARCQUIS AND BOUDEWYNS OF ANTWERP

AND SOME OF THEIR INTERESTS DURING AND AFTER THE FORTY AND THIRTY YEARS' WARS.

By JOHN BETHUNE STEIN, M.D.,

NEW YORK.

In 1571, four years after the commencement of the forty years' war in the Netherlands, the Duke of Alva wrote his master, Philip II. of Spain, from Belgium, that the people of that country had still the same character which had been described by Julius Cæsar.[1] At the outbreak of this war Antwerp was the commercial capital of the world and one of the most beautiful cities in Europe, inclosing within its walls some of the most splendid edifices in Christendom.[1]

By an act of May 6, 1598, Philip II. had given the sovereignty of Belgium to the Archdukes Albert and Isabella. Belgium, still in the throes of war, had lost much of its ancient splendor. Antwerp and all the cities on the coast were then or had been blockaded by the Holland fleet and remained for a long time closed to commerce, many cities were depopulated, many industries had been destroyed or transported to England or Holland, and the country was covered with ruins. The Archdukes, in spite of the continuation of the forty years' war, did much to efface these disasters. In 1609 the war ended, and,

as Motley says, "there was a vast lull between two mighty storms. The forty years' war was in the past, the thirty years' war in the not far distant future."[1]

The genius of Belgium which had been dormant

Fig. 1. Lazarus Marcquis. The Friend and Physician of Peter Paul Rubens.

for forty years revived to a second renaissance of science, letters and art, and in 1613 was begun the construction of the canal from Ghent via Bruges to the sea.[2] This revival was due in part to the opening of commerce between Antwerp and foreign countries and to printing by the efforts of the Plantins and Moretuses at Antwerp, but principally to the fact that men prominent in every walk of life were attracted to Antwerp and resided there because it was the home of the great diplomat, statesman and Flemish painter, Peter Paul Rubens. It was to the house of Rubens that savants came to relate their discoveries and exchange opinions. These receptions which were held every evening at Rubens' house were the forerunners of and probably there was first considered the formation of the several learned societies which were later organized in Antwerp.[3]

At this time the laws governing the practice of medicine were observed but little. Any tyro could practise without being prosecuted. Pharmacists were not required to pass an examination to practise, their establishments were not inspected, and they dispensed drugs without a physician's prescription. The midwives were ignorant and surgeons went through only the form of an examination.[3] An early ordinance of Charles V.[4] reading as follows had apparently passed into oblivion:

"Charles, by the grace of God, Roman Emperor, Ever Promoter of the Empire, King of Germany, Castile, Leon, Aragon, Navarre, Naples, Sicily, Majorca, Sardinia, the Islands of India, and the vast lands beyond the seas; Archduke of Austria, Duke of Burgundy, Lorraine, Brabant, Limburg, Luxemburg, Gelderland; Count of Flanders, Artois, Burgundy, Hainaut, Holland, Zeeland, Namur, Zutphen; Count Palatine, Prince of Swabia, Marquis of the Holy Empire, Lord of Friesland, Salins, Malines, of the City, Cities, and Land of Utrecht, of Overyssel, Ruler of Asia and Africa.

To all those who shall see this letter: Greetings.

It has come to our knowledge that within this our city of Brussels many men and women, the greater number of whom cannot read or write Latin, German, or Walloon, are engaged in the practice of medicine, which is beyond their sense and knowledge, because of which much harm is done daily to the sick and the people of the said city; because the aforesaid masters and mistresses have no experience and cannot name the persons from whom or where they have obtained their knowledge and experience to practise medicine, and because they have written prescriptions for patients who were critically ill, and have often caused serious illness and even death by the administration of their remedies, and because the pharmacists had to correct their prescriptions.

Therefore we have foreseen and have taken precautions to protect the inhabitants of our cities from the dangers threatening their welfare as far as it lies within our knowledge and power.

For this reason is this letter written.

Henceforward no one, no matter whom, shall be permitted to take the title of doctor of medicine or doctress of medicine or give or cause to be given secretly or openly any laxative or emetic or theriacal, or any other medicines which are not compounded and prescribed according to medical rules with the approval of either a master or doctor of medicine; and no one shall give simple or compounded animal, vegetable, or mineral poisons to patients except after the latter have consulted with their own licensed doctors who either have graduated from an approved university or have been examined by the doctors of medicine at the University of Louvain or by those doctors of medicine practising in our city of Brussels. The aforesaid doctors must be paid an adequate fee for this examination, and if the applicant is found capable he is to be given a certificate to practise. Any one found acting contrary to this order shall be fined for each offence 20 guldens (Carolus), which shall be paid to our profit.

We also order, under the same penalty, that the pharmacists of our cities will not recognize or accept the prescriptions from so-called doctors or doctresses of medicine who have not been approved or examined as ordered, and that the pharmacists shall not sell them any medicines, not even laxatives or emetics or other simple or compound medicines to be given away or sold again.

And it is further ordered that two or three doctors practising in our city, appointed by us The Law, shall act as a committee and visit together three times yearly at four months' intervals, all the pharmacists of the aforesaid city with one or two pharmacists, for which The Law shall pay them a reasonable salary. Together under oath they shall make their visits virtuously and

Fig. 2. Michel Boudewyns.

reverently, and if they find that the dry, liquid, or other simple or compound medicines are not good, have spoiled, or are ineffective, the pharmacist shall be obliged to throw them into the street in the presence of the aforesaid doctors, and they shall use only those which are good and effective as judged by these doctors.

The officials of the law in the aforesaid city shall compel the pharmacists to accept this visit of the committee of doctors and any corrections which may be made by them.

The pharmacists shall be compelled to make their compounded medicines from simple drugs which they shall have obtained from a pharmacist who sells non-compounded drugs and whose establishment is also subject to visitation by the doctors.

No one shall establish a pharmacy other than the pharmacist who has learned his trade from a reputable pharmacist.

No pharmacist of this city shall be allowed to make Theriacam Andromachi, Magnam Theriacam Galeni, and Mithridatium except those who weigh carefully all the ingredients in order in the presence of the committee of doctors, so that no mistake may be made.

All weights and measures of all the pharmacists shall be of the same standard.

All pharmacists must have the drugs necessary to conduct properly their business and shall be compelled to show their books relating to their pharmaceutical supplies.

And further the act of medicine and surgery shall be practised according to the instructions we shall make.

Therefore we invite and recommend our cherished and loyal Chancellor, the people of our Council of Brabant, the Magistrate, the Mayor, the Sheriff, the Court of our aforesaid city of Brussels, and all other interested officials whom it may concern, that they observe and cause to be observed this our command and execute the same and prosecute the violators of this law and inflict the aforesaid penalty.

We recommend that the Magistrate of Brussels and the Governor constantly cry out and announce this law to the aforesaid officers of the law in the place where publications and outcryings are made, with the object that no one shall pretend to be ignorant of the same.

To this we have fixed our seal, given in our aforesaid City of Brussels the eighth day of October in the year of Our Lord 1540, and of our Empire the twenty-first, and of our Kingdom of Castile and other Kingdoms the twenty-fifth.

Signed by the Emperor in his council and undersigned by L. de Soete.

Drawn from The Book of Privileges of the City of Brussels named the "Carolyne," in which the aforesaid statute stands registered.

Foliis. 1. CXIXV. fo. 1. CXX, fo. V, which is found to be correct and undersigned by me the Clerk of the Court of the City of Brussels.

I. DE CONDÉ."

But in the early part of the seventeenth century this ordinance was not enforced, and in order to raise the standard of medicine in Antwerp the better element of the medical profession met and selected Lazarus Marcquis and Godfrey Vereycken to consult with the magistrate regarding the establishment of a medical college.[1]

Lazarus Marcquis, the friend and physician of Rubens, was born in 1571. Of his early life nothing is known, but his writings show he possessed considerable knowledge of history and philosophy, and of the Flemish, French, Spanish, Latin, and Greek languages, and it was in 1599 that he received the M.D. degree and began the practise of his profession.[1]

There was some opposition to the establishing of a medical college at Antwerp, but Marcquis and Vereycken convinced the magistrate of the importance of such an institution, their efforts being aided by the timely bequest of a Dr. Jean Ferreulx of his valuable medical library to the future college. Finally on April 28, 1620, the establishment of the Collegium Medicum of Antwerp was decreed. The first so-called "protector" of the college was Henry van Etter, who was succeeded in turn by Paul van Liere, Henry van Etter, Jr., and Jacques Roelants. The institution did not prosper under these "protectors," and the magistrate, after repeated requests of the physicians of the city, was compelled to reestablish it by a decree of September 12, 1624, placing at its head the mayor of Antwerp, Gregory Martens, an astute and enterprising man, under whose management the institution began to grow.

The directorate of the college consisting of seven physicians elected by their colleagues was given extensive power. They visced the diplomas of recent graduates; inspected the establishments of pharmacists; presided at the examination of surgeons, pharmacists, and midwives; designated one of their number to give a course in anatomy and surgery at the School of Surgery; saw that the poor of the city were given free medical treatment; and exercised judiciary powers which enabled them to act as a disciplinary board, and punish those who were practising illegally.[2]

Marcquis was interested not only in the medico-social uplift of Antwerp but also in the study of epidemic diseases especially the plague.

In 1605 the great epidemic of the plague was raging in Antwerp and here many physicians came to study this disease, among others a young Belgian who, after having received his M.D. degree at Louvain in 1599, had spent five years studying in Switzerland, Italy, France, and England, and was now on the way to his home in Brussels. This man, who was to become a pioneer in medical science, was Jean Baptiste van Helmont, in whose future work is found the beginning of chemical physiology.[3]

The almost uninterrupted warfare in Belgium, the ignorance or non-observance of hygienic laws, the commercial intercourse with foreign lands, made the country and practically Antwerp an easy prey to the plague. Epidemics were so frequent in the latter part of the sixteenth and first half of the seventeenth century, that the civic authorities at Antwerp issued almost yearly official instructions for avoiding this disease.[3]

Marcquis was selected by his colleagues at Antwerp to write a work upon the plague. This book, published in 1624,[6] was the following year translated into French and published at Lille. Eight years later an enlarged edition was published at Antwerp consisting of sixty-two pages, entitled "Brief Instructions by the Doctors of Antwerp for Avoiding the Plague, Enlarged and More Accurate, Explaining the Causes of the Disease, the Markings on the Dead Bodies, the Diagnosis, Prognosis, and Cure, and Containing also the Instructions of the Magistrate for Combating the Plague; Which Advises also How the Houses, Furniture, and Clothes Should Be Cleansed and How Confessors and Doctors Who Visit Infected Patients Should Protect Themselves."[7] In 1634, and again in 1636, editions of his "Complete Treatise on the Plague, etc.," consisting of 218 pages, appeared at Antwerp.[5]

Marcquis defines the plague as a "contagious, loathsome, speedy illness, killing many people, which sprouts out of mysterious poisons and rotten causes," and he describes the causes "as abstractions of the wrath of heaven in the air, soil, water, and human body," each cause producing in a particular place in the body a characteristic form of the disease. He says that "without a knowledge of the causes of the disease there can be no treatment," and of the symptoms "they vary with the nature of the epidemic." * * * "We have observed that death occurs without fever. This is caused by the infection of the air, which is inhaled, then absorbed by the heart, whereupon the spiritus vitalis is quickly destroyed before any buboes appear."

Marcquis did not approve of the burning of sub-

stances emitting offensive odors, such as leather, feathers, etc., to protect oneself from the plague; he declares that "a bad odor makes the spiritus vitalis ill, and a good odor makes the same strong." He blames the civic authorities for "not discerning what a harmful and deadly mistake it is to hire with the intent of saving money unlearned idiots (sic) and surgeons to treat this disease, because it requires those who have the keenest minds—the cleverest doctors and best surgeons."

According to Marcquis, the means of avoiding the plague are spiritual, political, and medical. The spiritual consists in reconciling oneself with God. The political is the control of the public hygiene by the regularly constituted authorities whose duties are to see that the streets and houses are clean, that no animals, such as pigs, pigeons, etc., are raised in the city, that frequent gatherings of the people and kermesses do not occur, that the sale of unripe fruit is prevented, that large fires are kindled and cannon fired several times, morning and evening, to cleanse the infected air, that those who die of the plague are buried deeply, that those who have contracted the disease are quarantined and treated by competent physicians, and that all foreigners and all parts of the country where the plague has appeared are carefully watched. The medical means of preventing the plague, are avoiding all kinds of excesses, keeping sober and clean; having good ventilation, taking from time to time a light laxative, keeping oneself in good health, and consulting at once one's medical advisor if an epidemic of the plague does occur.

He disagreed with many of his time who thought that powdered frogs, spiders, etc., were preventatives, but he did acknowledge the value of the lapis bezoardicus and precious stones, such as the hyacinth and the emerald.

He was opposed to bleeding the patient and to the administration of purgatives because "the disease is of a malignant nature," and advised great care in the treatment of each symptom, recommending to physicians the advice of Hippocrates, "quo natura vergit eo dirigenda curatio."

The work treats also of other diseases which occurred epidemically in Antwerp, such as miliary fever, ophthalmia, erysipelas of the face, and angina. Among other remedies he used sulphuric acid in treating the angina, and when it resisted all treatment he advised tracheotomy, an operation he did not consider dangerous.

Marcquis died December 20, 1647, the year preceding the peace of Westphalia, which terminated the thirty years war, and he was buried in the Church of the Dominicans at Antwerp.

Michel Boudewyns, Ph.D. (Louvain) M.D. (?), a native of Antwerp, and brother-in-law of Lazarus Marcquis, after studying philosophy and theology at the University of Louvain, with the intention of entering the church, decided to study medicine. He attended the courses in medicine at Louvain for three years, and then visited some of the other universities of Europe, probably receiving his M.D. degree at Paris in 1642.[9]

The marquisate of the Holy Roman Empire did not possess a pharmacopœia.[9] The dispensatory of Valerius Cordus,[10] which appeared in 1535, was the classic work for pharmacists throughout Europe. This work in Latin had been revised by Pierre Coudenberg of Antwerp, a pharmacist and friend of Christopher Plantin, and printed by Plantin at Antwerp in 1567. Coudenberg's French translation of it appeared at Lyons in 1575, and a Dutch translation of it appeared at Amsterdam in 1662. Two other Latin editions of this Cordus-Coudenberg work, with additions by other writers appeared at Leyden in 1627 and 1652 respectively.[11, 12] The revised dispensatory of Valerius Cordus by Coudenberg was still in use, but not up to date.

Under the auspices of the Medical College of Antwerp, Boudewyns edited the "Pharmacia Galeno-Chymica, etc.," [13] which the magistrate of Antwerp declared by an ordinance of September 27, 1660, to be the official "Codex" or pharmacopœia of this city. This ordinance annulled a decision of June 6, 1659, directing the pharmacists to follow the revised dispensatory of Valerius Cordus by Coudenberg for the preparation of their drugs.[9]

Of the practice of pharmacy in Antwerp at this period Boudewyns says in his "Practical and Satisfactory Treatise for the Sick":[14] "Here in the city of Antwerp learned and unlearned are permitted to start, hold, and keep an apothecary shop without any proof of being fitted for it. There is not a trade so mean, not even the carpenter's, glazier's or cobbler's, but that it must be overseen by the heads of the trade, and must serve well the people who pay money to those engaged in it. Those engaged in these trades must be examined by those over them and give satisfaction to the deans of the trade. The apprentices must serve a certain number of years learning their trade and must prove themselves competent to carry it out. It is but a stupid thing to ruin an old shoe; whereas, in the art of pharmacy, which is a matter of life and death for the people, there are many who, believing and judging themselves qualified to act as pharmacists in spite of their inability to write their own names, are permitted to hire a young man to read prescriptions to them."

Boudewyns in his work,[15] published in 1668, asks and answers seventy-five moral and theological questions, among which are the following:

Is medicine a useful art? [The author's proofs and affirmative answer fill six printed pages.]

May the physician wish and pray God that he may have many patients? Yes, but not to the disadvantage of others.

Can he have recourse to superstitions and witchcraft? No.

Can he make use of astrology? He may study the influence of the stars upon man.

Can he heal by magic a disease which is produced by magic? No.

Can one use human blood, flesh, fat, and bones in treating disease? Yes.

Can one prescribe amulets, collyria, etc.? Yes, but without superstitious practises.

Can one have recourse to charms, the pronouncing of sentences and words? No.

Can one treat the energumen and possessed? Their bodily infirmities only.

Is it lawful to use philters and drafts to excite love or hate? No.

Can the physician for his prognosis make use of chiromancy, metoposcopy, physiognomy, aeromancy, and dreams? One can have recourse lawfully to these insomuch as these sciences are related to medicine.

May chemistry be used in medicine? Without doubt; but alchemy cannot be used lawfully by the Christian physician.

Can one advise the use of preventives for drunkenness and venereal diseases? This practise is permitted in many cases without accusing the physician of favoring the debauch.

Can the physician order the patient to drink wine and get drunk? If it is necessary for a cure it is permitted.

Can he prescribe aphrodisiacs? One can use them, but not abuse them.

Is it lawful to prevent the generation of the seed or

destroy the seed already formed? Each one can debilitate the prolific ability by work or abstinence, never by drugs, and the seed once formed must not be in any manner corrupted.

Can the physician advise pollution in order to heal a disease? [The author proves by the unanimous testimony of physicians and theologians that this is unlawful.]

Can a physician look at and touch the genitals? Without doubt, if the nature of the disease requires.

Can he cut the hymen for the sake of health? Yes.

Can he advise marriage for the sake of health? Certainly.

Can he prevent conception? Not at all.

Is he allowed to perform the operation of castration? In some cases only.

Can the physician order one of a married couple to refuse the conjugal duty to the other? He is obliged to do so in some cases.

Is it at times lawful to cause an abortion? The physician can never do it directly. However in case of disease it is allowable to employ any means to save the pregnant woman.

May the physician take charge of desperate and incurable diseases? There exists no disease so desperate that the physician cannot lend his ministration to it.

Can he prolong indefinitely a disease and use only doubtful remedies? Unless an affection more grave is imminent it is neither lawful to prolong the disease nor to use doubtful remedies when there are sure ones.

Can one cure a disease by producing another? The duty of the practitioner obliges him to produce often a light affection in order to extirpate a graver one.

Can he omit to employ the necessary remedies under pretext that in case of their not succeeding his reputation would suffer? Those who act thus are culpable and unworthy the medical profession.

Can he use venoms, and how? Yes; as a remedy.

Is it lawful to use emetics and purgatives, to bleed, mutilate, burn, and cut the body. Yes. [These questions are answered from a theological point of view.]

Is it lawful to accelerate death in order to deliver from suffering a patient who is despaired of? All Christian physicians will abstain from it.

Does the physician owe the same care to all his patients? Yes.

Is it lawful to dissect the human body? It is not only lawful but is even necessary at times to open cadavers.

Is the physician obliged to give his services to heretics and persons afflicted with contagious diseases? He is not obliged to do so in every case. [Boudewyns argues that it is the duty of the Catholic physician to devote himself chiefly to those of his own religion, but he can assist heretics; and the physician who treats those suffering from a contagious disease not only exposes himself but his other patients as well to this disease. The author asserts the necessity of having special physicians hired by the city to treat the plague.]

Is it the duty of the physician to see that the dying are given the help of religion? It is the duty of the Catholic physician.

Can he suppress or deny the virtues of remedies when they are demanded of him? Sometimes he is obliged to do so in the interests of the patient.

Is he compelled, when demanded, to state that death is imminent? He must do it with discretion.

When the physician is questioned regarding the gravity of a wound or disease, is he compelled to speak the truth? The physician, on being required to do so by the judge, is obliged to tell the whole truth.

Is it lawful for the physician to reveal diseases of a secret nature when he is asked? The physician can make them known only under grave and extremely rare circumstances.

Can the physician receive honoraria for his cures? Yes.

Must he give gratuitous treatment to the poor? Without doubt.

Can he before undertaking to cure a disease stipulate his fee? The physician can demand a reasonable fee.

Can a physician exact a higher fee for a remedy composed or invented by himself from the rich than from the poor? Without any doubt.

Is it permissible for a physician to supplant his colleague in a case? [The proof that it is unlawful occupies four pages of Boudewyns' book.]

Is a prince or magistrate compelled to admit the art of healing into his domain? It is a duty in the interest of the citizens.

Is medicine according to one's conscience a lawful science? Certainly.

Can any one practise medicine conscientiously? Only those who have given some guarantee of their capacity can practise this art.

Is it the duty of the magistrate to see that there are good physicians, pharmacists, surgeons, and obstetricians? Yes.

Is it lawful to invoke the saints regarding diseases? Yes.

Must the patient permit the inspection of all parts of his body? Without doubt.

Can those who are impotent be married? No. [The author cites at length the different kinds of impotence.]

Is fasting obligatory for pregnant women and those who are nursing children? They are not obliged to fast.

Are those having atresia of the vulva compelled to submit to an operation? Without doubt, if marriage is to be valid.

When it is impossible to deliver a woman in a natural way, can she or must she submit to cesarean section in order that the child be baptized? If there is some hope of success the mother can permit the operation; she is not obliged to do so in all cases.

Is it obligatory to baptize all monsters and abortions? No.

The author then takes up the subject of teratology, discussing the existence of satyrs, pygmies, centaurs, hermaphrodites, succubæ, incubi, and sirens, and after asking if they should be baptized, proves that most of them are fabulous beings.

He discusses the hygiene of marriage, and whether or not the use of chocolate, wine, milk, and tobacco break a fast, and whether or not a certain order of monks must refrain from eating meat.

As indicating the intolerant religious spirit of this time he declares that the magistrate cannot admit Jewish physicians to practise medicine, and after stating that a mother must nurse her infant when her health permits it, he terminates the work by discussing the obligations of patients to pay their physicians.

Boudewyns served as secretary, president, and professor of anatomy and surgery at the Medical College of Antwerp, and was also city physician and physician to the Hospital of St. Elizabeth. He died October 29, 1681, and was buried in the Abbey Church of St. Michel at Antwerp.

A NEW GAS-OXYGEN-ETHER APPARATUS; DESCRIPTION AND USE OF THE INSTRUMENT.

By H. CLIFTON LUKE, M.D.,

NEW YORK.

ANESTHETIST TO ST. LUKE'S HOSPITAL

For the safe, intelligent, and satisfactory administration of nitrous oxide in general surgery an efficient and practical apparatus of comparative simple design is of first importance, and the writer believes that the following requirements should be met in such an instrument:

1. Provision for the even and continuous delivery of nitrous oxide and oxygen by the use of reducing valves.

2. An unchangeable and sufficiently accurate device from a clinical standpoint for separately measuring these gases.

3. Independent valve controls for each gas.

4. A system of rebreathing and ventilation which without waste or excessive accumulation of carbon dioxide will insure a fairly even mixture of the gases in the rebreathing bag at all times.

5. A reliable ether device which has independent valve control.

6. Four yokes to accommodate two gas and two oxygen cylinders, the extra one of each serving as a reserve supply.

7. The instrument should be obtainable in portable form; substantially built with as little glass and other fragile parts as possible. With these ideas as a guide, the writer has planned and completed the apparatus here described.

Description of Apparatus (See Fig. 1).—A graduated ether reservoir of about one ounce capacity is seen above and in the center. This is controlled by a pin valve (1) which allows the ether to pass drop by drop through the sight feed (2), whence it falls into the vaporizing chamber (3), through which a stream of all the used gases are made to pass. A small opening closed with a screw cap (4) is used for filling the ether cup, while a pet-cock (5) in the dependent part is used to empty it. At the lower part of the instrument are four yokes; two on the right (6) to accommodate two 100-gal. nitrous oxide cylinders, and two on the left (6A) for two 40-gal. oxygen cylinders. These yokes are strongly connected to a solid brass segment (7), which is tunneled on each side so that

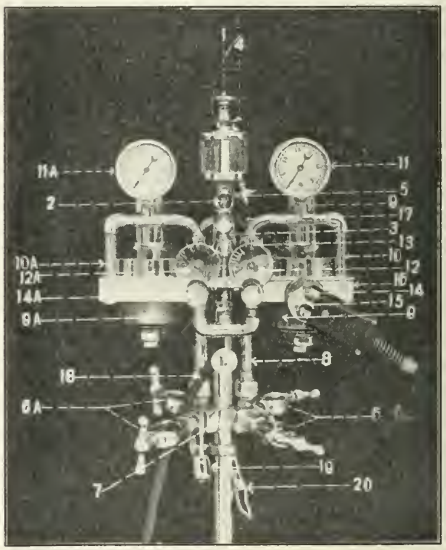

Fig. 1.

the gas from both cylinders may pass through it and upward through the high-pressure pipe (8), the oxygen taking a similar course on the left, thence entering the reducing valve (9), the oxygen passing through the opposite valve (9A). From these valves the gases pass through the low-pressure tubing (10, 10A) to the final control cocks. A low-pressure gauge of 30 pounds capacity is attached on each side (11, 11A), distal to the regulators, to indicate the pressure against these control cocks. The circular plates (12, 12A) are immovably attached to the stem of these cocks. A calibration appears on the upper part, which is read from a fixed indicator point (13) in the center at the top of each, in terms of liters per minute of the gas delivered to the rebreathing bag. On the lower side of this circular plate is a gearing which engages a pinion whose shaft is continuous with the two thumbscrew controls (14 and 14A). An electrical heating attachment (15) is built into the nitrous oxide con-

troller. This line is also tapped to provide a connection (17) for the ether heating device. The main portion of the apparatus, consisting of the center segment (7) supporting the yokes and all above this, is one connected unit, and may be raised or lowered by use of the spring catch (20) placed at the upper part of the supporting stand. If it is desired to use only one tank of oxygen and one of nitrous oxide on the machine, the two unused yokes are closed off by inserting into the same the two adjustable dummies or blanks (19). The one on the right, not numbered, is seen in position. The portable stand (Fig. 2) is light, strong, and can be easily taken apart and packed into a small compartment in the carrying case. The rubber outlet tubing (18) conducts the gases to the face mask.

A cut of the apparatus as recently made up for hospital use is shown in Fig. 4. A number of minor improvements have been made on this new model, but it chiefly differs from the original portable one by having a strongly constructed, non-collapsible stand which can be raised or lowered if desired. A larger ether reservoir has also been used here, and control cocks have been placed on each yoke, thus obviating the little inconvenience of momentarily turning off the supply of gas or oxygen to the rebreathing bag while a full tank is being inserted on either side in place of an empty one.

Calibration of the Instrument.—The volume of a gas delivered at a fixed and standard pressure (ten pounds in this case) through a graduated metal cock is very constant, and should remain so under such conditions for an indefinite period. In this apparatus a large cock has been constructed of hard composition-metal with an extra long tapered stem, accurately ground and fitted, having an offset to prevent leakage in the arrangement of the inlet and outlet channels. A pair of small, tapering V-shaped grooves in the stem in connection with the channels regulates the escape of the gases. For purposes of calibration a circular metal plate was attached immovably to the stem of the cock and a fixed indicator point arranged at the top of this plate. A reliable and proved dry gas meter of the three-light type was attached distally to the valve which was furnished with a gas supply at an even pressure of ten pounds. The cock was then opened to a point, for instance, where the gas meter indicated that the delivery rate was 2 liters per minute, then to a point where 4 liters per minute was delivered, and so on until on the nitrous oxide side a calibration was made for 2, 4, 6, 8, 10 and 12 liters per minute, while on the oxygen side the reading in liters was ½, 1, 1½, 2, 2½ and 3 per minute. Finer changes could be had by opening the valve to points between those placed on the scale. A manometer was attached distally to the meter and a resistance from 3 to 5 mm. of mercury was carried during the calibration, which would compensate for the slight positive pressure usually present in the breathing bag and mask. However, the effect on the amount of gases delivered is so slight that this is unnecessary.

Necessity of a Heating Device.—In a portable apparatus of this kind the small cylinders containing 40 gallons of oxygen and 100 gallons of nitrous oxide are mostly used. In the case of oxygen, where the tank pressure is about 1,200 to 1,500 pounds, it can be reduced and maintained at an even pressure of 10 pounds without difficulty, since it is used so slowly that a relatively small amount of cold is generated (average 1 liter or less per minute); but with nitrous oxide the rate is 4 to 6 liters per minute, and the ordinary controllers tend to alternately freeze and thaw after the first fifteen and twenty minutes, causing a continuous fluctuation of the low pressure. This must be overcome, since the accuracy of any measuring device for gases is dependent quite as much on the constancy of the pressure as on the amount of it. By the use here of a regulator having incorporated in its body a good electric heater it has been found possible to secure and maintain a 10-pound pressure continuously for long periods.

The Ether Device.—When ether is needed, it is, by the use of a direct thumb control at the top of the ether chamber, caused to be sent through the sight feed drop by drop into the electrically heated tunnel, through which all the gases are made to pass in a sweeping uphill direction, the ether tending to run downward against the oncoming stream of gases. This mechanical arrangement assists substantially in the vaporizing of the ether. The tunnel has, in general, the course which the letter U would indicate when the latter is placed on its side, thus ⊔; the space between the two limbs of the letter representing a receptacle for a tubular electric light which affords ample heat to prevent any freezing tendency of the ether even when being vaporized at the rate of 60 to 120 or more drops per minute. This heater can be disconnected independently, and need only be used when rather large amounts of ether are called for.

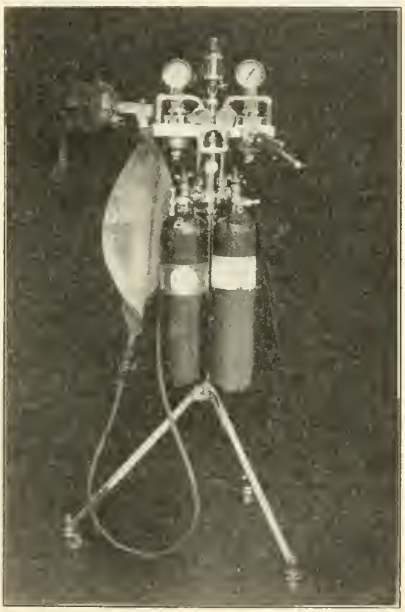

Fig. 2.—Portable apparatus; weight 22 lbs. without cylinders.

The Face Mask and Other Parts.—In an effort to simplify the portable apparatus and lessen its weight, turn-off valves have not been provided in connection with the yokes, but instead two light adjustable dummies or blanks, one on each side, are available to lock in the unused yokes in case only one tank is inserted on each side. The conducting tube from the instrument to the rebreathing bag

should have about one-quarter inch inside diameter, and be relatively short, that is, about 4 feet. The reasons for this are, first, to avoid possible accumulation of expired gases in the tube, and, secondly, to allow the quick delivery of fresh gases into

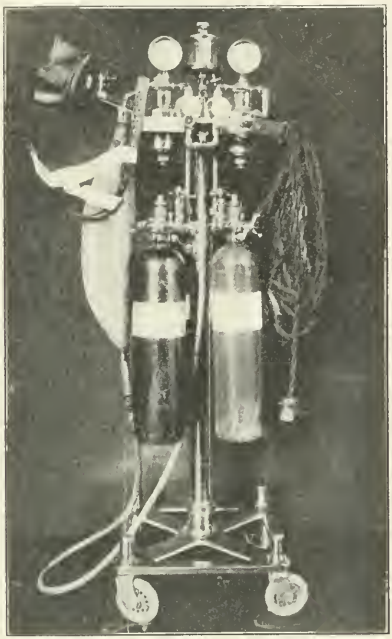

Fig. 4.—Hospital apparatus.

the rebreathing bag. The rebreathing bag is placed next to the face piece, thus facilitating the ease of respiratory interchange which would not be obtained were a long, rigid tube to intervene between the mask and working supply.

The Boothby-Cotton rubber face piece, an improvement on the one originally devised by Gatch, has been modified here by providing extensions at the chin and nasal ends, and attaching the retaining straps at a more acute angle with a double adjustable loop to fit over the crown of the head, thus leaving the back of the neck, so often the site of abscesses and carbuncles, free as a field for operation. A celluloid hood is used, and the metal parts of the mask are of light weight so that the rubber face piece, with its adjustable strap, makes the mask practically self-retaining. The exhalation valve has been specially designed, and regulates the ventilation very evenly. It consists of a valve seat, above which is a flat, circular aluminum float, which rides freely up and down on a small triangular-shaped vertical standard running through its center. The float is kept seated by a very delicate adjustable coil spring. The valve is all metal, and can be easily taken apart and boiled. The rubber face piece can be briefly boiled many times without serious damage; but the celluloid hood* should be sterilized in bichloride or oxycyanide of mercury solutions.

General Technique and Use of the Instrument.—In advance of the actual administration it is very important to give some alkaloidal adjuvant, since gas-oxygen as compared with ether or chloroform is just a veneer form of anesthesia. In the average case we have found that morphine sulphate, 1/6 grain with hyoscine hydrobromate, 1 200 grain, given together, hypodermically, one hour before operation is very safe and satisfactory. Where a definite contraindication to the use of hyoscine exists, atropine sulphate, 1 100 grain may be substituted. In the old and the young we usually omit the preliminary medication. The morphine, aside from its general sedative effect, is an efficient aid in blocking shock, while hyoscine gives substantial help through its powerful cerebral sedative action. It should also be remembered that at the start a word of explanation and encouragement to the patient but seldom fails to do real good, and frequently helps materially to accomplish a quiet, smooth induction.

The ether reservoir should always be filled, and the cock on the pipe running downward at the rear opened. This pipe serves to equalize the air pressure in the reservoir and vaporizing chamber, thus allowing the ether to escape freely from the former. One should also be certain beforehand that an ample supply of gas and oxygen is on hand. Our experience with this particular instrument indicates that in the average case a 40-gallon tank of oxygen will suffice for about two hours (average rate of 1 liter per minute), and a 100-gallon tank of nitrous oxide is usually sufficient for about 1 hour and 10 minutes (equal to 4.84 liters or 1.28 gallons per minute). Amounts of oxygen in excess of the average, up to 2 liters per minute, are occasionally required, because, as Connell has mentioned, a diminished tidal volume, a decreased oxygen carrying capacity of the blood or rate of blood flow must be compensated for by increased oxygen supply. Practical examples of this are seen in the case of young children, old people, individuals with marked anemia, septic cases, those with diminished pulmonary capacity, as in advanced tuberculous conditions, pneumonia, empyema, etc., uncompensating cardiac cases, and conditions of inanition, exhaustion, and shock from various causes.

Where excessive amounts of oxygen are demanded in cases not exhibiting such deficiencies it is usually

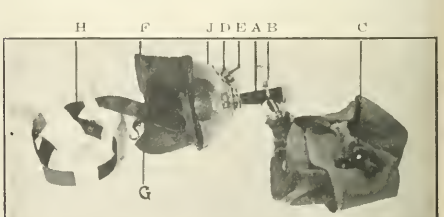

Fig. 3.—The face mask. The body (A) is of light weight and can be rotated in any desired direction. The thumb control (B) when pushed to the right to limit of slot opens an air vent on the opposite side of the body; in its present position the air vent is closed and free interchange of gas is allowed between the rebreathing bag (C) and mask. The exhalation valve (D) has a thumb screw (E) to regulate the tension of its spring. The nasal end (F) of the rubber hood shows the rubber flap beneath which cotton is packed on each side, while G indicates the chin extension. H is the head strap and J the celluloid face piece.

due to partially obstructed breathing. A free airway, indicated by a quiet, regular respiratory rhythm, is of paramount importance. To obtain this some mechanical aid is frequently necessary, and we have found that the simplest, least expensive

*An aluminum hood will be tried in the near future.

and most practical device consists of a pair of fairly soft rubber tubes of about ⅜ inch bore, the ends to be passed into the mouth over the base of the tongue being beveled and seared in a flame to make them smooth, while the opposite ends which protrude beyond the lips are pierced by a strong safety pin, which is locked and has attached to it a loop of tape 6 inches long, which will extend from beneath the mask to the outside. They are simple to make, can be used several times, and are readily sterilized by boiling. If sterterous breathing with cyanosis persists one should expose the mouth by raising just the lower end of the face piece, and with firm downward pressure of the chin by the left hand, if necessary to overcome the set jaw, quickly pass with the other hand the tubes, previously smeared with a little K-Y lubricant, between the teeth and over the tongue until the pinned ends extend just beyond the lips. By this device a troublesome and often dangerous anesthesia is quickly converted into one which is smooth-going and satisfactory, and it should always take the place of constant jaw pressure, which is irksome, inefficient and harmful. During the past four years this device has been used in about five thousand cases of general anesthesia at St. Luke's Hospital with the utmost satisfaction.

Before adjusting the mask the air vent on the body of same should be closed; this locks in the bag any gas turned into it. One should next fill the bag about three-fourths full of pure gas, avoiding delay by opening the gas valve to the limit. This done, the gas is turned off completely until the rubber face piece, a modification of the Boothby hood, is arranged. It has at one end an extension which hooks over the chin and lifts it somewhat, thus encouraging the forward position of the lower jaw when the retaining strap which goes over the crown of the head is pulled fairly tight and fastened. The nasal end fits snugly over the bridge of the nose, but does not bind. Beneath the rubber flap on each side of the nose should be tucked a moderate-sized wad of non-absorbent cotton. This gives a snug fit along the side of the nose. The air vent is now closed, allowing free flow of gases into the face mask while the gas valve is opened to the point indicating 6 liters per minute, and the oxygen valve set at the ½-liter mark. When the slightest bluish tinge appears in the ear (the most practical place to observe color) the oxygen is turned up to the 1-liter mark. Later, consistent with the behavior of the patient, it may be and often is possible to decrease the gas delivery to 4 liters per minute, while the oxygen indicator may usually be held at or a little behind the 1-liter mark. However, in intractable patients, such as alcoholics, large muscular men, highly nervous individuals, etc., as much as 8 liters of gas per minute may be required throughout. This is also the case where the tidal volume is much increased, due to very rapid and deep breathing. With the gases delivered at the average rate, as mentioned above, the tension of the spring in the exhalation valve should be so adjusted that the rebreathing bag at the end of expiration is completely filled without being tense. Positive pressure is unnecessary and is advised against.

It should be remembered that it requires from seven to ten minutes to establish a good gas-oxygen anesthesia, which does not mean the mere state of unconsciousness usually obtained in from fifteen to forty seconds, but a balance of gases between the alveolar air and blood which will maintain a sufficient saturation of the nerve centers to obtain the most complete anesthetic state without the presence of anything more than a very slight degree of cyanosis.

Ether as an Adjuvant to Nitrous Oxide.—It is during the induction period when a relatively light anesthetic state exists that the moving and placing of the patient in special positions, followed by the powerful reflex stimulation of the skin incision (where no local anesthetic is used), and this in turn perhaps by intraabdominal manipulations, that offers some of the greatest difficulties to overcome with this anesthetic. Ether is a powerful synergist to nitrous oxide, and it is due to this fact that a pronounced quieting effect is frequently observed during the induction period when very small amounts (2 or 3 drachms) are added at the rate of 40 to 60 drops per minute over a period of three or four minutes. After this in a majority of cases no more ether will be required, but a certain percentage of these will necessitate a small amount again at the time of closing the wound, especially when it is in the upper section of the abdomen.

In certain intractable cases it may be necessary to continuously add a little ether (20 or 40 drops per minute) throughout the operation, and at the same time it is usually best, though not absolutely necessary, to increase the oxygen percentage sufficiently to obtain a pronounced pinkish color. The use of local anesthesia in the line of incision, if surgeons could be induced to use it routinely, would conduce to a much more quiet anesthesia, far better muscular relaxation and minimize the necessity for the use of ether as an adjuvant.

At the commencement of this article certain requirements were set forth as representing the writer's idea of a clinically efficient and practical gas-oxygen apparatus. It is believed that all of these have been attained in the instrument here described, and the final test, its practical utility, has been satisfactorily established during the past three months in St. Luke's and other hospitals here.

204 West 110th Street.

THE INFECTED COLON AND ITS SURGERY.*†

By J. M. LYNCH, M.D.,

AND

J. W. DRAPER, M.D.,

NEW YORK.

(*Introductory Note.*—This paper is not a plea for either so-called surgical or medical therapeusis, but a simple chronicle of certain facts which the authors have obtained through experimentation on animals, through laboratory studies on human material, and from clinical results.)

Bouchard, after Claude Bernard, gave added impetus to the study of autointoxication. Roger, Metchnikoff, and Combe, working along somewhat divergent lines, have made our knowledge of this interesting symptom-complex more complete. Adami, after reviewing this earlier work in collaboration with his own extensive studies, concluded

*Read at the meeting of the Medical Society of the State of New York, April 27-29, 1915.

† Studies from the Surgical Clinic of Colonic and Rectal Diseases, New York Polyclinic School and Hospital and from the Laboratory of Surgical Research, New York University.

that the process should be properly considered a subinfection of bacterial origin. Combe believed that the origin of the toxemia was to be found in the bacterial hydrolysis of the proteins. Metchnikoff was also inclined to this view and most of the present day therapeusis is based upon this conception. His idea is that the protolytic anerobic bacteria are the toxic agents—these thrive best in the alkaline secretion of the cecum and cecocolon. That the reaction of the ileum is acid is taken to explain the fact that these bacteria are seldom found there save under pathological conditions. Under this hypothesis originated the sour milk, lactic, and succinic acid treatments.

From a surgical standpoint it is necessary to include not alone the lesions caused by substances formed through the vital processes of the organism, which is Combe's conception, but also those arising from destructive infection of the bowel wall, which in a sense is not true autointoxication, but which is essentially a surgical disease. Surgeons can at present do no better than find a means to prevent the absorption of the toxins from a given part of the bowel, however these poisons may have been created. Thus, we limit ourselves here to a consideration of partial obstructions by whatsoever cause, and of colonic infections which are destructive or inhibitory of the normal functions of this part, particularly those functions which protect the body from infection. This amounts to nothing more than a conservative extension of surgical therapeusis to the colon. Does it not seem logical to apply the same surgical principles to the colon as to other organs? Most acute and chronic purulent colonic infections are surgical from the start, and the future functional efficiency of the organ and of the individual depends upon early recognition and proper treatment.

The colon is pouched at either end, and its entrance and exit are guarded by valves. It is widest at the cecum and narrowest at the rectum. Four angulations give to this organ potent pathological possibilities. Three gross features distinguish it from the small gut: (1) The teniæ, (2) the appendices, (3) the haustra. Not being a highly specialized organ, the colon is subject by the laws of heredity to great variations both of size and of position—specialization results in a rigid adherence to a fixed form. The greatest variations are seen, as would be expected, in the cecum and sigmoid. Microscopically, except at the apex of the cecum, the most important surgical consideration is the relative scarcity of lymphatics and the absence of villi. This suggests what has lately been proven: that the digestive function of this organ is nil. Auerbach's plexus has recently come to be of great surgical importance because of our increasing surgical interpretation of the function of the autonomic system. The terminal ileum, the appendix, the cecum, and colon have a common origin. This has an important bearing upon surgical physiology. Obviously, the entire alimentary canal, particularly its caudal portion, is ill-adapted to the gravity strain incident to the upright position, even when the support and the torsal development have been most favorable.* A consideration, therefore, of the biological forces constantly at work is of great interest to the diagnostician and to the operating surgeon. Hereditary tendencies resident in the germinal material itself, lasting throughout life, and those imposed by the peculiar conditions of man's environment, combine to yield a high percentage of ill-adapted cecocolons. Bryant has shown that an herbivorous and a carnivorous classification of human disease is possible, and it is evident that in no part of the body is this more true than in the cecocolon. Man's cecum is normally carnivorous in type.

There are three deviations from the normal course of enteric development which are of great surgical interest. Rotation may fail; fixation may fail; the cecum may conform to the ancient herbivorous type. Any or all of these variants may, under pressure of gravity, produce areas of dilatation and atonicity which result in a slowing of the intestinal current, frequently ending in infection. Is it not easy to see that, given a cecum of this ill-adapted, pseudo-herbivorous type, it may undergo changes in the following sequence; stagnation, gas formation, dilatation, attenuation, infection, destruction of Auerbach's plexus? Barber has shown in recent animal experiments the important difference in the character and location of the dilatation following partial and complete obstruction. In brief, partial obstruction of the colon caused dilatation of the duodenum only, while complete obstruction caused contraction of that organ and colonic dilatation just orad to the obstruction. An analogy may be drawn between this process and that which destroys so many gallbladders and appendices. The difference is that we have come to a recognition of the one, but not, as yet, of the other.

Bloodgood has observed a vast difference in the postoperative behavior of his colonic cancer cases and those in which the colon has been resected for other causes. There was a rapid restoration of function in the cancer cases, but when the colon was resected for other causes the return of function was slow and often incomplete. These observations accord with our own, and we consider the following to be a possible explanation.

The earliest sign of cancer is constipation. This occurs irrespective of the size of the growth or of its encroachment upon the gut lumen. It is equally true of laterally implanted growths, as of the annular types. It is next to impossible, either by catharsis or enemata, to empty the bowel of the fecal mass which accumulates in the dilated pouch just orad to the growth. We have confirmed these observations repeatedly, especially in the case of minute recurrences which could not possibly in themselves offer any excuse for mechanical obstruction, the bowels having been regular since the primary resection and up to a short period before the recurrence. This inhibition is perhaps associated with Nature's effort to cause a recession of the growth. It is common practice to associate diarrhea with a new growth, but, of course, diarrhea is no evidence of the absence of constipation, for paradoxical as it may seem, the diarrheas most persistent are those associated with constipation. This frequent and imperative desire to defecate is not properly a diarrhea, but a mere subjective reflex without objective basis. So often is a diarrhea of this kind mistaken clinically, and so closely may it appear to be allied to the inflammatory conditions of the colon that one cannot consider them true inflammations without mentioning malignancy. We think it would be well to confirm or disprove our findings, that often the earliest clinical sign of cancer is a relatively sudden constipation.

*Shaler considers that the upright position more than any other single factor has fixed the short limits of man's life.

In our studies we have noted that colonic infection appears to bear a measurable ratio to the degree of morphological variation from the normal occurring in the organ or in its mesentery. Furthermore, of the fifteen ceca removed and studied microscopically and found diseased as per the following reports, all showed inflammatory change. Of all the other cases in which developmental reconstruction was not done, but rather a simple colostomy or ileostomy, not one organ conformed to what is considered anatomically normal.

Infections of the colon vary from a mild catarrhal inflammation to the most severe involvement of the entire wall and the seroperitoneal fat. While as yet we can offer no conclusive evidence upon which to base a rigid classification of colonic infections, it is evident, clinically, that there is wide variation in the course pursued by the infection, in its position, its virulence, and its outcome. Some infections, and these are frequently seen in the infantile or fetal type of cecum, are confined more or less closely to the cecum and cecocolon. This may be because of the direct continuance here of the cecal and appendicular walls. Of this interesting relationship there is no direct proof, but a further series of observations might prove the hypothesis, namely, that the cecocolonic infection was primarily of appendicular origin. In discussing the origin of colonic infection our laboratory colleague, Dr. McFarland, suggested that here as elsewhere the hematogenous pathology of infection was deserving of careful consideration. The virulence is to be measured in terms of physical and mental systemic disturbance rather than in the amount of blood and mucous in the stools. Here, as elsewhere, the streptococcic infections are most serious, although in a woman who was completely disabled mentally and physically we have isolated a pure culture of colon bacillus from a gland found in the cecal mesentery.

The outcome of colonic infection is most interesting because of an apparent paradox. The virulence of the infection is no index of the degree of subsequent strictural deformity. The infections which usually result in stricture are comparatively mild. We have seen very severe streptococcic infections leave no deformity whatever.

Case 259.—A railroad engineer. Clinically mild infection; passing blood and mucous, but able throughout to run his engine. Proctoscope showed a colon inflamed in spots, which bled easily on the slightest touch, covered with mucoserum. No ulcers whatever. Sick for six years. Gradual narrowing of descending colon to complete obstruction under medical and incomplete surgical treatment. Cured by exclusion of entire descending colon which is permanently destroyed.

Case 254.—A young society woman. Severe constitutional symptoms. Proctoscopy showed a seropurulent exudate and some ulceration. Microscopic examination of colon revealed an acute hemorrhagic inflammation of all coats, including peritoneum and adjacent fat precisely like that of carbolic or arsenical poisoning. The *Streptococcus viridans* was recovered from the discharges. Nevertheless, after appropriate surgical treatment, although she had been medically treated for a year and a half previously without improvement, she has gained thirty-five pounds and, clinically, the bowel is functionally perfect.

These represent the end results of two extremes of colonic infection, and many cases approaching the mean, serve equally to support the hypothesis stated above.

The general indications for surgical intervention are to be sought and found only after a most exhaustive study of each individual patient. First to be considered are the grossly evident colonic lesions. Rare, but prominent among these in point of importance, is hemorrhagic colitis. This embraces the following conditions: Acute streptococcic embolic septic colitis; chronic torpid ulcerous, slowly progressive colitis; acute diphtheroid hemorrhagic colitis. These forms of colitis yield only to surgical therapeusis. It is evident that no good purpose can be served by partial removal, because the colon is, as a rule, diseased from the ileocecal valve to the anus, and no one would here think of extirpation. It is a curious fact and well worthy of note, that the infections terminate abruptly at the ileocecal valve. This occurs in spite of the fact that since the terminal ileum and the cecocolon have a common embryological origin one would naturally expect them to be susceptible to like infections. For it is undoubtedly true of the ileocecal valve, as has been proven true of the ureterovesical, that its power of preventing so-called ascending infection is almost nil, the physiological function of the ureter being paramount. Our clinical observations on the Bauhinian valve all tend to show that this is equally true of the gut, for ileac involvement is extremely rare except the gut functions be impaired by bands or adhesions, and quite irrespective of the valvular patency. This view is at variance with that of those surgeons who operate for the sake of restoring the valve. Further research here is evidently necessary. Thus, it appears to the essayists to be as yet an open question whether the immunity enjoyed by the terminal ileum, though it be the embryological analogue of the cecocolon, is due to the change in chemical reaction, or, as with the ureter, to a protection afforded by its unimpaired physiological function.

Whatever the cause of so-called hemorrhagic colitis, one thing is certain: though the clinical pictures may be almost identical, the histological findings are absolutely different. Undoubtedly, the infections must be as varied as the microscopic pictures. Bacteriologists are helpless to aid the clinician in reaching a specific basis for classification, and until they find it possible to interpret the clinical findings in a scientific manner we cannot hope to reach a satsfactory classification, nor can we hope to treat these cases in any way other than by operation.

The histological findings in support of our premise are as follows:

The first case shows acute inflammation from the mucosa to the peritoneum. No desquamation of epithelium or destruction of glands. Submucosa shows both acute and chronic inflammation. The muscularis in some places is normal and in others chronically inflamed, with entire absence of nerve tissue. The discharges in this case are foul smelling and dark brown. The peritoneal gut is much thickened and appears in the form of a dense fibrocellular membrane which is only loosely attached to the muscle. The appendix is the seat of acute purulent inflammation. The mucosa shows leucocytic exudate with blood and pus.

In the second case the mucosa differs in that it is very deeply congested and has the appearance of the mucosa of carbolic acid or arsenic poisoning. In all sections in this case the entire mucosa is covered by exudate and presents a picture of intense inflammation. The blood vessels are greatly distended, but there is no evidence of degeneration of epithelium. The submucosa exhibits both acute and chronic inflammation here, also blood-vessels

are dilated and engorged with blood. The musculature shows some process of acute inflammation and the blood-vessels are engorged with leucocytes. There is exudate scattered through the submucosa. Tubercles can be demonstrated, but are not of tuberculous origin. There are several giant cells. A careful study of the nerve tissue fails to give any evidence of participation in the inflammatory process. The musculature shows evidence of acute inflammation and the peritoneum forms a dense fibrocellular membrane which is adherent to the muscle.

The third case presents exudate throughout, but most marked in the mucous peritoneal coats. The crypts of Lieberkühn have been entirely replaced by a round-celled exudate. Blood-vessels are abundant and engorged with blood. They are very numerous on the free surface of the mucosa. Apparently there is total absence of submucosa, in consequence of which the exudate layer replacing the mucosa rests directly on the inner muscular coat. There is round-celled infiltration of the muscular coat. There is no change in the peritoneum in this case.

Having considered the hemorrhagic form in a special manner, because of its severity, rarity, high mortality, and exceptional import to surgery, we turn to the more frequent infections, local and general. There are all grades of infection varying from very severe to mild. Some are merely catarrhal manifestations of direct extensions. Note the colitis from adventitious bands, from recurrent injury by floating kidney, and from contiguous pus tubes and gall-bladders.

Case 487.—A woman of 49. Abdominal tumor removed nine years ago. General complaint, pain, loss of strength during the last five years. Secondary complaint, constipation, alternating with diarrhea. Medical treatment futile. Operation, mesoventrad incision showed omentum thickened, twisted upon itself, and rotated from right to left so as to produce a partial hour-glass stomach and a triple kinked and twisted mid-transverse colon. It is well shown in the color photograph. Cessation of symptoms since operation, one year ago.

It is surprising how slight the physical basis may be in order to cause a disability out of all proportion to it. The following case is illustrative.

Case 362.—Constant diarrhea, blood mucus, and tenesmus. Nausea and gastric symptoms so marked as to have deceived a very prominent stomach specialist who considered the lesion to be gastric ulcer, and who treated it as such for several years. Cured by the simple removal of a polypus from the sigmoid.

Time will not permit us to consider tuberculosis, syphilis, diverticulitis, and many other constitutional and congenital conditions. Suffice to say, that all require surgical treatment, the technique and details of which are well known.

We wish to emphasize here particularly the surgical therapeusis of certain special forms of colitis which have given brilliant results in our hands and which we believe are not in general use. This therapy depends upon the following simple axioms. *A stoma situated anywhere but orad to all the inflammation is worse than useless. Colonic resection, to succeed, must be based upon surgical physiology.* Thus, the therapy under discussion consists in providing for one class of cases, rest; for the other, resection. A differential diagnosis to determine in what class a given case will fall may be established as follows:

What are the indications for ileostomy; what for colostomy, and what for resection? Acute purulent hemorrhagic and the acute purulent inflammations of the colon differ in this respect. The first is usually a general infection of the entire colon and rectum, ending in death under ordinary treatment. Prostration is profound, temperature high and irregular, and the anemia is severe and progressive. The discharges have a particularly foul odor, and the pain is cramp-like. There is no condition in the whole range of surgery more certain to yield a brilliant result if ileostomy is done in time. Appendicostomy and cecostomy will not cure; they are inadequate and are contraindicated because unphysiological. Their use in this type of case is unwarranted, and gives a striking example of meddlesome surgery.

Another rare condition previously treated by irrigations and medication and occasionally by colostomy, is multiple polyposis. Ileostomy is the proper therapy. This lesion we believe to be secondary to an infection and the histological findings tend to support this view.

Case 180.—Diarrhea alternating with constipation. Abdominal pain and tenderness. Frequent mucus and blood in stools. Illness began in summer of 1900 and from that time up to May, 1912, the patient had acute exacerbations with intervals of freedom. Bowel was studded with growths varying in size from small pimples to those three-quarters of an inch in length and one-half inch in diameter. They were so thick that it would be almost impossible to put the finger on the bowel without touching one. Mucous membrane granular in appearance and inflamed and covered with pus. Operation in May, 1912, ileostomy. Following this appetite improved and patient was able to eat anything without discomfort. Gradual gain in weight from 137 pounds at time of operation to 152 pounds one year later. At present (1915) weighs about 160 pounds. When last seen the bowel was normal and there was no presence of any of the growths, mucus, or blood.

Case 254.—Chief complaint, epigastric pain, heart burn, diarrhea, foul smelling, dark brown discharge. Ileostomy and subsequent gain of 35 pounds. Patient danced all one winter with ileostomy opening and none of her friends suspected its existence. A year and a half after operation, cured. About six months have elapsed since opening was closed. Since then several examinations have been made for occult blood and the report has been negative on each occasion.

The causative relationship of infection to polyposis is further supported by the fact that after ileostomy the inflammation subsided and the tumors disappeared.

The third colonic lesion to which we have given special attention is a local infection of the cecocolon, a typhocolitis not extending far beyond the hepatic flexure, and giving systemic symptoms of profound auto-intoxication. These cover a wide field of human ailments and are familiar to all.

The indications for laparotomy in cases not yielding to colonic vaccines and other suitable forms of medical therapeusis as described by Satterlee, are chronic intractable constipation or diarrhea plus the characteristic mental lesions, together with *x*-ray findings and often with snow crepitation over the cecum.

Resection is indicated if a non-fused, inflamed, thickened, dilated, infected cecum often with a mesentery studed with enlarged lymphatic glands is found. As yet we have not been able to decide positively upon resection until after laparotomy. As resection is a vague term, not indicative of any particular technique, we have suggested the term developmental reconstruction in a previous paper. This embodies the resection en masse of the terminal ileum, appendix, and cecocolon to the region of the middle colic artery. When completed, it

places the ileocolic juncture in the position occupied before birth, which is the adult position in the dog and may, therefore, be termed "developmental." This operation carries a mortality which is far from negligible and has been practised by us only on individuals who have had years of unremitting, unavailing medical treatment and who were in every way unfit. Of a series of thirteen, 23.1 per cent. died, 46.2 per cent. were cured, 23.1 per cent. improved, and 7.7 per cent. not improved.

We have made several observations during the post-operative history following reconstruction, which have been of value to us and may be worthy of record. The first is, that reaction is apt to be severe in proportion to the amount of handling in the neighborhood of the second portion of the duodenum. We have, therefore, recently taken great pains to avoid this, considering that it may have something to do with the sympathetic ganglion and plexus known to exist there. Another observation is that reaction, if present, is apt to be delayed until after the fiftieth hour. Still another is that at least one among our cured cases was unquestionably saved through the administration of autogenous vaccine by Dr. Satterlee.

We never use saline solution in the rectum, first, because it is contrary to the laws of osmosis; second, because the salt increases the patient's thirst, and third, because there may be a considerable toxic element in so large an amount of sodium chloride. We give forty to sixty drops per minute of tap water by rectum after the patient is returned to bed and continue as toleration may permit throughout the first week. We are convinced by experience that the rate of absorption of tap water is so rapid that no possible danger can exist from its use, and this is further supported by the experimental fact that the colonic wound is normally sealed within two hours after its closure.

The postoperative care following ileostomy or colostomy is exceedingly important. It means comfort or discomfort to the patient. In the first place, if possible, the bowel loop should not be opened until the fourth or fifth day after operation. The efficiency of a colostomy is to a great extent dependent on primary union of the wound; if this fails the patient may have a hernia superimposed on the colostomy, and this means discomfort and inefficiency. On account of cramplike pains and accumulation of gas, the patient is often so uncomfortable that it is imperative to open the bowel by some method in order to afford relief. On more than one occasion we have accomplished this by passing a small trocar and cannula and allowing the gas to pass out in this way. We have occasionally used a small number ten or eleven French catheter, and closed the bowel with a purse-string suture. This at times is very satisfactory. There is one important feature connected with ileostomy which we have learned, and that is to anchor the ileum to the abdominal wall about ten centimeters orad to the proposed stoma. This prevents prolapse and inconvenience; also prevents its buckling against the other side of the bowel and permits it to pass into the cecum. The proper care of the skin and provision for enteric drainage are points not to be overlooked. An ointment of zinc oxide, having for its base lanolin, should be applied to the skin for a radius of about five centimeters from the stoma all around; over this some fine starch powder should be dusted. A collar of two or three thicknesses of gauze will serve further to protect the parts. A bag with the rubber container at right angles to the collar, such as is made by Tiemann and modified by Dr. Treby Lyon, one of our associates, serves as an emergency receptacle in case of leakage. This, however, is not to be expected, at any rate, not after the new function has been established. The use of a receptacle is not always necessary following a colostomy, but it is imperative following an ileostomy.

Although the readjustment of physiological balance after ileostomy, particularly in relation to the absorption of water, may take place slowly, it has come in due season in all of our cases. The stoma is not so efficient as after colostomy, but this is largely compensated for by the sticklike character of the movements and by the relative absence of gas of fecal odor. We wish to emphasize what we have already published, that the fear of post-operative discomfort both from colostomy and ileostomy is grossly exaggerated.

In conclusion, we wish to emphasize the most careful differentiation of all colonic inflammations, not alone as to character, so far as that be possible, but particularly as to distribution. Some infections are general, others segmental; the therapeusis rests largely upon this, an ileostomy being indicated for the one, a colostomy or a developmental reconstruction for the other. Many segmental infections, unless surgically treated, even though relieved and apparently cured by medical treatment, invariably relapse. Cessation of symptoms for a time does not mean cure. Such infections almost invariably end in stricture, so its preventive treatment is the early recognition and surgical treatment of the cause. Whatever the nature of the primary infection, it always becomes mixed after a short time. This principle underlies the therapy of the colon just as thoroughly as it does that of the lungs.

Heredity and the upright position play important parts in colonic pathology, and sympathetic recognition of man's place in Nature is an important step in directing colonic therapy.

Ophthalmology in War.—M. A. Darier calls attention to the great frequency with which wounds of the eyes occur during war and insists upon the importance of the special service of ophthalmologists among the medical personnel of the army. The first aid should be prompt, and should consist in the observance of strict asepsis and the use of a mild and efficient eye-wash. Morphine should be administered in cases in which the pain is very severe. The use of antitetanic serum may be resorted to with advantage.—*Presse Médicale.*

A RATIONAL AND SUCCESSFUL TREATMENT FOR PULMONARY TUBERCULOSIS.

By A. H. HENDERSON, M.D.,

AMERICAN BAPTIST MISSION TAUNGGYI S. SHAN STS.

In outlining the treatment below I hope that I shall not only be helping fellow practioners in the fight we are all waging, but also adding to the life and comfort of the victim of this dread disease. The reasons for the choice of the first adjective in my heading are the following:

1. While in college, Prof. W. H. Thomson, our professor of Materia Medica, called our attention to the fact that it was the combination of the tubercle bacillus with the pus bacillus that made it so deadly; if we could get it single, the human body could fight with winning chances, and people would recover from pulmonary tuberculosis.

2. Within the past few years, experience has taught me more and more that we have an agent that will control pus formation. I refer to calcium sulphide, which has from time to time been mentioned in the Medical Record, particularly by my confrère in missionary work residing in Turkey, as a treatment which will prevent the formation of pustules in smallpox. Putting these two facts together I reasoned that in calcium sulphide we ought to have the foundation stone for a successful attack on our stubborn foe.

The employment of the second adjective is of course premature, but seeing that treatment along these lines has, in the limited number of cases in which I have been able to use it, borne out the reasoning, we can claim success at least until it is disproved. Let me urge, however, that fresh preparations of calcium sulphide are needed.

Case I.—K., started in over two years ago with hemorrhage, cough, fever, much expectoration, and well marked, rather diffuse, signs of tuberculosis mostly in the left lung. Treatment with calcium sulphide was begun, six grains a day in three doses. All expectoration and fever soon disappeared. He has never had any more hemorrhage; the tuberculous process is still active, as is evidenced by indurated spots and some pain in the chest, but the process is absolutely dry, no moist râles being heard. He has resumed his work which was laid aside, is holding his weight, and says that he feels as well as he ever did. He has continued steadily with the calcium sulphide in doses of from 6 to 8 grains a day without any digestive or other trouble from it. Cod liver oil and creosote were used with the other treatment and with these he held his own.

Case II.—K. B., started in in much the same way, about the same time, only that his case was complicated with malarial fever. Same treatment and same results except that as he has been less faithful in the use of the pills he has some cough still, but no expectoration. The last examination of sputum some eighteen months ago showed the bacilli clubbed.

Case III.—S., carried in to me from a village about three miles out. Unable to walk, septic temperature, abundant blood-stained purulent expectoration and seemingly in the last stages of consumption. I gave him about a month to live, but gave him the chance of trying the treatment at home. Calcium sulphide, creosote three grains a day, and cod liver oil. He reported that his cough was disappearing, sputum no longer bloodstained, fever subsiding, and he was beginning to walk about. Some three months later he walked into the dispensary so well and healthy looking that I did not know him. Unfortunately he has now discontinued the treatment and his symptoms are coming back.

Case IV.—Pulmonary abscess. A fellow practitioner in Rangoon to whom I had spoken of these cases used the calcium sulphide in a case of pulmonary abscess and reported to me a simply astonishing cure. For the septic fevers it is the drug par excellence. We do not have scarlet fever out here, but if ever I had another case to treat I should certainly try the calcium sulphide and expect largely to modify its course.

It will be seen above that the treatment is on two lines: (1) Attack with the calcium sulphide, and (2) Defence with all the well known remedies, but the former drug is the axe at the root of the tree. I shall be greatly interested if others will try and report on this line of treatment, for the circumstances and isolation of my position here preclude any extended personal observations.

The large doses were given because I could not closely watch the cases. I could only see them at intervals and wanted to give enough to secure results. There has been absolutely no bad effect.

Finding that others had written along this same line I did not forward my article when it was written (June 29, 1914), but do so now (Feb. 9, 1915) for two reasons:

1. I notice several are favoring calcium for tuberculosis, and this may explain some of the action of the sulphide.

2. Since writing, Case 1, after feeling exceedingly well, had an attack of influenza with bloody expectoration. His temperature ranged from 101 to 102 in the afternoons and slight hemorrhages occurred at intervals for three or four days. Between whiles his expectoration was free but, as he described it, "like the white of an egg," in other words, free from pus. He is now at work again.

Medicolegal Notes.

Action for Medical Services—Evidence.—In an action for medical services rendered to a third person at the request of the defendant it was held that a statement filed with an insurance company by the third person, in which after setting out the facts of the accident he stated that he thought he was entitled to his lost wages and doctors bills and that the doctor's bills amounted to $150, was inadmissible against the plaintiff in the absence of any evidence that such statement was brought to his attention.—Hertel vs. Cuba (Mo.), 171 S. W. 565.

Expert Testimony as to Character of Wound.—In a case of homicide caused, in a physical struggle, by strangulation, according to expert and uncontradicted evidence, it was held to be competent for a physician who performed or assisted in performing an autopsy upon the body of the deceased to state an opinion as to the nature, character, and cause of a bruise or scratch on the defendant's face, which he examined or observed on that occasion, and to say it was a fresh break of the skin, that it had in it fresh blood, and that in his opinion the break in the skin was caused by a fingernail. Other witnesses observed the same marks and expressed the same opinion without objection. The injured part could not for obvious reason be produced upon the trial in the condition in which it at first appeared. Without such evidence the jury could not form any definite conclusion as to its nature, cause, or character.—State vs. Gunnoe, West Virginia Supreme Court, 83 S. E. 64.

Cross-Examination of Medical Experts as to Medical Authorities.—In an action for wrongful death claimed to have been caused by the defendant's act in compelling the deceased to remove from the cottage which she was occupying while she had typhoid fever it was held that testimony by medical experts that the removal was the cause of her death was not an invasion of the province of the jury, but was legitimate opinion evidence, being predicated upon the symptoms of the patient and attendant facts assumed to have been found by the jury. A medical expert who had treated the deceased testified for the defendant in effect that the removal, in his opinion, "had not unfavorably affected the patient in this instance, and that on the facts of the case, would likely increase her chances of recovery." It was held proper for the plaintiff to cross-examine him as to whether all medical authorities did not teach that typhoid patients must not be moved, if possible, the question being put to test the value of the expert's opinion and not to put in evidence extracts from medical books.—Lynch vs. Rosemary Mfg. Co., North Carolina Supreme Court, 83 S. E. 6.

MEDICAL RECORD.

GASTRIC AND DUODENAL ULCER IN INFANCY AND CHILDHOOD.

As it is in comparatively recent years that the frequency and importance of gastric and especially of duodenal ulcers in the adult have been appreciated, it is hardly to be wondered at that these lesions in children have received scant consideration, particularly since they are comparatively rare in early life. Recently a number of valuable articles on these subjects have appeared, among which may be mentioned one on "Ulcer of the Stomach in Children Before Puberty," by C. D. Lockwood (*Surgery, Gynecology and Obstetrics*, October, 1914); another on "Duodenal Ulcers in Infancy," by Holt (*Am. Journal of Diseases of Children*, December, 1913), and a third with the same title by Veeder (*Am. Journal of the Medical Sciences*, November, 1914).

From the literature Lockwood collected 110 cases of gastric ulcer, and from correspondence, together with one case of his own, he added 15 hitherto unpublished cases. His studies show round ulcer of the stomach and duodenum to be relatively rare in children, but he believes it more common than most surgeons realize; and he also believes that many obscure abdominal symptoms which have been ascribed to appendicitis, gastroenteritis, etc., are due to ulcers. Welch found one case in a ten-year-old child in a series of 607 cases of gastric ulcer; and Wallenstein found five cases of gastric ulcer in 390 autopsies at the Babies' Hospital in New York. Lockwood also states that the pathology of peptic ulcer in children does not differ markedly from that in adults. The ulcers may be single or multiple. In very young children they are more often superficial erosions and the deep funnel-shaped ulcer so characteristic in adults is rare. In older children more typical ulcers are found and perforation is common. Ulcers in children are relatively less frequent in the pyloric region, occurring most often on the posterior wall, near the cardia, and along the greater curvature. Perforation occurs through the posterior wall into the bursa omentalis or through the lesser curvature into the pancreas. Many of the reported cases have been associated with tuberculosis and it is often difficult to distinguish simple ulcer from tuberculous lesions. Regarding diagnosis, Lockwood says: "Pain in the epigastrium, hematemesis, and bloody stools are conclusive signs. The two latter are usually absent and pain is often indefinite and not well localized. Pain, worse at night, loss of weight, and chronic indigestion are usually present. These symptoms should suggest ulcer; and physical examination, aided by microscopic examination of the stomach contents and stools for concealed blood, will render the diagnosis conclusive." Appendicitis seems to be the condition most often confused with gastric ulcer.

Holt collected from the literature 91 cases of ulcer of the duodenum in the first year of life and reported four cases from a total of 1,800 autopsies at the Babies' Hospital in New York. Veeder brings the number of reported cases up to 100 by adding 5 seen during a period of two years at the St. Louis Children's Hospital. In four of these a clinical diagnosis was made, confirmed later in three instances by autopsy, while the fourth infant recovered. The fifth case was found at autopsy, the lesion having been unsuspected during life.

The symptoms in Veeder's series of five cases were in part as follows: All of the infants were under six months of age and marasmic. All had vomiting. In a few cases the vomiting closely resembled the type occurring in pyloric obstruction and he believes that in all probability the mechanism is to a large extent the same—the ulcer situated just beyond the pylorus acting as an irritant, producing spasm of the pylorus. As Veeder says, there is nothing very unusual in the association of vomiting and food decomposition; but when massive hemorrhage from the bowel is added (in the absence of acute ulcerative lesions of the large intestine and other conditions, such as polyp, which cause hemorrhage) he considers the symptoms strikingly suggestive, if not pathognomonic, of duodenal ulcer. Holt found that bloody stools were observed in 28 of 64 cases in which the clinical histories were recorded, and they were present in 2 of Holt's 4 cases. Veeder points out that severe collapse has occurred in many cases accompanying and as a result of hemorrhage, and in some cases has apparently been the cause of death, and that the absence of subjective symptoms, which are of so much value in the diagnosis of duodenal ulcer in the adult, make the diagnosis dependent upon the association of the few objective symptoms described above. The presence of gross hemorrhage is the only definite symptom pointing to a duodenal ulcer and hence when this symptom is absent the diagnosis cannot be made. "Whether or not a diagnosis can be made by the use of occult blood tests when no gross evidences of hemorrhage have been observed is a question to be determined. That such tests should be made in all cases where vomiting is associated with atrophy in young infants is indicated, as it is only in this way that the value of such tests for the early diagnosis of duodenal ulcer can be determined."

Very little can be done in the way of treatment of a condition about which so little is known. In Veeder's opinion about the only indication is to place the infant under the best nutritional conditions, which means breast milk, and it is to this alone that he attributes the improvement in one of his cases. Operation was not deemed advisable in

any of his cases owing to the severe general nutritional disorder of the infants at the time the diagnosis was made. Yet the mortality was 80 per cent. and he admits that if methods are found by which an ulcer can be recognized early surgical treatment offers at least a theoretical possibility. This admission is encouraging, for it took years of educational effort on the part of the surgeon and a high ultimate mortality under medical treatment to convince the internist that gastric and duodenal ulcers in the adult are essentially surgical conditions.

THE BIOLOGICAL ACTION OF THORIUM-X.

THE growing importance of radioactive substances as therapeutic agents imparts considerable interest to recent investigations of their physiological action. Most of the observations along this line have been concerned with the effect of radiant energy upon the skin, and little precise information has been gleaned with respect to the action of this occult agent upon the inner organs. In most of the animal experiments in which the deeper effects of radioactive substances have been studied, doses much larger than the ordinary therapeutic ones have been employed. A. da Silva Mello (*Zeitschrift für klinische Medizin*, Vol. 81, Nos. 3 and 4) has made an experimental study of the biological effect of therapeutic doses of thorium-X, particularly with reference to the blood. The substance was diluted with physiological salt solution and injected under the skin in rabbits.

Among the chief results of this study it was found that thorium-X is capable of producing not only a sudden fatal intoxication, but also a slow one ending fatally after a number of months. The symptoms of the chronic type of intoxication include a progressive and prolonged loss of weight, and a persistent anemia and leucopenia. These symptoms may arise alone or in various combinations. They may also be entirely absent and yet the animal may succumb after a second injection. Neither in the acute nor in the chronic type of poisoning can one attribute the fatal outcome to changes in the hematopoietic organs. Thus, in the acute type of poisoning the elements of the bone-marrow and the lymphatic follicles of the spleen remain largely intact, and there are evidences of regeneration of the cells that have been destroyed. The blood-forming organs may also be subjected to the action of doses exceeding the fatal ones and to the destructive action of the *x*-rays without causing the death of the animal. In the chronic type of thorium poisoning the hematopoietic organs are not responsible for the fatal outcome, as may be shown by the fact that in this type there is a hyperplastic condition of the bone-marrow.

The leucopenia of thorium-X poisoning which has hitherto suggested lesions of the hematopoietic organs is regarded by the author as a concomitant or an accessory symptom. The leucopenia may be most pronounced even when the bone-marrow is markedly hyperplastic. The subordinate significance of this symptom is perceived in the fact that during its presence enormous suppurations may occur or a pneumonia may go on to resolution. The leucopenia may even be absent in severe cases of thorium-X poisoning. Approximately the same facts are true with respect to the erythroblastic system. The hemoglobin may increase and the erythrocytes may regenerate to a degree above the normal in cases of thorium-X poisoning in which there is a pronounced reduction in the body weight and leucocyte count.

With respect to the blood-forming organs there is pointed out a direct contrast between the action of the *x*-rays on the one hand and that of thorium-X on the other. The latter exerts only a slight influence on the lymphoid tissues. The myeloid tissues, on the other hand, are damaged earlier and more intensively. These facts serve partly to explain the variability in the therapeutic effects of thorium-X in one and the same disease.

A NEW PROGNOSTIC SIGN IN PULMONARY TUBERCULOSIS.

THIS sign consists in the degree of reaction of the skin to the application of croton oil, the more intense the reaction the greater being the defensive forces of the body and hence the more favorable the prognosis. A. Campani (*Rivista Critica di Clinica Medica*, November 14, 1914) studied this phenomenon in the course of his experiments to determine the value of fixation abscesses produced by croton oil in the treatment of pulmonary tuberculosis. Fouchier had obtained some degree of success in the treatment of puerperal infection by means of fixation abscesses evoked by the subcutaneous injection of oil of turpentine. Campani attempted to imitate this method in the treatment of pulmonary tuberculosis, using for this purpose local applications of croton oil. Although the results were negative from a therapeutic viewpoint, important observations were made regarding the degree of cutaneous reaction as a prognostic index.

It was found that in normal individuals the inunction of the skin of the arm with a 10 per cent. ointment of croton oil with petrolatum as a base produces a well-marked erythema with the formation of papules and pustules of various sizes and accompanied by itching and sometimes by pain. With the subsidence of the local reaction there are left copper-colored spots that persist for several months. In tuberculous patients there are different degrees of reaction. This is termed negative if there are only a momentary redness and a slight itching. The reaction is slightly positive (+) if there is a pronounced erythema with a few pustules. The reaction is positive (++) if there are many pustules which reappear with each subsequent application of the salve. A highly positive reaction (+++) occurs with a marked swelling of and pain in the arm which, however, do not last longer than a day.

According to Campani if the croton-oil reaction is intense and diffuse, one may anticipate a favorable outcome in any given case of tuberculosis. If, on the other hand, the reaction is negative a rapid evolution of the disease and a fatal termination may be predicted. The significance of the intermediate reactions is difficult to interpret. These suggest

an unfavorable rather than a favorable outcome. The cutaneous reaction apparently serves as an index of the strength of the patient's natural defences.

A Practical Plan for a Holiday.

A somewhat novel idea is being tried out in Bury, England, whereby the busy practitioner can squeeze in a summer vacation of several weeks without loss of money or patients. The scheme is briefly this: A number of medical men residing in the same community have drawn up an agreement whereby each takes his vacation in turn, the other doctors in the agreement caring for his practice in his absence. In order to avoid possible personal antipathies on the part of patients, each doctor selects more than one substitute and before going away gives to his patients a card having on one side: "Dr. ——— requests one of the following (naming the physicians, to attend Mr. ——— until such a date." On the other side of the card are ruled spaces, to record calls. Should the patient have occasion to call in the substituting doctor, he gives him this card, and the doctor notes that and subsequent visits, mailing the original doctor the card upon his return. No pay is received by the substituting doctor, nor does he accept fees, except for obstetrical cases, when he receives one-half. As the arrangement is a mutual or cooperative one, this works out equitably for all concerned. The advantages of this plan are obvious. It provides the practising physician with an assured vacation every year and that, too, without loss. It would seem feasible to try out this plan, with whatever modifications may be necessary, in a number of cities in the United States, and a report on its pragmatic value would no doubt be interesting.

News of the Week.

Committee of American Physicians for the Aid of the Belgian Profession.—The treasurer, Dr. F. F. Simpson, 7048 Jenkins Arcade Bldg., Pittsburgh, Pa., reports the receipt of the following contributions for the week ending June 5, 1915:

Dr. Arthur G. Larkin, New York, N. Y.	$10.00
Dr. John A. Hawkins, Pittsburgh, Pa.	10.00
Medical Society of the Co. of Greene, Catskill, N. Y.	15.00
Wilson County Medical Society, Fredonia, Kansas	15.00
Dr. Robert C. Davis, Johnstown, Pa.	5.00
Dr. Emery Marvel, Atlantic City, N. J.	25.00
Dr. C. J. Hagens, Chicago, Ill.	15.00
Medical Society of the County of Westchester (second contribution) White Plains, N. Y.	2.50
Rockland County Medical Soc., Nyack, N. Y.	28.00
San Luis Valley Medical Soc., Alamosa, Colo.	25.00
Receipts for the week ending June 5th	$150.50
Previously reported receipts	7,008.50
Total receipts	$7,159.00
Previously reported disbursements:	
1,625 Standard boxes of food at $2.20	$3,575.00
1,274 Standard boxes of food at $2.30	2,930.00
213 Standard boxes of food at $2.28	485.64
Total disbursements	6,990.84
Balance	$168.16

Physician Wanted for Relief Work in Montenegro.—The Montenegrin Relief Committee announces that excellent opportunities are open for a physician who would wish to enlist in the relief work in Montenegro. Among the inducements are a material reduction in the expense of transportation and a letter of introduction to the King of Montenegro. Further information may be obtained by addressing Captain A. V. Seferovitch, care of the Montenegrin Relief Committee, 527 Fifth avenue, New York. The secretary of the Committee is Mr. Arnold Wood. The next relief ship sails on June 16.

A New State Medical Law for New Jersey.—This law which goes into effect immediately requires that after July 1, 1919, no person shall be admitted to examination for license unless he has had an academic education consisting of a four years' course of study and a course of one year in a college, during which year he or she has studied either French or German, and also chemistry, physics, and biology. After 1920 a suitable course of two years in a college with the study of either French or German will be required. After July 1, 1916, in addition to the above the applicant for a license must prove that he has served as an interne for at least one year in a hospital approved by the licensing board.

Liberal Construction of Workmen's Compensation Laws.—The Massachusetts Workmen's Compensation Law provides for compensation for "personal injuries arising out of and in the course of" the workman's employment. In a recent issue of *Public Health Reports* there appears an account of an opinion written by Chief Justice Rugg of the Supreme Court of Massachusetts, construing the law in the broadest possible manner, as providing for compensation for workmen acquiring acute or chronic disease as a result of occupation, or in the course of employment, as well as for workmen injured by industrial accidents.

Constitutionality of Law Requiring Tuberculin Testing of all Dairy Cattle.—The Supreme Court of Mississippi has upheld the constitutionality of the ordinance adopted by the Mississippi State Board of Health requiring that "each person, firm, or corporation owning or conducting a dairy in the State of Mississippi, or engaged in the sale of milk and its products" shall have " all cows used in and about the business examined for tuberculosis and other contagious and infectious diseases by some competent veterinarian" to be designated by the local health officer. The ordinance further provides for the condemnation of infected cows, and prohibits the owners of such cows from selling or offering for sale "any milk obtained from any cow, the use of which has been condemned or prohibited, or any cow known to be infected or the milk of which is impure and injurious to the public health."

Death Rate in New York City.—The Health Department reports for the week ending May 29, 1,449 deaths and a rate of 13.02, as against 1,547 deaths and a rate of 14.46 during the corresponding week in 1914, a decrease of 98 in the absolute figures and a rate of 1.44 points, which is equivalent to a decrease in the relative figures of 160 deaths. Scarlet fever, typhoid fever, diphtheria, and croup, diarrheal diseases, organic heart diseases, acute bronchitis, lobar pneumonia, pulmonary tuberculosis, diseases of the nervous system, and deaths from violence all showed considerably decreased mortalities.

The New Columbia Medical School.—The plans of the new buildings of the College of Physicians and Surgeons and of the Affiliated Presbyterian Hospital call for an expenditure of $7,500,000. These plans include the immediate erection of a building for administration; a building to house the medical sciences, the Crocker Cancer Research laboratories, and a school of sanitary science and public health; a building to house the hospital; a building for the Vanderbilt Clinic, to serve also as the out-patient department of the hospital; dormitories for 400 medical students, with dining hall for students and instructors; and a building to house a training school for nurses and to serve as the

nurses' home. The plan also provides space for a possible building for the Sloane Hospital. A considerable part of the area is to be left for future institutes or foundations which may affiliate themselves with the hospital and the university. The plans of the Presbyterian Hospital provide for a building designed to contain 650 beds. It will include the regular services of every general hospital, and in addition eight separate ward services for special genitourinary surgery, for orthopedic surgery, for diseases of the eye, ear, nose, and throat, for diseases of children, for diseases of the nervous system, and for diseases of the skin, and a ward service for every department represented in the Vanderbilt Clinic, as well as seventy-five private rooms. The plans further provide a prearranged scheme for largely increasing the plant.

A Royal Patient.—King Constantine of Greece is reported to have been operated upon for empyema, June 5, by Eiselsberg of Vienna.

To Minimize Auto Accidents at Grade Crossings.—The Long Island Railroad is inaugurating a campaign for this purpose by means of large warning signs and educational advertisements in the newspapers.

James Mackenzie of London, the well-known authority on heart disease, has recently been knighted by the King of England.

Transfer of Boston Quarantine Station.—On June 1 this station was transferred to the Public Health Service of the United States with Dr. Samuel B. Grubbs in charge.

Florida Board of Medical Examiners.—A bill providing for a single board of medical examiners, in place of the three separate boards, has passed the Florida legislature.

The Federal Antinarcotic Law.—Physicians are reminded of the fact that the present license taken out under this law expires on July 1 next and that the tax of one dollar for the renewal of this license for one year should be sent before that date to the local Collector of Internal Revenue. According to a recent ruling from Washington, the words "synthetic substitutes," as used in this law, are held to apply to any artificial substance or preparation which is or may be substituted for cocaine, alpha or beta eucaine, or any of their salts as ordinarily prescribed or used, and not necessarily to a purely synthetic substitute which, chemically, is identically the same as the drug for which it may be so substituted. Further, both the title and Sec. 1 of this law include "opium or coca-leaves or any compound, manufacture, salt, derivative, or preparation thereof," and, under a liberal interpretation of the word "derivative," from a chemical point of view, the several cocaine substitutes would also be clearly included.

Gift for Medical School.—Mrs. Mary Emery has made a gift of $250,000 to go toward a medical school to be operated in connection with the new Cincinnati Hospital. The hospital commission has announced that a similar amount would be raised by the commission to go toward the same purpose. The school will be located near the new hospital and will be under the supervision of the Ohio-Miami Medical College.

Hospital for University of Georgia.—A new hospital erected by the city of Augusta, Ga., at a cost of $500,000, will be turned over to the medical faculty of the University of Georgia. It is erected on the grounds of the medical college.

Dog Muzzling Law Sustained.—The Appellate Division of the Supreme Court on March 29, 1915, unanimously sustained the validity of Section 80-a of the Sanitary Code which prohibits any unmuzzled dog on any public highway or in any public park or place in the city of New York.

The New York Geriatric Society was organized on June 2, 1915, with the following officers: *President*, Dr. Robert Abrahams; *Vice-President*, Dr. Edward P. Swift; *Secretary*, Dr. I. L. Nascher, 103 W. Eigthy-eighth street. This is the first society ever organized for the scientific study of senile conditions; for the study of the causes of ageing and the diseases of advanced life; and for the home and institutional care of the aged. Papers, reports, and other matter dealing with this subject are solicited. There will be monthly meetings, the time and place to be announced in the medical journals.

Society for the Study of Infectious Diseases.—This society has recently been organized in New York City. The active membership is composed of the assistant visiting physicians of the Willard Parker, Riverside, and Kingston Avenue Hospitals, and those who have previously held such positions. The honorary membership is made up of the members of the Medical Board and such others as may be invited by the Society. The first meeting, which was held at the Willard Parker Hospital on May 4, was devoted to the subject of arthritis complicating scarlet fever.

The New Willard Parker Staff House.—A contract for the erection of a Medical Staff House and Nurses' Home for the Willard Parker Hospital has been awarded and the work has been started. This building, covering an area of 100 by 83 feet, will be located on the south side of 16th Street, just west of Avenue D. It will be of concrete fireproof construction, seven stories high above the basement, and will furnish quarters for thirty-five doctors and one hundred and fifteen nurses, each group having separate entrance, halls, stairs, dining room, etc., complete. The basement will contain a swimming pool, 15 feet by 37 feet 6 inches, lined with glazed tile, nine individual dressing rooms, showers, douche, and toilet. A gymnasium for nurses occupies the south end of the seventh floor, west wing.

Charitable Bequest.—By the will of the late Martha Moore of Philadelphia the sum of $1000 is bequeathed to the Methodist Hospital.

Medical Society Elections.—The Fulton County (Ky.) Medical Association at its annual meeting held in Fulton May 23 elected the following officers: *President*, Dr. John Naylor of Cayce; *Vice-President*, Dr. J. B. Paschall of Fulton; *Secretary and Treasurer*, Dr. Seldon Cohn of Fulton; *Delegate to the State Society*, Dr. H. E. Prather of Hickman; *Alternate*, Dr. George Crafton of Fulton.

The Frisco System Medical Association at its annual meeting held in Springfield, Mo., May 23 and 24, elected the following officers: *President*, Dr. W. Y. Yates of Fayetteville, Ark.; *Vice-Presidents*, Dr. W. B. Burns of Memphis, Tenn., Dr. O. S. Harrison of Kenett, Mo.; *Secretary and Treasurer*, R. A. Woolsey of St. Louis; *Member of Executive Committee*, Dr. Elmer E. Liggett of Oswego, Kan. Memphis was chosen for next year's convention.

The Essex North District (Mass.) Medical Society, at its annual meeting in Lawrence, May 5, elected the following officers: *President*, Dr. Victor A. Reed of Lawrence; *Vice-President*, Dr. F. B. Pierce of Haverhill; *Secretary and Treasurer*, Dr. J. F. Burnham of Lawrence; *Auditor*, Dr. F. H. Coffins of Haverhill; *Corresponding Secretary*, Dr.

T. M. Stone of Haverhill. *Censors*, Drs. T. R. Healy and A. N. Little of Newburyport; J. J. Sullvan, F. D. McAllister, G. E. Kurth of Lawrence; H. L. Conner, F. B. Pierce, J. E. Bryant and H. Donohue of Haverhill; E. H. Noyes and F. W. Snow of Newburyport; H. P. Robinson of Amesbury, and R. V. Baketel of Methuen. *Councillor on Trials*, Dr. J. F. Croston of Haverhill; *Nominating Councillor*, F. W. Snow of Newburyport; *All Nominating Councillor*, R. V. Baketel of Methuen.

The Wisconsin Surgical Association in its annual meeting held in Milwaukee, May 5, elected the following officers: *President*, Dr. F. G. Connell of Oshkosh; *Vice-Presidents*, Dr. C. H. Levings of Milwaukee; Dr. J. M. Dodd of Ashland; Dr. Carl Doege of Marshfield; Dr. D. J. Hayes of Milwaukee; *Secretary-Treasurer*, Dr. Daniel Hopkinson of Milwaukee; *Regents*, Dr. W. C. F. Witte and Dr. C. H. Levings of Milwaukee.

The Central Illinois Medical Society at its annual meeting in Taylorsville, Feb. 16 to 18, elected the following officers: *President*, Dr. H. K. Fink of Hillsboro; *Vice-President*, Dr. G. G. Garrison of Heyworth; *Secretary*, Dr. L. T. Lundy of Edinburg; *Treasurer*, Dr. H. B. Singer of Nokomis; *Librarian*, Dr. W. H. Scherer of Raymond. The next annual meeting will be in Hillsboro.

The Southwest Missouri Medical Society at its annual meeting in Springfield, April 30, elected the following officers: *President*, Dr. J. W. Love of Springfield; *Vice-Presidents*, Dr. J. H. Elliott of West Plains, and Dr. M. C. Stone of Springfield; *Treasurer*, Dr. Lee Cox of Springfield; *Secretary*, Dr. H. S. Hill of Springfield.

The Norfolk District (Mass.) Medical Society at its annual meeting in Boston, May 11, elected the following officers: *President*, Dr. V. M. Pierce of Milton; *Vice-President*, Dr. T. F. Greene of Roxbury; *Secretary*, Dr. Brandford Kent of Dorchester; *Treasurer*, Dr. G. W. Kaan of Brookline; *Commissioner of Trials*, Dr. A. P. Perry of Jamaica Plain.

The Kansas State Medical Society at its annual meeting in Kansas City, May 6, elected the following officers: *President*, Dr. O. D. Walker of Salina; *Vice-Presidents*, Drs. C. W. Jones of Olathe; B. F. Chilcott of Osborne, and J. R. Scott of Newton; *Secretary*, Dr. C. S. Huffman of Columbus; *Treasurer*, Dr. L. H. Munn of Topeka; *Delegates* to the A. M. A. meeting, Drs. W. F. Sawhill of Concordia, and M. F. Jarrell of Fort Scott. The meeting next year will be held in Topeka.

Obituary Notes.—Dr. Samuel Baldwin Ward, for many years dean and professor of medicine of the Albany Medical College, died at his home in Albany, N. Y., on June 3, after a long illness, aged 73 years. Dr. Ward was graduated from Columbia College in 1861, and from the Georgetown University School of Medicine, Washington, in 1864, having served as a medical cadet in the Union Army during the Civil War. He was for several years professor of anatomy and surgery in the Women's Medical College of the New York Infirmary, going to Albany in 1876. He had served as attending physician to the Albany Hospital and consulting physician to the South End Dispensary, and was a member of the Medical Society of the State of New York, the Albany County Medical Society, the Association of American Physicians, and the American Medical Association.

Dr. Louis F. Bischof of New York, a graduate of the New York University Medical College, New York, in 1885, and a member of the New York State and County Medical Societies, died at his home on May 23, aged 52 years.

Dr. John N. Frank of St. Louis, Mo., a graduate of the Washington University Medical School, St. Louis, in 1869, and for twelve years coroner of St. Louis, died at his home, after a long illness, on May 4, aged 66 years.

Dr. Frank Eugene Baker of Woodford, Vt., a graduate of the Long Island College Hospital, Brooklyn, in 1891, died in North Adams, Mass., on May 8, aged 45 years.

Dr. Bernard G. Maercklein of Milwaukee, Wis., a graduate of the University of Pennsylvania, Department of Medicine, Philadelphia, in 1887, formerly professor of oral surgery in the Milwaukee Medical College, of which he was one of the founders, and later professor of the same subject in the Marquette University School of Medicine, and a member of the State Medical Society of Wisconsin and the Milwaukee County Medical Society, died after a long illness, on April 30, aged 67 years.

Dr. Frederick S. Coolidge, formerly of Chicago and of Pittsfield, Mass., a graduate of the Harvard University Medical School, Boston, in 1891, a member of the American Medical Association and of the American Orthopedic Association, one of the founders of the Anti-Tuberculosis Association of Pittsfield and of the orthopedic clinic of the House of Mercy, and well known as an orthopedic surgeon, died at his home in New York, after a long illness, from tuberculosis, on May 15, aged 49 years.

Dr. John A. Lee of Framingham, Mass., a graduate of the Tufts College Medical School, Boston, in 1911, died at the Framingham Hospital, on May 5, aged 28 years.

Dr. Horace Morgan Fritz died at Quincy, Pa., on May 12, at the age of 60 years. He was graduated from Jefferson Medical College in the class of 1879.

Dr. William J. Armstrong died at Kane, Pa., on May 13, at the age of 62 years. He was graduated from Bellevue Hospital Medical College in the class of 1883.

Dr. Albert Joseph Roberts of Bridgeport, Conn., a graduate of the Harvard University Medical School, Boston, in 1902, and a member of the Connecticut State and Fairfield County Medical Societies, died at his home, after a short illness, on May 12, aged 41 years.

Dr. Henry B. Roberts of Cordele, Ga., a graduate of the Atlanta Medical College in 1882, and a member of the Medical Association of Georgia and the South Georgia Medical Society, died at his home from Bright's disease on May 8, aged 63 years.

Dr. William F. Goldin of Draketown, Ga., a graduate of the Atlanta Medical College in 1877, and formerly State Senator, died at his home on May 8, aged 65 years.

Dr. George Gustave Lempe of Albany, N. Y., a graduate of the Albany Medical College in 1888, attending surgeon to the Albany Hospital, and a member of the American Medical Association, the American Association of Anatomists, the Association of Military Surgeons of the United States, and the New York State and Albany County Medical Societies, died at his home on May 17, aged 49 years.

Dr. Amos Walker Barber of Cheyenne, Wyo., formerly governor of Wyoming and president of the Wyoming State Medical Society, a graduate of the University of Pennsylvania, Medical Department, in 1883, and a member of the State and Laramie Coun-

ty Medical Societies, died at Rochester, Minn., on May 18, aged 55 years.

Dr. Henry W. Muller of New York, a graduate of the New York University Medical College in 1898, and a member of the American Medical Association and the New York State and County Medical Societies, died at his home on May 21, aged 44 years.

Dr. Alfred C. Clark died at Sunbury, Pa., on May 17 at the age of 70 years. He was graduated from Jefferson Medical College in the class of 1869.

Dr. Gilbert L. Parker died at Philadelphia on May 19 at the age of 83 years. During the Civil War he organized a company and he served in the Twenty-eighth Pennsylvania Volunteers. He was breveted lieutenant-colonel for distinguished services on the battlefield. He was graduated from Jefferson Medical College in the class of 1874.

Dr. Fayette H. Peck of Utica, N. Y., a graduate of the New York University Medical College, New York, in 1881, visiting surgeon to St. Luke's Hospital, Utica, and a member of the American Medical Association and the New York State and Oneida County Medical Societies, died at his home on May 24, aged 59 years.

Dr. Hewlett Whitty Oakley of Portersville, Cal., a graduate of the University and Bellevue Hospital Medical College, New York, in 1904, and a member of the American Medical Association, the Medical Society of the State of California, and the Tulare County Medical Society, died at his home on May 23, aged 35 years.

Dr. Henry Bak of Atlanta, Ga., a graduate of the University of Vienna in 1872, professor of medicine and pediatrics in the Southern College of Medicine and Surgery, Atlanta, and formerly a surgeon in the Austrian army, died at a hospital in Chicago, on May 25, aged 68 years.

Dr. Thomas H. Maxedon of Vincennes, Ind., a graduate of the Hospital College of Medicine, Louisville, Ky., in 1897, and a member of the American Medical Association, the Indiana State Medical Association, and the Knox County Medical Society, died suddenly from cerebral hemorrhage at his home on May 19, aged 53 years.

Dr. Lewis C. S. Turner of Colfax, Ia., a graduate of the College of Physicians and Surgeons of Keokuk, Ia., in 1882, and a member of the Iowa State and Jasper County Medical Societies, died at his home, after a long illness, on May 18, aged 61 years.

Dr. Michael F. Gavin of Boston, Mass., a graduate of the Harvard University Medical School in 1868, formerly visiting surgeon to the Carney Hospital and to the Boston City Hospital, consulting surgeon to St. Elizabeth's Hospital, and professor of clinical surgery at the Boston Polyclinic, and a member of the American Medical Association, the Massachusetts and Suffolk District Medical Societies, the British Medical Association, the Royal College of Surgeons, and the Boston Society for Medical Improvement, died at his home after a long illness on May 20, aged 72 years.

Dr. Guilford D. Yokom of St. Joseph, Mo., a graduate of the Chicago Homeopathic Medical College in 1879, and a member of the Missouri State Medical Association, and the St. Joseph-Buchanan-Andrew Counties Medical Societies, died on May 19, aged 67 years.

Dr. Isaac T. Rand of New Iberia, La., a graduate of the Tulane University of Louisiana, School of Medicine, New Orleans, in 1886, and a member of the Louisiana State Medical Society, died at his home on May 14, aged 49 years.

Dr. Stephen Townsend of Columbus, O., a graduate of the Cleveland College of Physicians and Surgeons, Cleveland, O., in 1891, died, after a brief illness, from apoplexy, on May 15, aged 68 years.

Dr. John Franklin Marshall of Brooklyn, N. Y., a graduate of the New York University Medical College, New York, in 1890, died at his home, from pneumonia, on May 31, aged 50 years.

Dr. William Monroe Carling of Battle Creek, Mich., a graduate of the Medico-Chirurgical College of Philadelphia in 1897, and a member of the Michigan State and Calhoun County Medical Societies, and the Southwestern Michigan Triological Society, died suddenly, while golfing, on May 30, aged 42 years.

Dr. John Rice Eldridge of Berkeley, Cal., a graduate of the Cooper Medical College, San Francisco, in 1894, died recently at his home, aged 51 years.

Dr. William Marion Forman of Louisville, Ky., a graduate of the University of Louisville, Medical Department, in 1877, died at his home, from heart disease, on May 24, aged 65 years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

IN PARLIAMENT, ARMY SURGEONS REINFORCED—LEUCEMIA, DISCUSSION—ROYAL SOCIETY OF MEDICINE, DEFORMITIES OF TIBIÆ—SELT-MUTILATION.

London, May 21, 1915.

In the House of Commons it has been stated officially that 7,027 doctors are at present serving in the army, including army medical service and R. A. M. C. 1,008, retired re-employed R. A. M. C. officers, 174; Special Reserve R. A. M. C. officers, 623; temporarily commissioned, 3,100; Territorial Force R. A. M. C., 2,122. More than 5,000 medical men had offered their services and 3,100 had been appointed. There was no scarcity at the front or at home so far, but further numbers would be called for. As consultants the following surgeons are employed at the front: Sir G. H. Makins, Sir A. A. Bowlby, Mr. F. F. Burghard, Mr. W. T. Lister, Mr. H. M. W. Gray. Also the following physicians: Sir W. P. Herringham, Sir A. E. Wright, Sir J. R. Bradford, and Sir B. Dawson. These officers received pay as colonels of the army medical service, and the Government had found no difficulty in obtaining eminent men for the work at home or abroad.

An agreement had been made with Germany for women or children and certain professionals to be allowed to go home, but the Foreign Secretary stated that in some cases Germany had retained some without the slightest justification, and negotiations are proceeding for the release of military medical officers.

After the war leucemia has of late been the topic most ready to intrude into every conversation—between medical men, of course, understood—and some of the unexpected remarks are curious. Take an example or two: Dr. Senior—you give a new name to anemia, but you do not thereby tell us anything about the condition. Dr. Junior—on the contrary, I do not consider the two names synonymous. Virchow proposed leukhæmia and Hughes Bennett, to be more exact, suggested leucocythemia, thus limiting the whiteness to cells, and so you mark progress; and leukhemia now is defined properly as a

blood disease associated primarily with changes in the spleen and bone-marrow or in the lymphatic glands. Dr. Senior—well, then, when the spleen is at fault, as it mostly is, you might be content with splenic leucocythemia, which would be reasonably descriptive, both clinically and etymologically. At the same time observe you will meet with cases that seem to originate in or be associated with other tissues, *e. g.* the bowels when you get what you may call intestinal leucemia—ask our listener who has not said a word. Dr. Silent—I prefer to hear others, but I agree with the last speaker and have noticed or heard of other varieties, such as hepatic, aplastic, myelocytic, pseudo, and mixed leucemia. In fact I have sometimes doubted whether we are entitled to call it a blood disease if so great a variety of tissues may set it up. The etymology does not concern one much, for we doctors are not particularly strong in classics and the few who are Greek scholars are tolerant of those who are not. However, I may say that both names are faulty—the *an* of the one is a private and the *leuc* of the other white. Strictly, neither can apply to the blood.

The foregoing notes of a casual chat—a specimen of many—may be followed by a report of a more formal discussion on the subject at the Royal Society of Medicine. This was opened on the 27th inst. by Dr. A. J. Hall with notes of a case of acute lymphatic leucemia ending in recovery. A man of 26 consulted his attendant in March, 1911, for swelling on right side of neck, painless but increasing. No cause was detected, nothing abnormal except slight albuminuria. Six days later seen by Dr. Hall, who felt a large glandular mass on the right side. There were also solitary enlarged glands on both sides of the neck, in both axillæ and in both groins. The spleen was felt about three-quarters of an inch below costal margin. He did not look anemic, had no sore throat and no hemorrhages, his teeth were good. Blood examination showed: hemoglobin, 96 per cent.; red corpuscles, 5,400,000; leucocytes, 32,000; lymphocytes, 96 per cent.; polymorphonuclears, 4 per cent. No eosinophiles and no evident changes in red cells. Evening temperature, 101° F. Provisional diagnosis, "acute lymphatic leucemia," was treated with liq.-arsenicalis. Two days later patient felt some pain in right side of throat, vomiting soon followed, but the glands were smaller. A differential count gave large lymphocytes 85.2 and small 4.4 per cent., polymorphonuclears 10.4 per cent. No eosinophiles in counting 300 cells. The right tonsil became more painful and covered with an exudate. The spleen extended lower. Improvement then occurred and continued steadily until he was well and able to go shooting in August. Dr. Hall thought the provisional diagnosis was incorrect and the case belonged to the category of lymphocytosis associated with cervical and general adenitis, to which attention has lately been drawn and such cases rendered prognosis doubtful. Dr. Hall related further the following cases:

1. Chronic myelemia treated by *x*-rays with complete recovery after a severe exacerbation in a man of 34 who did his full work as a colliery electrician for nearly three years, after which another severe exacerbation lasted three months with enlarged liver and ascites, some hemorrhages, and impaired vision. Under *x*-rays recovery again, and he did full work for five months, when a third attack came on which proved fatal in five months. 2. Chronic myelemia treated by *x*-rays restored to full health for about six months. He died later from a pneumonic attack. 3. Chronic myelemia in a woman in whom a greatly enlarged spleen had become dislocated, forming a tumor, which led to an exploratory operation.

Dr. Parkes Weber read a full report of a case of long duration though, looking back on it, he doubted if the symptoms which from time to time drove the patient (a woman) to seek advice depended chiefly on the blood condition. A real improvement in 1909 might have been associated with reductions of the spleen under radium and atoxyl. In so great enlargement as in this case lymphatic leucemia was unusual and perhaps absence of anemia showed the red bone marrow was able to retain its activity. He believed that in all cases of splenomegaly, apart from leucemia, the tendency was towards a leucopenic blood count rather than excess of white cells. Chronic leucemia (more or less quiescent) was often indicative of splenomegaly with excess of white cells. Sir William Osler did not remember a case with a lymphocyte count above 90 per cent. Dr. Galloway had seen many cases treated by *x*-rays. In one the patient was extremely ill, but lived five years. Dr. Ironside Bruce also had good effects from *x*-rays, improvement being great, but at present only temporary. Dr. Weber thought no case of leucemia had ever been cured, and Dr. Hall's case was probably lymphocytosis.

At the Royal Society of Medicine last week Mr. Kellock showed in the clinical section a lad of 13 who was ten years previously operated on for deformity of both tibiæ, which were very much bowed outwards and forwards; there was a separation of 3 inches of the inner condyles of the femora when the malleoli were touching. Open osteotomy of the tibiæ was performed, the patient being then as seen from above history, 3 years of age; the fibulæ were fractured and the legs put up in plaster of Paris splints. At the meeting the legs were seen to be quite straight, and in the skiagram there was practically no indication of the sites of the osteotomies, the lines of the bones being normal. Later the boy was again in hospital for abdominal trouble, thought to be probably tuberculous peritonitis.

Mr. Kellock also read a short paper on a form of self-mutilation of young boys in which he mentioned a case of a boy of 8, from whom he removed a metal which surrounded the glans and had ulcerated through the floor of the urethra. In another case cotton had been twisted round the base of the glans and in three others hair around the penis just behind the glans. One, æt. 5, was typical of the three; the glans was almost completely separated, being attacked by an isthmus only one-eighth of an inch thick and it was much discolored, and just behind the corona was a sulcus covered by epithelium. Using a crochet needle, under an anesthetic, Mr. Kellock found a hair twisted three times around the narrow isthmus. The two other cases were practically the same. Plastic operation, after removing the hair, was done with difficulty. In two he had been able to reconstruct the urethra, but the other was followed by sloughing off of the glans.

The Ferments of the Blood.—G. Satta finds after the separation of the globulin and albumin fractions of the blood serum that the ferments tributerinase, amylase, and glycyl l. tyrosinase reside solely in the albumin fraction.—*Archivio per le Scienze Mediche.*

Progress of Medical Science.

6. Tuberculosis of the Throat. A. C. Getchell.

2. Hospital Efficiency and the Efficiency Expert.—F. B. Gilbreth points out that the hospital is subject to all the laws and processes of obtaining efficiency in the manufacturing establishment. A fundamental requirement is the accurate measurement of aims and methods. The survey principle should be applied; there should be a record of *what* is being done, and *how* and *why* it is being done. The first step in all improvement is an accurate record of present practice.

3. Hospital Efficiency and the Hospital Surgeon.—R. L. Dickinson states that the following are capable of standardization: the training and qualifications of the workmen and heads of departments and even the trustees; the tools and equipment; the organization of the workshops; and the procedure. There are five inefficiencies in professional work: (1) Lack of time given by the staff. The remedy includes a requirement of fixed hours and quality of work for salary; selection and promotion for merit; a continuous service; assistants with some salary and in sufficient numbers; a senior resident on salary. (2) Lack of organization. The remedy comprises single headed departments; small committees held to strict accountability; an understudy for every position; the associate in full charge two months of each year; long time team-work in operating room; short time internes to do only minor surgery. (3) Lack of instruction. There should be definite methods and times of teaching and drilling younger men. (4) Lack of inspection. There is no check on the quality of work or end results. (5) Lack of publicity. There are no bulletined errors and no available comparisons. The author suggests a special form of report on the efficiency of each member of the professional staff. This report details the quantity and the quality of work; personality, progressiveness and executive ability; teaching; and inspections. The following committees are necessary: an efficiency committee; professional staff committees on house staff, operating room, ward, histories, and dispensary; and planning committees on order of work instruction, and discipline. There should be a Central Board on Standards, whose function it should be to collect information and sift it, to allot the parts of the great problems for investigation, to furnish means for some part of the necessary research, to publish the results, and in general to serve as a board of control. Experiment stations should be established in a variety of locations and institutions. There should be a central library with branches and the utmost facility for loaning books. A museum of standards should be established.

5. The Discharged Sanatorium Patient.—J. B. Hawes, 2d, concludes that every tuberculous patient at some time or other needs sanatorium treatment. The doctor's responsibility for his patient does not end as soon as he has safely conducted him within the doors of a sanatorium or other institution. The important period in the treatment of the average case of pulmonary tuberculosis is after the patient has left the sanatorium. The medical profession, either by means of dispensaries or other similar agencies, or in their private practice, must seek out their discharged sanatorium patients and see that they are under proper supervision and control. Every physician should play a part in a broad educational campaign to impress upon the public the need of such supervision and control.

2. The New Human Species.—D. D. Ashley applies this term to the digitigrade individual or toe-walker, the product of fashion and of the shoemaker. Persistent digitigrade progression means weight bearing on the distal extremities of the metatarsal bones, with the phalanges projected upward at a sharp angle instead of extending forward. By continued stretching of the capsular ligaments, the sensitive synovial ends of the bones are uncovered and exposed to pressure. In many cases the joint becomes permanently, partially, or totally luxated or dislocated, resulting in hammer toes or flexed toes of mild or severe degree, with corns on the toes and callosities in the anterior metatarsal arch (metatarsalgia, Morton's disease) due to the crushing and thinning of the tissues and the giving way of the anterior arch, resulting in a broadening and thickening of the anterior part of the foot, with mild or severe hallux valgus, bunions, overriding toes, clubbed toes, hallux rigidus or stiff great toe. The *x*-ray shows a thinned bone cortex, increased cancellous tissue, a dumbbell atrophy of the proximal phalanx, distorted joint surfaces and bent bones. The great mass of muscles on the plantar surface—five layers of plantar flexors built into the arch—are almost functionless. Withered by disuse, crushed by braces and high, unyielding arches built in the shoes, we have seemingly lost track of these muscles in our mad scramble to brace, prop, and support the foot while walking on our toes. There is always a loss of the muscular control which is necessary to an elastic progression, ability to maintain an upright position and a good carriage, and strength to succeed in this strenuous life. The entire anatomy of the part is affected. Weak ankles, loss of balance, fallen longitudinal arch, weak foot, strained foot, sprained foot, sensitive, painful foot, flat foot, rigid foot, elongated foot, pronated foot, abducted foot, and valgus foot are some of the terms designating the ills one bears and the price one pays for unphysiological walking and standing. These conditions are accompanied by swollen, puffy ankles, with referred pains in calf, knee, thigh, and back. Frequently there are severe intermittent cramps, preceded by numbness of the toes and a burning sensation referred to the anterior foot.

9. Septic Conditions in the Abdomen.—A. M. Willis employs a modified Ochsner treatment for practically all infections of the abdominal cavity, and the results obtained by it are uniformly good. Peristalsis and unnecessary handling, two important factors in disseminating pus, are minimized. General peritonitis does not develop when the delay method is properly conducted. A liver abscess or a general septicemia may appear during the treatment, but this is just as likely to happen when an operation is performed in the face of a spreading peritonitis. The limitation of peristalsis is the keynote of the Ochsner treatment, and is accomplished by body and bowel rest and by heroic doses of mor-

phine. In giving morphine we should remember that nausea, gas, and vomiting, three troublesome symptoms of acute abdominal conditions, are also symptoms of morphinism; we should, therefore, regulate our doses of morphine as accurately as possible; cessation of pain and contraction of the pupils are perhaps the best indicators of morphine effect. In order to bring about suitable drainage, three factors have to be considered, viz.: (1) Gravity, (2) capillary action, and (3) siphon action. The best way to empty an abscess is to throw the pus in direct contact with the line of incision—and not away from it, as is done when the patient is placed in a sitting position. In an appendicular abscess the patient should not be elevated, especially if the pus barriers have been broken down at operation and one can never say with any degree of certainty when such an occurrence has taken place—because it is useless and harmful to throw the pus in the pelvis by putting the patient in the sitting posture. The same statement applies to abscesses situated about the gall bladder or liver, for in Fowler's position the pus is liable to gravitate and spread the infection. In abscesses not situated in the pelvis, the patient should not be elevated, but should be turned toward the affected side, and, once or twice a day, should be turned over on the face so as to throw the pus against the line of incision. In abscesses in the pelvis, the Fowler position should be employed, for here one strives to limit the infection by this posture. In general peritonitis the object of the Fowler position is not so much to avoid the diaphragm as to collect the pus in the pelvis. A well placed drain, along with turning the patient on his face, and elevating the foot of the bed for ten minute periods twice daily, will aid in clearing the pelvis of the accumulated pus. There is one point in drainage that deserves special emphasis, and that is, the drain should occupy the most dependent part of the abscess.

2. Hypertonic Solution in Salvarsan Anuria.—R. T. Woodyatt reports the case of a man, aged forty-five, who had an aneurysm of the thoracic aorta and who received one gram of salvarsan within a week. Symptoms first appeared after a characteristic delay and then included fever, albuminuria and urinary suppression, nausea, vomiting, headache, delirium, and an erythematous rash. This case is recorded as one of a salvarsan reaction sufficiently serious to occasion grave concern, in which a sharp turn for the better followed by ultimate recovery took place within a few hours after the administration by bowel of an alkaline hypertonic solution (Fischer's solution) with no other therapy. An isolated experience of this sort is considered as suggestive that a suitable application of the same general therapeutic principles might prove of value in intoxications of the type described.

3. Altitude and Blood Pressure.—F. C. Smith states that the effect of altitude on blood pressure does not appear to be great. The lowering effect of tuberculosis on blood pressure in uncomplicated active tuberculosis is well known, and a tabulated statement of the result as regards hemoptysis of various degrees on forty-three patients is given, but nothing is found to support the contention that hemoptysis depends on high systolic pressure. It seems extremely doubtful whether moderate altitude has any pronounced effect on tuberculosis, except possibly in patients whose circulatory apparatus is unable to accommodate itself to the increased strain put on it.

4. Infections with Hemoglobinophilic Bacteria.—D. J. Davis notes that the hemoglobinophilic bacteria may be divided into two general groups: (1) those of the Pfeiffer-bacillus type, all of which reveal the phenomenon of symbiosis and are very commonly found in infectious diseases; (2) a far more heterogeneous group which includes the organism described by Friedberger, the bacillus found by myself and by Koch in urinary and uterus infections, the bacillus found in the pus of the shoulder abscess previously referred to, and also such organisms as have been described by Moon and some others. The first group is a very definite one, the members of which are closely related; indeed, usually practically identical. The second group comprises bacteria very different in character and remotely related to each other, having in common little more perhaps than the hemoglobinophilic property. Compared with the bacilli of the first group they are rare. The hemophilic bacilli of Pfeiffer's type are of primary importance as secondary invaders in many infectious diseases, especially those involving the respiratory tract. As such, they are not harmless parasites, as has been shown by animal experimentation. In this respect they are about as common and often, perhaps, as important as such organisms as streptococci and pneumococci. That they may be highly virulent at times and the cause of serious primary infections, is clearly shown in the not uncommon cases of purulent meningitis caused by these organisms. Whether or not Pfeiffer's bacillus was the cause of the pandemic of influenza of 1889-1890, or is ever the cause of epidemics of influenza, is still a doubtful question. Epidemics of clinical influenza occurring in recent years have been caused by a variety of organisms, including streptococci, pneumococci, *Micrococcus catarrhalis* and possibly other varieties.

6. Hunger in Infants.—H. Ginsberg, I. Tumpowsky, and A. J. Carlson find that the infant stomach shows feeble tonus contractions of the fundal end one hour after nursing, and as it discharges its contents these gradually increase in frequency and intensity until from the end of two and one-half to three hours they become transformed into vigorous hunger contractions. The minimum was two hours and the maximum three hours. The hunger contractions of the empty stomach are modified tonus waves of the fundus, as shown by Rogers and Hart. In the normal case their presence is probably evidence that the stomach is in proper condition to receive food, and the normal interval between feedings is two and one-half to three hours.

10. Open Treatment of Infected Wounds.—F. G. Dyas concludes that the advance made in the treatment of old suppurative wounds has not been in keeping with the advances made in other departments of surgery. The treatment of suppurating areas by voluminous dressings, either sterile or antiseptic, macerates and devitalizes the tissues, fosters the development of the pathogenic flora, and does not assist in the repair of the

tissue. It is always of advantage, when possible, to convert a moist into a dry type of gangrene. Therefore, the desiccating influence on the wound of the atmospheric air, in the absence of moist coverings of any sort, tends to attenuate infecting organisms. The method is safe, economical, and is in keeping with nature's own processes as observed in the lower animals. The patient's period of convalescence is shortened and he absolutely suffers no pain. In the author's experience, both in the treatment of wounds and of burns, the danger of contamination from the atmospheric air is negligible. The addition of plenty of sunshine would be a valuable asset, but is not readily obtainable.

13. Fullers' Earth and Its Antidotal Value for Alkaloids.—B. Fantus states that alkaloidal fullers' earth compounds do not act on the stomach, but are gradually dissociated in the intestine, producing a delayed and milder general action. Fullers' earth has antidotal value in morphine, cocaine, nicotine, and ipecac poisoning. It has less value in strychnine and in aconitine poisoning, though even in these conditions it is capable of saving life when combined with sodium dihydrogen phosphate. In colchicine poisoning it is of little value. The power of adsorbing alkaloids is strongly developed in some fullers' earths and very feebly in others. The adsorptive value of commercial fullers' earths should be stated by the dealers, and pharmacists should demand specimens of high activity. Lloyd's reagent possesses this power to the highest degree. Fullers' earth is not synonymous with kaolin, as the United States Dispensatory and the National Dispensatory would lead one to infer. It is a substance with markedly different properties.

1. Tonsillar Infections.—F. C. Pybus, in this the second installment of the Hunterian Lecture, after showing the rôle of the streptococcus in rheumatism, chorea, etc., and the importance of tonsillar infection with the pneumococcus, diphtheria bacillus, and other microorganisms, discusses the treatment of tonsillar infection. If the symptoms are mainly or entirely mechanical, and fail to subside in three months after removal of any source of infection, partial removal may suffice. Tonsillotomy, however, has this disadvantage —the basal portion of the tonsil may enlarge and again cause symptoms. In addition to this many hypertrophied tonsils, so far as can be ascertained on inspection, do not appear to be grossly infected. In those cases which are grossly infected the basal portion, often the most diseased, is left behind and may commence to give trouble, especially if some of the lacunæ become partially or entirely sealed up in the process of healing. When infective symptoms predominate in the tonsil itself, such as acute tonsillitis or chronic lacunæ infection, or when the tonsils are in addition enlarged, any source of infection must be removed, especially carious teeth. Nasal breathing must be re-established, and the case watched to see the effect of the treatment. Where the tonsil is too severely affected to be capable of recovery, as judged by the recurrence of symptoms and the failure of the above measures, then total removal is indicated. Enucleation of the tonsil must necessarily prevent tonsillitis, and while it does not entirely prevent pharyngitis such attacks are usually materially lessened in frequency. When repeated quinsies have occurred further attacks may be prevented by removing the source of the infection, the tonsil. For lymphatic gland infections, where tuberculosis is suspected tonsillectomy is indicated; the course of the glandular enlargement determines whether this also may require operation. In pyogenic infections of the glands the tonsil must be dealt with when the acute lymphadenitis has subsided or been operated on if suppuration has supervened. Chronic glandular enlargement of the mild or moderate degree is so frequently met with in hypertrophied tonsils that when the tonsil recovers its normal character the glands subside also. It should be a rule that no tonsil should be removed when acutely inflamed. For more distant infections, when the tonsil is suspected of being the focus, removal is indicated when the general condition is satisfactory. In all these cases total removal is the operation of choice. It presents no greater danger than incomplete removal and can be readily accomplished by the guillotine alone. While these methods directed to the individual are of great importance there is no doubt that prevention of tonsil infection should be one chief aim. This is to be obtained by the advance of hygiene, personal, in the home and school. The maintenance of nasal respiration, the prevention of dental caries, and the proper supply of food in sufficient quality and quantity will greatly diminish the prevalence of this condition. The provision of a cleaner air supply and the prevention of infection by milk are measures needing attention. When that delicate balance between health and infection is upset and the tonsil, a useful organ, becomes diseased and incapable of recovery, a timely removal of this focus may prevent more grave illness and disability. The question of infection of the tonsil and from the tonsil is not to be summed up in some form of operative procedure, but by the attention to the numerous measures I have tried to indicate.

7. Cerebrospinal Fever and the Sphenoidal Sinus.—D. Embleton and E. H. Peters believe that sphenoidal empyema is associated with cerebrospinal fever in a causal manner. Cerebrospinal fever is a meningitis due to organisms entering the meninges from the sphenoidal sinus by way of the lymphatics. Adults are less susceptible owing to a diminished tendency to sphenoidal empyema, as they are not prone to excessive swelling of the mucous membrane and so to closure of the ostia, as is seen in adolescents. It may be advisable to open the sphenoidal sinus in all cases of cerebrospinal meningitis; it is certainly advisable to treat the nasopharynx on the lines used for the acute carrier. The authors make a plea for nasal hygiene in the case of recruits.

6. The Admission of Men with Glasses into the Army. A. A. Bradburne.

1. The Toxemia of Later Pregnancy.—Sir John Byers points out that the eliminative treatment of eclampsia aims (1) at the prevention of the formation of any more toxins; (2) at the elimination of the toxins which are already circulating in the system; (3) at the facilitating of labor at the proper time, if it should come on naturally, no induction of labor being allowed; and (4) at the careful treatment of special conditions, such as

heart failure, obstruction of the larynx, etc. This plan of treatment has been called "the Rotunda" method, because it was begun, slowly evolved—step by step—and brought to its present state in that institution. Stroganoff's method—which differs from that of Zweifel and Lichenstein in that no free bleeding is used—is based largely on the same lines as that employed at the Rotunda clinic, with the following additions and alterations: He tries to avoid all external irritation; hence, the patient is kept in a quiet darkened room; no one is admitted except the doctor and the nurse; everything is done silently, and without fuss or noise. If any examination has to be made—external or internal (only if necessary)—if the catheter has to be used, or a hypodermic of morphine has to be given, the patient is allowed to inhale twenty to thirty drops of chloroform. The fits are controlled by a combination of morphine and chloral (giving the latter by the mouth or by the rectum). Labor is assisted but not forced. The vital processes are to be watched carefully and to be stimulated when necessary. For the respiration, pure warm air is to be used with oxygen after the fits; and the patient is to be kept on her side and careful cleansing of the throat and nose is to be done. For the heart, digitalis and stimulants are to be employed if it gets weakened and milk and saline infusion may be given by the mouth or rectum. For the kidney and skin the best remedies, according to Stroganoff, are warmth and saline infusion. The last statistics show 900 cases reported by Stroganoff with a 7 per cent. mortality.

6. **Recruits and Visual Errors.**—A. A. Bradburne states that the question of the admission of recruits with an optical visual error would be dependent upon two factors only: (1) The nature of the defect; (2) the type of recruit. The nature of the defect would need consideration under the following heads: (1) The defect is of such a nature that without glasses the recruit is practically helpless. Under this heading the great majority would be considered as unfit for military service, although some exception might be made in case of men recruited for home service entirely, where their training in civil life would warrant their employment as clerks in central head offices. (2) When the same condition exists, but affects one eye only, the other possessing fairly good uncorrected vision. The chief point to consider in such cases would be the error in the better eye, and as the man would necessarily be almost entirely dependent on it, the error should, to admit him, be but a slight one. (3) When the defect is such that the glasses make fairly good sight in both eyes into absolutely normal vision with one or both. Here the loss or breakage would form only a slight hindrance to his employment in any branch of the service behind the advanced lines, and might with the glasses enable him to use a rifle with deadly effect. If, moreover, he conforms to the requirements under the heading "Type of Recruit," there seems little objection to his employment, bar the question of replacement in case of breakage. Under the heading "Type of Recruit" comes consideration of: (1) Previous experience in the use of glasses. This factor necessarily must have a great influence in deciding the suitability or otherwise of a recruit. A man who has been accustomed from his youth up to wear glasses has not only obtained better visual acuity than one who takes to them later in life, but has learned to treasure and take proper care of them, and is therefore less likely to break or lose them. (2) The particular branch of the service in which the recruit wishes to serve. It is obviously useless to enlist a man with no knowledge of clerkship in the pay departments, or a "faint heart" into the Army Medical Corps, yet if of engineering taste a place might be found for him in base workshops or even in the Army Service Corps. (3) The general physique and intelligence of the recruit. This factor would frequently turn the scale in his favor or otherwise.

Berliner klinische Wochenschrift.

April 26, 1915.

Essays in the Direction of "Mouth Writing" for the Armless.—Grünberg, a Berlin dentist, relates that the late Professor Joachimsthal had referred to him a man with bilateral arm paralysis in the hope that something might be devised whereby the patient could be enabled to write. Any ordinary prosthesis was out of the question because of the degree of muscular atrophy of shoulder and arm muscles. While "foot writers" are not so rare the author could find no aid from an exhaustive investigation of literature in any other direction. Could a person learn to write with a pen held in his teeth, provided a satisfactory mechanical device could be secured? The teeth were even and strong. Models of upper and lower jaws were so articulated that a space of 2 mm. was left between them. A splint-like formation of wax was introduced so as to extend half way down the crowns of the lower teeth. The upper teeth bit against the lingual aspect of the latter, leaving the labial aspect as well as the angles free. This device, which remains fixed upon the lower teeth when the mouth is shut, was followed by the construction of a special penholder which would necessarily need to be very elastic and flexible in order to spare the neck and head muscles. Such a holder was devised containing three jointed portions. The central one was long, like an ordinary holder. The other two were adjustable, the upper one being held in the teeth, while the lower served to receive the pen. With this device the subject learned to write as well as he had formerly written with his hand. A letter written in a calligraphic hand is shown. Not long afterward a man with an amputated arm was referred to him, and after three months' effort he was enabled to pass the examination of a technical high school, which required a written dissertation. The author admits the existence of several "mouth painters," but can find no information as to how their results are obtained.

Theory of Thyroid Functions and Thyreogenic Disease.—Oswald states that iodine-thyreoglobin is characterized as a substance of quite individual physiological action, not observed in thyreoglobulin, which has no iodine content. Iodine alone does not show this activity. Attempts to iodize various proteins also fail to bring out the latter. Various substances with iodine content, such as corals and sponges, are likewise inert. The substances known collectively as iodothyreoglobulins, which represent a peculiar organic combination, alone represent the dynamic principle of the thyroid. Iodine is no more in evidence in the latter than is chlorine in chloroform. The peculiar action of iodothyreoglobin is this, that it increases nerve tonus to an exquisite degree, not only in the animal but in the vegetative system. It effects this in part by enhancing the adrenalin action upon the vasoconstrictors. It also heightens the activities of the central nervous system and at the same time promotes the catabolism of protein and fat. To understand this in full we have only to study the deficiency symptoms which follow withdrawal of the thyroid functions. In this connection we note the slow metabolism, tardy response of the nervous system, slow heart action, dry skin, mental sluggishness, slow ideation and chilliness. Overaction of iodothyreoglobulin

is seen in the opposite train of symptoms—increased metabolism, heightened response of all the nervous organs, tachycardia, palpitation, sweating, motor unrest, feeling of heat, excitability.

Münchener medizinische Wochenschrift.

April 20, 1915.

Symposium on Shot Wounds of Chest.—Four articles appear in succession in the Military Supplement of this number of the *Wochenschrift* on gunshot and bayonet wounds involving the lungs. These articles are on different aspects of the same subject and represent different clinics—hence they do not represent a symposium in the narrower sense, but are only an example of editorial grouping. Ehret writes a long paper on the treatment of gunshot wounds with special reference to aritficial pneumothorax. The author's material consisted of 100 miscellaneous cases, and of this number not one was lost. He discusses in order the various complications and sequelæ—hemorrhage, pleurisy, empyema, retraction, pneumothorax, pain, pneumonia and bronchitis and emphysema cotis. The treatment was expectant, and surgical intervention was required only in a few cases of empyema. But while there was no mortality, there were many bad functional results—pulmonary collapses with extensive induration being by no means rare, while adhesions and some retraction were the rule. These bad results were due to allowing the exudate to remain in the pleura according to modern teaching. The author recalls the old Trousseau principle of evacuating all extensive exudates by puncture. There are serious objections to this procedure, and the author looked upon the expedient of fractional tapping as too burdensome for the patient. As a way out of the dilemma he therefore resorted to the procedure of Wenckebach which combines puncture with artificial pneumothorax, in which air is made to replace the punctate. Of his 100 cases 13 were treated in this manner. He concludes from his results that this resource promises well for the relief of pressure conditions due to large exudates. Krez reports 28 cases of bullet wounds of the lung and discusses the problems of convalescence. To accelerate recovery, especially in slow progress he would employ fresh air, pneumatic chambers, hydrotherapy and any other available resources. Despite all, however, a shot lung remains for a long time an inferior lung for breathing purposes. Not infrequently an obstinate bronchial catarrh develops in the wounded lung. Unverricht reports a case of lung wound without symptoms. A patient presented himself at Jessen's sanatorium at Davos for mild tuberculosis. The radiogram showed the presence of a bullet in the left side of the thorax. Patient recalled that early in the war he was struck on the forearm by a bullet. He fell at once and the wound bled profusely. There were no symptoms of pulmonary injury. The surgeon was somewhat amazed that a man should drop flat from a flesh wound of the arm. The left lung was free from tuberculosis, old foci of which were seen in the right apex. The sear of the bullet wound in the arm showed no foramen of exit. The tract of the bullet was close beneath the head of the humerus. The point of the bullet in the lung was toward the axilla, showing that it had made a turn. The velocity of the projectile had evidently been mostly spent, and the obstruction of the soft parts was sufficient to turn it about. For the same reason the lung had not been torn.

Treatment of Bayonet Wounds of the Lungs.—Herrenschneider reports a single case of this form of traumatism. A soldier who was bayonetted in a trench fight was able to withdraw the weapon. Hemorrhage was marked, and there was vertigo but no syncope. For several days there was increasing dyspnea and pain in the right side of the chest. Hemoptysis was absent. Patient felt fairly well at the end of this period, and walked by stages to a reserve hospital. He arrived very tired, and his general health was poor (anemia, reduced nutrition). The chest had been penetrated beside the strenum. There were evidences of an old hemorrhage in the pleura. Evening temperature was high. Patient was relatively comfortable in bed for four weeks and nothing was done until at the end of this period when a second punctate was obtained and cultures made with negative results. He was still kept at rest until temperature was nearly normal, and anemia was showing improvement. Sent home, his improvement was rapid, but for full recovery it was necessary for him to take a resort cure.

Deutsche medizinische Wochenschrift.

April 8, 1915.

Ekehorn's Operation for Rectal Prolapse in Children.—Tölken states that we have never had an ideal treatment for this condition, doubtless because each surgeon lays stress on some one particular causal element. At present, however, all are united in the belief that the most important causes are insufficiency of the muscular floor of the pelvis, abnormal depth of the Douglas fold and relaxation of the suspensory bands of the pelvic rectum. One must add to these the physiological steepness of the coccyx in the young child, which gives no firm support to the rectum, the abdominal pressure making itself felt directly by the muscular floor of the pelvis. Active influences are diarrhea, cough, and bearing down. However, within a comparatively short time these anatomical conditions are quite outgrown, and prolapse may also be compated successfully by minor measures. Naturally in the adult conditions are quite different. The Thiersch wire ring is very popular in Germany, although failures and occasionally accidents occur under its use. In 1909 Ekehorn, a Swede, devised the following technique. He first reduced the prolapse under narcosis. The left index finger is allowed to remain in the rectum. Then close to the sacrum, lower segment, a needle is passed into the rectum, against the surgeon's finger and brought out by the anus. A strong silk thread is threaded into this needle which is then withdrawn through the needle opening. The process is now repeated on the opposite side with the same thread. There are now two loops of thread in the rectum, the ends of which are knotted over the sacrum. The threads are removed in two weeks. Practically there is no postoperative treatment. The operation is, therefore, only a rectopexy, the bowel being fixed against the sacrum. The author has varied this procedure by using a wire suture, fastened behind by means of a lead plate or bullet. While Ekehorn used a needle with a handle, Tölken finds the ordinary needle to give as good service. Properly carried out, the patient is radically cured as soon as the operation is finished; and with proper precautions there should not be any disturbance in regard to healing. None of the operations are to be performed until the usual conservative measures have all been tested. The only fear is of infection; but thus far there has been no case of the latter. Yet the material of the operation is still very small. By reason of the very large number of resources in use for rectal prolapse—which incidentally includes tamponades, celluloid corsets, paraffin injections, in addition to numerous operations—the Ekehorn procedure seems to be the simplest, most conservative and safest yet attempted.

Insurance Medicine.

THE GENERAL FACTORS DETERMINING MEDICAL SELECTION.

FROM "ALLGEMEINE LEBENSVERSICHERUNGSMEDIZIN" BY PROF. DR. GEORG FLORSCHÜTZ OF GOTHA.

(*Continued from page* 957.)

The medical directors of this company knew well how to meet the tuberculosis hazard in which heredity and early disease afforded a handle for selection, but they failed completely in regard to the habitus phthisicus or, as Kraus more correctly terms it, the habitus asthenicus, because they did not give the necessary attention to emaciation. For only thus can it be explained that in a series of cases in which the inferior constitution alone could warn, there occurred 61 actual deaths with an expectancy of but 8.7, or in other words, a supermortality of 600 per cent. In another series in which the same heredity factor was concerned the supermortality had indeed sunk to 89 per cent., but only in those cases in which suspicious earlier diseases pointed more distinctly to the hazard, did it sink to 14 per cent.; while in all other groups in which the constitution factor was good (with the exception of a slight supermortality in 2) a more or less marked degree of submortality was attained.

But why seek for further proofs where the results speak for themselves? While the tuberculosis mortality of the Gotha Life Insurance Company for the first five insurance years (total expected mortality = 100) in the years subjoined was as follows:

1829-1851	156.6%
1852-1866	109.3%
1867-1880	107.0%
1881-1895	86.0%

In the period 1904-1909, when the selection was based strongly on the constitutional factor, it had sunk to 28 per cent.

What then will the assertion of Cornet signify that the habitus paralyticus is not only no forerunner and still less the cause of tuberculosis, but a consequence of it and not a common one at that. It is very probably one of the conditions for the occurrence of the disease, indeed so powerful a one that I am willing to assert that in life insurance the acceptance of applicants with the tuberculosis hazard depends not on the hereditary taint but upon the constitution alone. The better this is the less the danger of death from the hereditary evil.

It is self-evident that we will not therefore define the disposition. We seek only to determine the definite anatomical condition of the organism at a time when there is as yet no talk of a disease demonstrable through clinical investigation, to recognize that in such an organism the probability of death from tuberculosis is far greater than in another individual who is differently constituted.

From the first we leave the *Bacillus tuberculosis* quite out of count, for with the many sided opportunities for possible infection it must be reckoned as ubiquitous with us. At the same time we do not underestimate its importance and above all we are thankful to bacteriology because through its study so much has been contributed to our understanding of the soil, which latter we have now learned correctly to estimate. But practically its study avails us nothing. We have to exercise selection and we cannot progress a step by simply learning that the frequency of infection increases with the opportunities. We would learn to know the factors which so bring it about that certain individuals have a greater mortality from tuberculosis than others who have had the same exposure.

We would discover the recognizable qualities of the individual which announce the want of resistance to infection. For only then do we know how to go about to exercise a correct selection.

Leanness, the habitus asthenicus, is one of the conditions which cooperates in the occurrence of tuberculosis, and before all the one which is most accessible to investigation. All that is required are the tape and scales to bring it, grossly but numerically, to observation. Moreover, we do not need here anything else, for it is now possible to establish the probability with which *ceteris paribus* the dreaded event supervenes. Therewith we can calculate the probability that a thin applicant will or will not die of tuberculosis.

And to proceed otherwise we have no choice, as long as medicine does not place at our disposal methods of investigation which will teach us to know directly the danger of tuberculosis.

There are, indeed, prospective methods but all these biological and chemical reactions are merely diagnostic and not prognostic aids. They are all difficult of application by the medical examiner, especially the most trustworthy of them, tuberculin injection. We get no further with it than we might expect to get with the so frequently dubious finds at the right apex—which clinically have nothing to do with tuberculosis—and in general practice also no harm is done, for simple observation suffices to fix the correct diagnosis. In insurance examination, however, this find becomes a real stumbling block because slight dullness over the clavicle, prolonged expiration, sharpened inspiration must always excite the suspicion of tuberculosis, and the period necessary for observation as a diagnostic accessory would only mean a rejection. A readily applicable, trustworthy reaction would be of very great importance for life insurance.

I will take up briefly one more point in the diagnosis of tuberculosis because it is frequently brought into the field by the medical examiner in respect to the refusal of an applicant regarded as hazardous because of his habitus. This is, that the applicant examined has a large chest expansion and that this speaks against the danger of phthisis either outright or at least as a factor which should be thrown into the scale in favor of the applicant.

(*To be continued.*)

Health Insurance—Nature of Disease.—Action was brought upon a health policy which contained the provision that "benefits shall not be allowed for disease not common to both sexes." The plaintiff was afflicted with a cystic tumor on one of her ovaries. The only question was whether such tumor was a sickness or disease not common to both sexes. Three medical witnesses testified that it was common to both sexes. The medical director of the defendant testified that it was not common to both sexes, but admitted that the male sex did have cystic tumors. The jury found, as it was held they were authorized to do from the evidence, that the disease was one common to both sexes.—Russell v. Fraternities Health and Accident Association, Maine Supreme Court, 92 Atl. 820.

Book Reviews.

THE CLINICS OF JOHN B. MURPHY, M.D. Vol. III, No. 5. Octavo of 190 pages with 61 illustrations. Published bi-monthly. Price per year, paper, $8.00; cloth, $12.00. Philadelphia and London: W. B. Saunders Company, 1914.

THE first 60 pages of this issue are given over to clinical talks on surgical and general diagnosis by Dr. Murphy and Dr. Mix, and cover a number of renal conditions, intrathoracic sarcoma and meningitis. In the opinion of the reviewer the most valuable part of this section is that in which the differential diagnostic points are brought out in connection with the case of intrathoracic sarcoma. Murphy's discussion of traumatic epilepsy while operating upon such a case is also very instructive. Other subjects discussed in connection with operation are: Epithelioma of the glans penis; carcinoma of the corona penis with metastasis in the inguinal glands, in which the occasional cystic type of metastatic glandular involvement is well shown; fecal fistula; hypertrophy of the prostate; imperforate anus, and the use of radium and the *x*-ray in the treatment of cancer. In addition, about 70 pages are given over to the discussion of bone and joint work, not a little of which has been covered in previous issues. Sixteen illustrations of the method of doing arthroplasty of the elbow and knee joints give a very clear idea of Murphy's technique. All things considered it is one of the best of the recent numbers of the Clinics.

GONORRHOEA AND ITS COMPLICATIONS IN THE MALE AND FEMALE. By DAVID WATSON, M.B., C.M., Lecturer on Venereal Diseases to the University of Glasgow; Surgeon in Charge of the Venereal Department Glasgow Royal Infirmary; Late Surgeon Glasgow Hospital for Women; Late District Surgeon Glasgow Maternity Hospital, etc. With 72 illustrations and 12 plates, 9 of which are in colors. Price, $3.75 net. New York: Paul B. Hoeber, 1915.

"THE object of this book is to place at the disposal of the practitioner and student a review of the work, as I understand it, of the many scientists and clinicians, to whose labors any merit that this book may possess is due." So states the author his reason for presenting another book to the already well-filled field. It consists of twenty-seven chapters covering three hundred and sixty pages of text. Beginning with the history of gonorrhea, its bacteriology, pathological histology, the various phases of acute and chronic urethral infection in the male and their treatment are discussed. Four chapters are given to gonorrhea and its complications in the female. Following in logical arrangement are the chapters on infections of the urinary organs common to the sexes, the eye, gonorrheal rheumatism, septicemia and, lastly, modern advances in serology. Little or no reference is made to the sexual debilities sequential to gonorrheal invasions of the adnexa. Among the commendatory features are the sections on bacteriology and pathological histology of the disease, since those for whom the work is intended must perforce know these well ere they can intelligently direct treatment. The treatment advised is that of our accepted masters. The technique of the manipulative procedures is clearly described, especially that of urethroscopy. When the author speaks of a urethroscope as "internally lit," he doubtless refers to the "direct illumination" type. Many urologists will take issue with him in his approval of a rigid prostatic masseur, since its use is most often dangerous or valueless. American urology is complimented by the free draft upon the work of our writers, as well as that of his European confrères. The literary style is good, only here and there suffering from irregularities and lapses into the magisterial tone, faults which many medical writers are prone to commit. The illustrations are clear and well-chosen. The color plates are taken by permission from Chetwood's "Practice of Urology."

DIAGNOSTIC AND THERAPEUTIC TECHNIC, a Manual of Practical Procedures Employed in Diagnosis and Treatment. By ALBERT S. MORROW, A.B., M.D., Clinical Professor of Surgery in the New York Polyclinic, etc. Second Edition, Thoroughly Revised. Price, $5.00 net. Philadelphia and London: W. B. Saunders Company, 1915.

THE second edition of this well and favorably known manual has been slightly enlarged in the process of revision to which it has been subjected but has lost none of its thoroughly practical nature. It includes a detailed discussion of most of the ordinary diagnostic and therapeutic procedures written in clear and concise language. The volume is profusely illustrated and there has been no hesitation in repeating illustrations where such repetition would aid in the understanding of the text. It is rather a surprise that the author has not included any mention of the uses of tuberculin in diagnosis and therapy. It would seem safer if he were to insist on the wisdom of the wearing of rubber gloves in many of the measures described, especially where intrauterine manipulation is involved. In the discussion of the methods of transfusion, but slight mention is made of the various syringe methods and their modifications, which are so valuable in that their use does not necessitate the tying off of a vein. Laboratory workers would thank him if he had advised that smears of exudates for diagnostic purposes be made at the end of the slide so that the staining process would be a little easier. Also it is probably not a general practice to make blood cultures directly upon agar slants, a procedure that is apparently recommended.

THE CLINICS OF JOHN B. MURPHY, M.D. Vol. III, No. 6. Octavo of 175 pages, with 51 illustrations. Published bi-monthly. Price, per year, paper, $8.00; cloth, $12.00. Philadelphia and London: W. B. Saunders Company, 1914.

THE final number of the Clinics for the year 1914 has for a prelude a series of plates showing the new building and offices of Dr. Murphy and his staff, apparently a beautiful building and luxurious offices to be sure, but ——? For the postlude we have the index for the year—useful and understandable. In the section on general and surgical diagnosis a great many useful points are brought out. The first case in this section, one of fracture-dislocation at the level of the twelfth dorsal vertebra, is very interesting and the diagnostic points leading to the localization of the lesion are well brought out by Dr. Mix, who also contributes the discussion of a case of Hodgkin's disease. Murphy himself discusses appendicitis, based upon several cases, and the differential diagnosis of a case of cholecystitis from appendicitis and pyelitis. Many of the points have been emphasized in former lectures but will bear iteration and reiteration. A preliminary report on autosensitized autogenous vaccines is made by Kreuscher of Dr. Murphy's staff. The regular clinical lectures then follow, based upon five bone and joint cases, bilateral tuberculous epididymitis, gummatous tumor of the testicle, perforating duodenal ulcer, and retroperitoneal sarcoma of the upper abdomen. Except for the exhibition of horribly bad taste in the prelude, this is a commendable number.

DIE EXPERIMENTELLE PHARMAKOLOGIE ALS GRUNDLAGE DER ARZNEIBEHANDLUNG. Ein Lehrbuch für Studierende und Ärzte von Dr. HANS H. MEYER, Wien, und Dr. G. GOTTLIEB, Heidelberg, Professoren der Pharmakologie. Dritte, neubearbeitete Auflage. Price, 15 marks. Berlin and Vienna: Urban & Schwarzenberg, Wein. Rebman Company, New York, 1914.

THE new edition of this work embodies the changes which have taken place in this subject since the appearance of the scond edition three yars ago. A few new drugs have received consideration and the book is only slightly enlarged in the revision. The arrangement, like that of the former editions, is by systems of the body, *i.e.*, the nervous system, the muscular system, etc., and by organs, a method that has much to commend it. The few errors of the former edition have been corrected. It is probably the best and the most complete book which we have on the subject.

WORRY AND NERVOUSNESS, or the Science of Self Mastery. By WILLIAM S. SADLER, M.D., Professor of Therapeutics, the Post-Graduate Medical School of Chicago; Director of the Chicago Institute of Physiologic Therapeutics; Fellow of the American Medical Association. Price, $1.50 net. Chicago: A. C. McClurg & Co., 1914.

DR. SADLER acknowledges in his preface the help and inspiration which he has received from the works of Janet, Ford, Prince, Breuer, and Dubois. He is personally most optimistic as to the prognosis of neurasthenia, but there is much cheery wisdom in the advice to nervous women of leisure to get them to the settlements, the modern nunnery, and the emphasia he lays on the value of well chosen work. The success of Christian Science is explained with admirable tolerance and humor.

Society Reports.

ASSOCIATION OF AMERICAN PHYSICIANS.

Thirtieth Annual Meeting, Held in Washington, D. C., May 11, 12, and 13, 1915.

THE PRESIDENT, DR. SAMUEL J. MELTZER O. NEW YORK, IN THE CHAIR.

Tuesday, May 11—First Day.

President's Address.—DR. SAMUEL J. MELTZER of New York delivered this address and first called attention to Dr. Delafield's statement made in June, 1886, as follows:

"At the inauguration of a new medical association it would seem proper for the presiding officer to say some words concerning the objects of the association and the best methods of carrying those objects into effect, and it was my intention to do this; but when I considered the character and attainments of those whom I was about to address such a plan seemed to be unnecessary and even impertinent. We all of us know why we are assembled here today. It is because we want an association in which there will be no medical politics and no medical ethics; an association in which no one will care who are the officers and who are not; in which we will not ask from what part of the country a man comes, but whether he has something to say worth hearing, and can say it. We want an association composed of members, each one of whom is able to contribute to the common stock of knowledge, and where he who reads such a contribution feels sure of a discriminating audience. We are all busy men, ambitious men. We all like to give instruction and to gain reputation, and both of these we can do in the societies already existing. But we also want a society in which we can *learn* something. And this, I take it, is the real object of the enterprise which we inaugurate today—to form an Association of Physicians and Pathologists to which we may come year after year with the well founded hope that at each meeting we will find something to *learn*."

Dr. Meltzer said he had been engaged in the practice of medicine for thirty years and had been during this time in close association with the other sciences and he believed that they should all endeavor to increase their knowledge of clinical medicine especially. He advised that they should get together more often and help one another, take a deeper interest in medicine, and be able to grasp what it all meant. The best men in the future would be the brainy men, those who had spent many years in studying the various methods of acquiring knowledge from the medical sciences, and who would apply all their knowledge in combating diseases. Clinical medicine and the medical sciences must be brought closer together and work in harmony. Dr. Meltzer said that he had been told that the papers read before the Association were "above their heads." They should not forget that the science of medicine was progressive and they had no right to halt because there might be some who were left behind.

Report of the George Washington Memorial Committee.—Dr. JAMES TYSON of Philadelphia, chairman, said that this committee had been appointed to raise a fund of $5,000, but so far it had only collected $200. Circulars asking for appropriations were sent out as long ago as 1912. The committee was so discouraged that it recommended that the project be given up and the subscriptions, all small in amount, be returned to the donors. This was agreed to.

Important Contributions to Clinical Medicine During the Past Thirty Years from the Study of Human Blood Pressure.—Dr. THEODORE C. JANEWAY of Baltimore read this paper. He said that in 1886 the literature on human blood pressure gave twelve different types. However, today the methods employed were of sufficient accuracy and so available that blood pressure should be taken in valvular diseases, in brain diseases and other diseases and as a routine procedure. To find a law blood pressure was of little value in making a diagnosis. In tuberculosis the taking of the blood pressure was of no value at all. In America one man had report examinations made of 28,000 healthy adults and he found that the average blood pressure increased with age. Dr. Janeway presented Fisher's statistics of 19,339 with ages and average blood pressures as follows:

Ages	Average Blood Pressure
18-20	119.85
21-25	122.76
28-30	123.65
31-35	123.74
36-40	126.96
41-45	128.56
46-50	130.57
51-55	132.13
56-60	134.78
General average	128.91

The Present Status of the Electrocardiographic Method in Clinical Research.—Dr. ALFRED E. COHN, Hospital of the Rockefeller Institute for Medical Research, New York City, (by invitation) presented this paper. He said that the electrocardiographic method had been used in clinical medicine for only ten years. It recorded the electrical discharges of the heart during its activity. The form of the curve remained constant through the greater portion of life. Any change in it represented a change in the heart or in its position. The normal curve depended on the orderly performance of four chief functions: first, on the orderly spread of electrically excited states; second, on the orderly sequence of auricles and ventricles; third, on the orderly coordination of the muscular mass of each pair of cavities; fourth, on the usual disposition and volume of the muscular mass of each pair of cavities. The abnormal electrocardiogram depended on a disturbance of one or more of these functions. Under the first head were grouped both auricular and ventricular extrasystoles, paroxysms of tachyardia, and changes in the *T* wave; under the second head, heart-blocks of various kinds; under the third head, the split *P* wave when there was auricular asynchronism in mitral stenosis, auricular fibrillation and flutter, ventricular asynchronism, and ventricular fibrillation; under the fourth head, the changes due to hypertrophy and dilatation and dextrocardia.

The Physiology and Pathology of the Duodenal Mucous Membrane.—Dr. THOMAS R. BROWN of Baltimore discussed this subject both as regarded its motor and secretory functions, and especial attention was paid to its rôle in connection with pancreatic secretions, and in causing the toxic symptoms met with in high intestinal obstruction.

Observations on the Use of the Duodenal Tube for Diagnosis and Treatment.—Dr. FRANKLIN W. W. WHITE of Boston read this paper. He said that the clinical use of the duodenal tube (introduced by Einhorn and by Gross in 1909-10) had proved its value in a limited field. The tube was used by the author in 86 cases; in 66 for diagnosis; in 20 for treatment. A fluoroscopic study of the technique of the introduction of the duodenal tube showed that by placing the fasting patient successively in simple postures, the tube might be introduced into the duodenum within one half hour in a majority of cases where organic stenosis was not present. Spasm of the pylorus, atonic and hook shaped stomachs might delay the tube. A heavy (Gross) tube tip entered the duodenum more rapidly than a light (Einhorn) tube tip. A small tube No. 8 French with a heavy tip of at least 100 grains weight (Palefski) was best of all for diagnostic work. It was not difficult to tell the position of the end of the tube. It was as safe as an ordinary stomach tube. In diagnosis, examination of the duodenal contents was most useful in diseases of the pancreas and in cases of chronic jaundice. It was the only method of directly obtaining the secretions of the pancreas and liver. There was considerable normal variation in the pancreatic ferments; only absence or marked diminution had much value in diagnosis. Examination of the feces in some cases was almost equally valuable and simpler; in others the examination of the duodenal contents was much more valuable. In treatment the duodenal tube (Einhorn) was useful in a limited group of cases of peptic ulcer. (It was only used in cases without organic obstruction and in cases resisting ordinary medical treatment.) It might be used to improve the patient's condition before operation, in ptosis and atony with delay in emptying the stomach and vomiting, and it had considerable value in cases of persistent vomiting of nervous and toxic type. Here an unusually long tube was desirable to prevent regurgitation into the stomach. It was used in two cases of cancer of the esophagus (stomach feeding). Almost every case was improved by duodenal feeding and in a considerable number the symptoms stopped. It was superior to rectal feeding as patients kept their weight or gained. A thermos bottle as reservoir and the Mur-

phy drop method was preferred to a syringe for introducing food.

Chronic Duodenal Ulcer.—Dr. WILLIAM J. MAYO of Rochester, Minn., read this paper. He said that the post-mortem statistics of chronic duodenal ulcer had been very misleading. The work of Rokitansky, Brinton, and Welch represented splendid research in their day, but that was thirty to seventy-five years ago. Even acute perforations were not always recognized post-mortem because of the accompanying generalized peritoneal infection. The clinical diagnosis of duodenal ulcer was even more chaotic until within a recent period. Ten years ago the statistics of three large hospitals showed almost no duodenal ulcers and varied in the clinical frequency of gastric ulcer with the same clientele from .13 per cent. to .48 per cent., both falling short of the post-mortem findings three to eleven times. In Germany the change of opinion as to the frequency of duodenal ulcer has been very remarkable during the last two years, their recent surgical literature showing a percentage as high as was shown in this country. These cases were not diagnosed in the past or they were called gastric ulcer, nervous dyspepsia, or hypochlorhydria. The modern view was the result of operating room findings. A large majority of ulcers in the vicinity of the pylorus which had been called pyloric ulcers were in reality duodenal. Gastric ulcers in the terminal inch and a half of the pylorus would probably be mistaken for carcinoma on account of the tumefaction due to edema and muscular hypertrophy. Our statistics showed 73 per cent. duodenal ulcers to 27 per cent. gastric ulcers. In typical duodenal ulcer the history was the most important diagnostic feature, the Roentgenogram second, the physical diagnosis including the use of the stomach tube third, and the laboratory diagnosis a poor fourth. Many duodenal ulcers gave atypical histories because of coincident disease of the gallbladder or appendix, so that a differential diagnosis at the operating table must be made in each case. Unless the duodenal ulcer could actually be demonstrated at the operating table, the operation should not be done. Symptomatic evidence could not be accepted to the contrary. The large majority of ulcers involved the first two inches of the duodenum and 83 per cent. were in men. Gastroenterostomy was the operation of choice. Excision combined with the Finney gastroduodenostomy was occasionally valuable to meet certain indications. Blockage of the pylorus was unnecessary unless there were symptoms of impending perforation or hemorrhage. The majority of the so-called recurrences of duodenal ulcers, after operation, were due to improper technique, especially to the use of continuous nonabsorbable sutures of silk or linen, which might cause a gastrojejunal ulcer, thickening of the stroma and adhesions and required many months before the thread was cast off. These patients usually obtained relief for some months following operation; the symptoms then recurred and were supposed to be due to dietetic errors. In cutting off more than 100 gastroenterostomies which had been made for sypmtomatic ulcer they had been wholly unable to find evidence of gastric or duodenal ulcer or that there had ever been one. Blocking the pylorus would not help to cure these patients who had been unnecessarily operated on. The scar left from the blocking introduced cicatricial changes which bore false testimony of the existence of an ulcer when re-operation was undertaken.

Chronic Duodenal Ulcer.—Dr. FRANK BILLINGS of Chicago considered the hematogenous infectious origin of this disease and said that chronic ulcers of the stomach and duodenum were properly named peptic ulcers. Pepsin required the presence of free hydrochloric acid to combine with and digest albumins. Free hydrochloric acid with pepsin was corrosive in action upon a granulated ulcer and tissues weakened by necrosis and malnutrition. Clinically, duodenal ulcer might be classed with chronic gastric ulcer located in the pyloric area; the symptom complex and medical management were practically the same. The principles of medical management included the removal of the sources of infection and the prevention of corrosion by the gastric juice. Surgery would correct the first. Rest, frequent feeding and the use of adequate amounts of alkalies would abolish the presence of free hydrochloric acid in the gastric juice and prevent further corrosion and permit healing to take place.

A Case of Severe Anemia with Leg Ulcer and Remarkable Blood Findings.—Dr. JEROME E. COOK and Dr. MEYER of St. Louis, Mo., presented this paper which was read by Dr. George Dock. The case reported was one of severe anemia with unusual red cell findings, occurring in a young mulatto girl. There was a complication of recurring, indolent, leg ulcers. The red cells showed the greatest degree of variation both in size and shape, giving the appearance as if many of the cells had been broken into fragments. But the most frequent abnormal type was the much elongated, curled red cell often more or less sickle shaped. Among the white cells an eosinophilia of varying and sometimes intense degree was the most marked feature. Two brothers and a sister, the other children in the family, were dead and all suffered from severe anemia. Two similar cases had been found in the literature, both cases being mulatto and both had a chronic type of leg ulcer.

Clinical Studies in Blood Transfusion.—Dr. E. LIBMAN and Dr. R. OTTENBERG of New York presented this communication. They stated that the real value of transfusions and the real indications for them were becoming better understood as a result of a large number of transfusions that had been done since Crile's introduction of direct transfusion. They had studied 212 transfusions in 189 cases at the Mount Sinai Hospital in New York. In typhoid fever, the results were exceedingly encouraging. Among seven transfusions done for typhoid hemorrhage, four were successful in relieving the immediate symptoms of hemorrhage. Two transfusions in protracted cases of typhoid exerted a very beneficial effect on the course of the typhoid itself and the authors recommended that in typhoid cases at the first indication of blood in the stools preparations be made so that a transfusion could be done at short notice if it should be necessary, and that in protracted cases of typhoid state, transfusion should be tried as a reviving effect on the patient. Possibly such transfusions would be more advantageous if a donor who had recovered from typhoid or who had been immunized against typhoid could be used. In the three cases of ectopic pregnancy seen by the authors transfusion was life saving. Among the most satisfactory transfusions in the whole series were some of those done preliminary to operation in patients whose desperate condition would otherwise have contraindicated any other operation. There were twenty-three such preoperative transfusions and in thirteen of them the result was decisive and the patients recovered. In shock, on the other hand, the results were very disappointing. The authors thought, however, that if shock could have been foreseen so that the transfusion could have been done immediately instead of after several hours delay in obtaining a donor, the results might have been better. Perhaps the best results in all the series of cases were those in the group of hemorrhagic conditions. The authors discussed those cases under three heads—purpura hemorrhagica, hereditary hemophilia, and symptomatic hemorrhagic diathesis. Of purpura hemorrhagica there were nine cases, all of them very severe, as no one had as yet advocated doing transfusions in the milder cases of this disease. Of the nine cases, six recovered completely and one left the hospital improved. The prompt cessation of the hemorrhage in most of the cases was very striking. The authors speculated as to what effect the blood transfusion might have had on this disease and pointed out that it was probably not due to restored coagulability (as it was in hemophilia), because in most cases of purpura the coagulability of the blood was not impaired. The two fatal cases of purpura hemorrhagica formed a peculiar group in that they were both cases of post-partum purpura hemorrhagica (in which the ordinary kinds of bacterial infection could be excluded). They suggested that possibly this was a separate type of disease with a pathogenesis different from that of the other cases. In hemophilia the transfusion treatment had an almost specific effect. In five of the six cases transfused the hemorrhage stopped promptly, and the coagulation property of the blood became practically normal. In the cases that were followed for some period of time, however, the deficient coagulability always returned after some weeks or months. On the basis of this observation the authors suggested a plan of prophylactic treatment for hemophilia. This was particularly important because, as was well known, hemophilia was a very fatal disease and the majority of persons afflicted with it never reached adult life. They suggested that every individual known to have hemophilia ought to have at his command several persons whose blood, by previous tests, was known to be compatible with his. Whenever serious hemorrhage occurred prompt transfusion should be done. Beside this a small intravenous injection (25-50 c.c.) of whole

blood should be given to such persons regularly at intervals long enough to have some continued effect. It was possible that if this was done the hemorrhage could be prevented and the majority of hemophiliacs able to lead a life of normal duration. In discussing the value of Weil's serum treatment in hemorrhagic diseases, Dr. Libman and Dr. Ottenberg were not in entire accord, though they believed that the serum treatment deserved a further trial. In almost all of the thirty-five cases which had been transfused for hemorrhagic disease, however, serum treatment had been tried out thoroughly before the transfusion and had had no effect. In various types of hemorrhagic disease secondary to other conditions in general transfusion helped to check hemorrhage, but only did so permanently if the original condition could be relieved. In cholemic hemorrhage the results were rather disappointing; only one of the seven cases recovered. They suggested that in these conditions the blood and the viscera were so badly damaged that only very large and possibly repeated transfusions so as to replace a very large part of the patient's own blood would be effective. They devoted considerable time to the discussion of pernicious anemia in which they had studied twenty-four cases. Thirteen of the cases underwent more or less prolonged remissions immediately following the transfusion. The cases which underwent remissions were generally cases of longer duration than the cases which failed to undergo remissions and the authors suggested that there were two types of pernicious anemia—one, a type with a rather definite onset and reaching a severe grade of anemia within three to six months, in which transfusion did little good; the other, a type with a less definite onset and slower progress, which tended to undergo remission spontaneously and in which new remissions could be brought about by transfusion. It seemed wise to do a large enough transfusion to overcome the anemia to a considerable extent because this tended to break the vicious circle caused by apparent degeneration resulting from the anemia itself. Nevertheless remissions sometimes occurred after small transfusions. The effect of the transfusion was remarkable on the general condition of the patient—the fever usually disappeared, the appetite returned, although apparently the hydrochloric acid did not return to the gastric secretion. In regard to pernicious anemia the authors concluded that transfusion was the best remedy and that though it never cured it led to remission in about half the cases. They recommended that if the first transfusion failed to bring about a remission one should be tried from a different donor, as they had seen two cases in which a second transfusion did bring about a remission. With regard to splenectomy in pernicious anemia they had seen two cases in one of which it was very successful, in the other not. They believed that splenectomy had about the same effect as transfusion, namely, brought about a remission, and that judging from the experience up to date it should be reserved as a final method of producing remission when transfusion would no longer do so. In leucemia, the results were interesting. In myelogenous leucemia and acute lymphatic leucemia transfusion was without effect, but in four of the five cases of chronic lymphatic leucemia transfusion was followed by a remarkable remission in which the blood picture returned temporarily to the normal. The ultimate outcome of course was not affected. In bacterial infections, transfusion was only of value in so far as it restored the general resistance of the patient. In cases of acute infection with pyogenic organisms of which the authors reported ten cases, transfusion was not of much value, but in protracted cases, particularly those of pyemia, transfusion sometimes produced remarkably brilliant results. In subacute bacterial endocarditis transfusion was of great value in combating the anemia and the general weakened condition. The authors suggested that in acute infectious diseases, particularly in those diseases in which no serum immunity had yet been demonstrated and in which it was therefore likely that the body cells (including the blood cells) and the carriers of immunity, transfusions be done from donors who had recovered and were therefore immune. This should be tried in malignant cases of the exanthemata. In gas poisoning, transfusion was almost a specific treatment and should be accompanied by phlebotomy. In diabetic coma it was useless. The authors then discussed certain technical questions which affected the indications for transfusion. They pointed out that by careful performance of the tests for hemolysis and agglutination of either donor's or patient's blood by the other, the danger of fatal accidents due to this cause could be absolutely excluded. They had had no such accidents in any of their cases in which this difficulty was so excluded, but had had three accidents in cases in which it was not. The danger of doing too large a transfusion was considerable, especially in cases where the heart action was already impaired. The amount of blood which ought to be transfused should be calculated out and strictly adhered to. The authors described two cases of serious accidents due to excessive transfusion. They discussed the methods of obtaining donors and stated that it was wise to have the donor, before transfusion, sign a legal form relieving the patient and the surgeon from liability. In discussing the question of the donor during the transfusion, they stated that fluids should be given freely, but that whiskey should be avoided as it seemed to cause vomiting when the patients became anemic. They discussed the various technical methods of performing transfusion and believed that the syringe method at present was best on account of the fact that it was very simple, and since it did not injure the vein could be repeated as often as necessary on the same patient.

The Treatment of Tetanus with Antitoxin Given Intraspinally.—Dr. MATTHIAS NICOLL, JR., of New York said that the best treatment of this disease was preventive. Magnesium sulphate and carbolic acid by Baccelli's method together with antitoxin was usually given. The results were frequently disappointing because it was given too late and in too small doses.

The Treatment of Acute Lobar Pneumonia by Specific Methods.—Dr. RUFUS COLE of New York presented this paper. He said that a study of the pneumococci isolated from cases of pneumonia indicated that these organisms might be divided into four groups. Two of the types were differentiated by immunological methods, and every member of each of these groups seemed to be identical with every other member of the same group, so far as immunological characters went. In Group III were placed the organisms which had been described as *Pneumococcus mucosus*. In the fourth group were placed, at present, all the remaining organisms. Each race of this group seemed to be distinct immunologically. The studies made at the Hospital of the Rockefeller Institute and at the Pennsylvania Hospital, in Philadelphia, indicated that about 35 per cent. of the cases of pneumonia were due to organisms of Type I, about 30 per cent. due to organisms of Type II, 5 to 10 per cent. due to organisms of Type III, and the remaining 25 per cent. due to organisms of Group IV. The cases due to the different types of organism differed in regard to severity. The mortality in the cases due to organisms of Type I was 25 to 30 per cent., to organisms of Type II 30 to 35 per cent., to organisms of Type III 50 to 60 per cent., or even higher, while the mortality in cases due to organisms of Group IV was much lower, probably under 10 per cent. It was evident from these studies that the determination of type of organism in the individual case was of considerable importance from a prognostic standpoint. Quite extensive studies had been carried on in the hope of isolating the toxin elaborated by pneumococci. If this poison could be detected it was possible that methods for overcoming its effects, either by chemical or biological measures, might be found. So far it had been impossible to detect the presence of poisons in cultures of pneumococci or in the body fluids of animals infected by them. It had been possible to show, however, that when pneumococci were placed in salt solution and allowed to undergo autolysis, or when the bacterial bodies were caused to undergo solution, either by addition of bile or by first freezing and then grinding the bacteria in salt solution, the extracts or solutions so prepared, when injected intravenously into guinea pigs, were very toxic. These solutions were also hemolytic, and by injection of these solutions into animals it had been possible to produce antihemolytic sera, but, so far, it had been impossible to produce sera which were able to neutralize the toxic effects of the solutions when injected into guinea pigs. The efforts, therefore, to produce antitoxic sera to pneumococci had not yielded promising results. It was not certain, however, that pneumococci produced their effects by the elaboration of poisons which might be isolated. Among the phenomena produced by pneumococci was the production of methemoglobin from oxyhemoglobin, when red blood corpuscles were added to the pneumococcus cultures. Studies of this reaction had shown that, for this reaction to occur, living pneumococci must be present and, in addition, a small amount of nutritive material. For this reaction to occur, therefore, the bacteria must be living and carrying on their

nutritive functions. No toxin could be found, however, either in the culture fluid or in extracts of the bacterial bodies, which was able to bring about this reaction. It seemed, therefore, that the reaction was caused by changes due to some modification in the conditions immediately surrounding the bacterial cells. If pneumococci could cause this reaction, merely by contact, and without the production of soluble toxins, it was quite possible that they might produce other effects on tissue cells in a similar manner. If the main effects of pneumococci upon the body were due to the action of the living bacteria, and not to toxins elaborated by them, it was quite probable that the only satisfactory serum for use in pneumococcus infections would be one produced by the immunization of animals to the living bacteria. Such sera had now been produced against organisms of Type I and Type II. It was impossible to produce an immune serum against organisms of Type III and since each individual race of the organisms belonging in Group IV was apparently distinct, it would be impracticable to produce an immune serum active against any large number of the organisms belonging in this group. At the present time, therefore, the only cases which experimental evidence would lead them to expect might be influenced by immune serum were those caused by organisms of Types I and II. In order to use the serum in these cases intelligently, however, it was necessary that, in each case, the type of organism causing the infection should be determined. An immune serum of Type II could do no possible good if the infection was due to an organism of Type I, and *vice versa*. Unless attention, therefore, was paid to the question of type, both in the preparation of the serum and in its administration, little effect could be expected from the use of antipneumococcus serum in the treatment of pneumonia. An examination of one antipneumococcus serum now on the market had shown it to be entirely free of immune bodies for organisms of Type I and Type II. Its use in treatment was, therefore, valueless. The results so far obtained in the treatment of cases due to the fixed types of pneumococci by the appropriate sera were promising, but much more experience must be obtained before any final judgment could be made.

Wednesday, May 12—Second Day.

Treatment of Poisoning by Bichloride of Mercury.—Drs. Samuel W. Lambert and Henry S. Patterson of New York presented this paper. They divided the symptoms of poisoning into (1) gastrointestinal irritation; (2) acute nephritis with suppression of urine; (3) secondary ulcerative colitis. In the treatment of the first stage, gastric lavage with exhibition of antidote was advised. In the second stage the prolonged use of the continuous rectal absorption by the drip method of solutions of the potassium diuretics; also daily lavage of the stomach and colon until there was a cessation of the secretion of the mercury by the stomach and intestine. The experimental investigations of the secretion of bichloride of mercury from the intestinal tract was given as an indication for the length of the treatment and they advised the application of Vogel's method of demonstrating the presence of mercury in the excreta. They gave the details of cases they had treated.

The Isolation of a Toxic Substance from the Blood of Uremic Patients.—Dr. Nellis B. Foster of New York said that accepting the hypothesis that uremia was a toxemia, the attempt had been made to isolate the specific toxin from the blood of patients with epileptiform uremia. This endeavor had been successful in that a substance, which caused death when injected into small animals, was separated from the blood of the seven cases of uremia studied. Eleven control bloods representing various diseased states other than uremia were also studied but none of these rendered a toxic body. The method of separation excluded, it was believed that errors due to manipulation of unstable protein complexes were present. The final product was recovered.

Intravenous Injection of Dextrose and Depancreatization.—Drs. I. S. Kleiner and S. J. Meltzer of New York presented this communication. When dextrose was injected intravenously into normal animals, it disappeared rapidly from the circulation, and the sugar content of the blood was, in a short time, quite normal again. In previous investigations they found that in depancreatized dogs there was a tendency for the circulation to retain for a longer period a part of the injected dextrose. In recent experiments it was further found that when, with the infusion of dextrose in depancreatized dogs, an emulsion of pancreas was simultaneously injected, the circulation seemed to lose its power to retain the injected dextrose. Finally it was observed and very recently that an injection of a pancreas emulsion in a depancreatized animal was apparently capable of reducing the hyperglycemia to the normal. The evident theoretical importance of these facts should not be discussed there.

Election of Officers.—*President*, Dr. Henry Sewall of Denver, Colo.; *Vice-President*, Dr. George Dock; *Secretary*, Dr. George M. Kober of Washington, D. C.; *Recorder*, Dr. Thomas McCrae of Baltimore, Md.; *Treasurer*, Dr. J. P. Crozier Griffith of Philadelphia; *Councillor*, Dr. Herbert C. Moffitt of San Francisco, Cal.; *Representative in the Executive Committee of the Congress of American Physicians and Surgeons*, Dr. Theodore C. Janeway; *Alternate*, Dr. Richard P. Strong of Manila, P. I.

Magnesium Treatment of Tetanus.—Drs. J. Auer and S. J. Meltzer of New York presented this communication. Of their recent experimental researches only the following facts should be mentioned here which had a practical bearing on the use of the intravenous method. A dog which received 250 to 300 minimal doses of tetanus toxin would probably be on the fourth or the fifth day after the injection in a most severe state of atypical tetanus. When such a dog received intravenously (jugular or ear vein) a 6 per cent. solution of $MgSO_4$ at the rate of about 3 c.c. per minute, in a few minutes a condition might be attained in which many or all the tetanic symptoms were abolished, while the respiration was still fairly satisfactory. The animal was not in danger from the magnesium, even if the respiration was fairly slow and shallow; the respiration improved immediately on discontinuation of the magnesium infusion. When by accident (or purpose) the respiration stopped entirely, an intravenous injection of a few c.c. of a 2 per cent. solution of CaCl, would bring the respiration quickly back and the animal was again out of danger, provided the calcium injection was begun while the heart was still fairly active. The striking inhibitory effect of an intravenous infusion of magnesium was only of a comparatively short duration, on account of the very rapid elimination of the magnesium salt from the circulation; however, the dangerous symptoms might be obviated for a much longer period. On the other hand, the antagonistic action of the calcium salts might be so effective as to bring back quickly every tetanic symptom which existed before the injection of the magnesium salts. Intravenous injection of magnesium had been recently tried in human cases; they would not discuss here the results or the correctness of the methods employed. On the basis of their recent experimental experience they wished, however, to formulate the following statement: The intravenous injection of magnesium salts was an unappropriate method for routine treatment of tetanus, in the first place, because the greatest part of the magnesium might leave the circulation before exerting any action upon the tissues concerned in the production and maintenance of the symptoms of tetanus. It was, however, a very good method to resort to in cases of tetanus manifesting symptoms of an immediately dangerous character, for instance, asphyxia produced by tetanus of the diaphragm or of the laryngeal muscles. The magnesium solution would then be infused until the severe symptoms subsided. It should be discontinued, at any rate, when the respiration became shallow and slow. A syringe containing a 2 per cent. solution of calcium chloride should be kept on hand, to be used immediately in case, by accident, the quantity of the infused magnesium was large enough to suspend the respiration. The injection of the calcium solution should be carried out slowly and continued only until respiration returns. When the procedures were carried out with proper care, they might render indeed an efficient service in cases of immediate need. Weintraud urged the demonstration of their magnesium calcium experiment on rabbits to larger circles of physicians, in order to impress them with the new knowledge acquired of the effects of magnesium and calcium. They might say that experiments on tetanic dogs, as they described them here, ought to make a still greater impression upon the minds of practitioners.

The Hygiene of Aviators.—Dr. George M. Kober of Washington presented this paper. He said that the combined effects of diminished atmospheric pressure and physical exertion in mountain climbing, characterized by palpitation of the heart, dyspnea, headache,

dizziness, faintness, extreme muscular fatigue, nausea, and occasional hemorrhages had been known for some time. These symptoms had been observed in persons not accustomed to a rarified atmosphere in altitudes of 1,500 to 2,000 meters, and higher altitudes naturally intensified the effect. While some of the effects might be due to diminished atmospheric pressure and deficiency of oxygen, muscular exertion and fatigue-toxins doubtless played an important rôle. This was shown by the fact that in the absence of physical exertion, the phenomena of mountain sickness were not observed in balloon flights until an elevation of between 4,000 and 5,000 meters was reached. Petard determined at these elevations a pulse rate of 114 and respiration 44 per minute. Schrötter found that serious symptoms were rarely observed in aeronauts until an elevation of 5,000 meters was reached. Beyond this elevation the pulse at first rapid, became small and irregular with more or less mental depression and the slightest muscular effort, such as unloading a sack of ballast was followed by faintness. Flemming and Steyrer in June, 1911, attained an elevation of 8,910 meters and experienced extremely grave symptoms, such as diminished cardiac and respiratory action, pulse almost imperceptible, cramps and trembling of the muscles, cyanotic countenance and unconsciousness, diminished mental and spinal sensibility symptoms, which urgently called for the use of oxygen inhalations. Most authors agree with Zuntz that, while these symptoms were caused by a deficiency of oxygen, the diminished atmospheric pressure also tended to produce a gaseous distention of the intestines, which impinged upon the diaphragm and thus seriously impeded the respiratory movements. Nausea with occasional vomiting was liable to occur at any elevation if the movement of the airship, in consequence of irregularities of the winds and eddies had become unsteady. The effects of aviation on the ear were characterized by a painful tension, ringing or buzzing noises, and impaired hearing. These phenomena were due to differences in atmospheric pressure and hence were more pronounced during sudden changes in elevation and after a rapid descent. The activity of the violet and ultra violet rays was greatly increased in high elevations, hence sunburns and severe forms of dermatitis were not uncommon, but there was no evidence that the sense of vision was in any way impaired, if protective glasses were worn. The effects of sudden changes in temperature and exposure to extreme cold, fog, rain, or hail and atmospheric electricity constituted hazards and were doubtless apart from mechanical injuries to the apparatus, a frequent cause of accidents. Among other occupational risks should be mentioned the possibility of gas poisoning. Prof. Glaister reported 16 cases of poisoning from arsenireted hydrogen gas, which occurred during the inflation or deflation of the balloon, of from leakage during balloon flights. Since the introduction of motors in dirigible balloons, new elements of danger had been added, such as gasoline explosions, breaks in the propeller, failure to get gasoline into the cylinder during a steep incline, etc. But the accident liability was not as great as generally assumed. According to Flemming in 1,713 balloon flights in Germany, in which 5,786 persons participated. 50 persons were injured; of these four or 0.07 per cent. resulted in death, 24 or 0.41 in serious injuries and 22 in slight injuries. The percentage of fatal injuries was very much greater among aviators. The statistics compiled up to August 7, 1913, showed that 342 aviators had been killed since 1908, when the first man lost his life. It was interesting to note that the physiological effects of diminished atmospheric pressure, upon the lungs, heart, etc., probably because of the more rapid flights of aeroplanes, were observed in very much lower elevations than in balloon ascensions. Cruchet and Moulinièr found at an elevation of 1,000 meters an increase in the blood pressure of between 30 and 40 per cent. with rapid action of the heart. These symptoms were not noted in elevations below 200 meters. None of the flights in that contest exceeded an elevation of 3,000 meters, and symptoms such as palpitation of the heart, earache, vertigo, etc., were especially observed in rapid descents. Flemming reported two cases of unconsciousness which occurred at an elevation of between 100 and 200 meters and which he attributed to the combined influence of cold, flatulent distention of the bowels and passive congestion caused by tight fitting clothing. Instances were cited which indicated that rapid descents after attaining great altitudes were fraught with special danger to the aviator.

The Relationship of the Pathological Histology and the Iodine Compounds of Human Thyroids.—Drs. Louis B. Wilson and Edward C. Kendall of Rochester, Minn., presented this communication and said that by decomposition of thyroid proteins the iodine compounds were separated into two groups. One was insoluble (designated A) and the other was soluble (designated B) in acids. Compound A produced toxic symptoms simulating exophthalmic goiter. In normal thyroids the total iodine was equally divided between "A" and "B" forms. In exophthalmic goiter the most active glands and those with the most diffusible secretion had their total iodine very low and the "A" fraction amounted to only 5 to 10 per cent. of the total. As the degree of activity became less diffusible, the total iodine and the "A" iodine increased to the amount and proportions found in the normal gland.

The Isolation in Crystalline Form of the Iodine-Containing Compound Occurring in the Thyroid: Its Chemical Nature and Physiological Activity.—Dr. Edward C. Kendall of Rochester, Minn., said that the thyroid proteins had been split into simpler products by an alcoholic hydrolysis. From a fraction insoluble in acid a crystalline compound containing 62 per cent. of iodine had been isolated. It appeared to be di-iodo-di-hydroxy-indol. This compound increased the rate and vigor of the pulse, increased metabolism and, in excess, produced symptoms simulating exophthalmic goiter.

The Relationship of Thyrotoxicosis to High Blood Pressure.—Dr. H. S. Plummer of Rochester, Minn., said that a review of the associated clinical and pathological evidence suggesting that thyrotoxicosis of a degree sufficient to produce clinical evidence might in time lead to hypertension.

(To be continued.)

Pathological Society of Philadelphia.

At a stated meeting held April 8 at the Medico-Chirurgical College, Drs. David Riesman and Joseph McFarland presented a specimen of "Carcinoma of the Stomach, with Metastasis of the Liver and Lung." In addition to the classic symptoms of malignant disease of the stomach and liver, jaundice was present. Post-mortem examination disclosed a much enlarged left lobe of the liver, with a fungating mass in the stomach and metatasis to the lungs. There was no obvious involvement of the biliary passages.

Drs. Joseph McFarland and Eugene A. Case presented a collection of "Monsters and Congenital Malformations," formed during the last ten years. There were several examples of acephalus, some associated with meningocele and encephalocele; one of fetus papyraceus; one of intrauterine amputation of extremities; one of congenital defect of digits of hands and feet, a similar condition existing in the father. Dr. McFarland exhibited also a plaster cast duplicating enormous hypertrophy of the three lesser toes and the outer part of one foot from a young man.

Drs. C. J. Stamm, George H. Meeker, and Joseph McFarland presented a communication entitled "An Enterolith from the Human Cecum." The patient presented a palpable mass in the right iliac fossa, in conjunction with symptoms of intestinal obstruction. The condition was looked upon as due to a neoplasm, but x-ray examination following bismuth ingestion by stomach and introduction by rectum disclosed a mass apparently in the bowel surrounded by bismuth. The possibility of the presence of an enterolith was suggested. Renewal of symptoms occurring at a later period, it was found impossible to introduce a tube for the administration of an enema, but digital examination disclosed a large firm obstructing body low down in the rectum, which was finally removed with some difficulty. On chemical examination the formation was found to consist mainly of magnesium phosphate. On inquiry it was learned that the patient had for several years been taking a proprietary preparation of milk of magnesia. The case reported was the only one that could be found in which an enterolith had been recognized and removed without operation.

Dr. Joseph McFarland presented (1) "A Psammosarcoma of the Dura Mater"; (2) "Two Cases of Intestinal Myiasis (a) Caused by Larvæ of Muscidæ and (b) Caused by Larvæ of a Syrphid."

Drs. J. W. Kennedy and Eugene A. Case presented specimens as follows: (1) "Sarcoma and Carcinoma of the Same Breast"; (2) "Sarcoma of the Breast"; (3)

"Congenital Cystic Kidney Removed at Operation"; (4) "Large Carcinoma of the Ovary"; (5) "Beginning Sarcoma in a Uterine Fibroid." Dr. Kennedy presented also an enterolith obtained from a patient who some time previously had had symptoms of perforation of the gall-bladder by calculi with escape into the bowels.

Dr. EUGENE A. CASE exhibited a group of specimens of "Gastric Ulcer."

Dr. J. HAMILTON SMALL exhibited a convenient form of "Easily Extemporized Tube-rack for Wassermann Tests." The device consisted of two wire baskets ordinarily used commercially as receptacles for letters and the like, and slipped one over the other, inverted and provided with a base or floor of wire of finer mesh. The apparatus is quite inexpensive and it has proved its utility practically.

Dr. HERBERT FOX presented a communication entitled "Hodgkin's Disease," representing part of a larger study of the question of diphtheroid microorganisms. He had found such organisms in various forms of adenopathy, but he had been unable to establish any specific relations between the one and the other.

Dr. M. B. HARTZELL presented a communication entitled "Histopathology of Benign Cystic Epithelioma." He showed by lantern slides how in some instances at least this neoplasm originated from the hair-folicles. The cavities present are not true cysts, being merely spaces not lined by epithelium and containing granular detritus.

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

MEDICAL CHEMISTRY AND TOXICOLOGY. The new (4th) Edition, revised. By JAMES W. HOLLAND, M.D., Emeritus Professor of Medical Chemistry and Toxicology, Jefferson Medical College, Philadelphia. Fourth edition, thoroughly revised. Octavo of 678 pages, 116 illustrations. Philadelphia and London: Published by W. B. Saunders Company, 1915. Cloth, $3.00 net.

SCHOOL LAWS OF PENNSYLVANIA. By NATHAN C. SCHAEFFER. Published by Wm. Stanley, Ray, Pa.; 172 pages.

PRACTICAL MEDICINE SERIES. Volume No. 1. By BILLINGS and SALISBURY. Published by Year Book Publishing Co., Chicago. Price, $1.50; 384 pages.

FEDERAL NARCOTIC RECORD BOOK. Published by Abbott Alkaloidal Co., Chicago; 120 pages; price, 25 cents.

AMERICAN SOCIETY OF TROPICAL MEDICINE. Published by Tulane University Press, New Orleans.

DISPENSARY CONTROL OF TUBERCULOSIS. Published by M. B. Brown; 37 pages.

MEDICINE IN CHINA. By The China Medical Commission. Published by University of Chicago Press; 113 pages.

DISEASES OF THE SKIN. By OLIVER S. ORMSBY. Published by Lea & Febiger, Philadelphia and New York. 1128 pages; price, $6.00.

INFECTION AND IMMUNITY. By CHARLES E. SIMON, B.A., M.D. Third edition, revised and enlarged; illustrated. Published by Lea & Febiger. Price, $3.25; 345 pages.

OVERCROWDING AND DEFECTIVE HOUSING IN THE RURAL DISTRICTS. By DR. HARVEY B. BASHORE. Published by John Wiley & Sons, Inc., New York; London: Chapman & Hall, Ltd. First edition, first thousand, 92 pages. Price, $1.00 net.

TRANSACTIONS OF THE AMERICAN CLIMATOLOGICAL ASSOCIATION. Printed for the Association, Philadelphia, 1914. Volume 30; 312 pages.

THE OPERATIVE TREATMENT OF CHRONIC INTESTINAL STASIS. By SIR W. ARBUTHNOT LANE, Bart., M.S. Published by James Nisbet & Company, Ltd., 22 Berners street, W. London, England. Third edition. Price, $4.00; 201 pages.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES. Proceedings of the twenty-fifth annual meeting, held at Chicago, February 17, 1915; 116 pages.

MOTHERCRAFT. By Sarah Comstock. Published by Hearst's International Library Company, 119 West Fortieth street, New York City. Illustrated. 214 pages. Price, $1.00 net.

Therapeutic Hints.

For Acute Radiodermatitis.—Dodd is credited with the following:

℞ Zinc oxide, 30 grams.
Phenol, 2 grams.
Glycerin, 4 grams.
Lime water, 240 grams.

M. et Sig.: For external use.—*Riforma Medica.*

Antipyrine and Aconite in Influenza.—Luigi Maramaldi states that Grasset recommends the administration of these two drugs, the former as a nerve sedative and the latter as a means of combating the initial catarrh of the respiratory tract. The following formula is given:

℞ Antipyrine, 2 grams.
Tincture of aconite, 12 to 15 drops.
Water, 90 grams.
Syrup of orange flowers, 30 grams.

Sig.: One teaspoonful every two hours.—*Giornale Internazionale delle Scienze Mediche.*

Drug Treatment of Albuminuria in Chronic Nephritis.—G. Rummo presents the following prescriptions:

℞ Gallic acid, 1 or 2 grams.

Sig.: This to be taken three times a day.

℞ Strontium lactate, 2 grams.
Distilled water, 120 grams.
Syrup of bitter orange peel, 30 grams.

Sig.: This is the amount to be taken in the course of one day and to be repeated for not more than three days.

℞ Crystallized calcium chloride, ½ to 1 gram.
Distilled water, 120 grams.
Syrup of vanilla or of raspberry, 30 grams.

Sig.: This should be taken in the course of one day.

In the parenchymatous type of nephritis the xanthine derivatives may be used to excite the activity of the renal epithelium. The following may be employed:

℞ Benzoate of sodium.
Theobromine, āā 2 grams.

M. div. in chart. No. vi. Sig.: One every six hours.

Agurin may be given in the daily dose of one gram.

The iodides of sodium and rubidium in conjunction with trinitrin are useful in the interstitial type of nephritis.

℞ Sodium iodide.
Rubidium iodide, āā 15 grams.

Ft. solutio saturata in aqua destillata. Sig.: 10 to 30 drops in water daily and gradually increased.

The nitro-glycerine is administered in doses of 3 drops of a 1 per cent. solution, not exceeding 12 drops in 24 hours.—*Riforma Medica.*

Intramuscular Injections of Insoluble Calcium Salts.—T. Silvestri finds that the insoluble calcium carbonate and phosphate injected intramuscularly are the best of the calcium salts for the prolonged calcification and hypercalcification treatment. For the purpose of an immediate effect, as in hemorrhage, oxalate poisoning, and tetany, the soluble calcium salts are best, in large doses, and preferably by the intravenous route.—*Il Policlinico.*

For Bright's Disease.—Brissemoret is credited with the following prescription:

℞ Gallic acid, 0.8 gram.
Theobromine, 0.7 gram.

M. et div. in pulv., No. iii. Sig.: These are to be taken in the course of one day.—*Riforma Medica.*

CHRONIC PROGRESSIVE POLYARTHRITIS, OR ARTHRITIS DEFORMANS.

WITH A REPORT OF ONE HUNDRED AND FIVE CASES.*

BY SAMUEL W. BOORSTEIN, M.D.,

NEW YORK.

ADJUNCT ATTENDING ORTHOPEDIC SURGEON, MONTEFIORE HOME AND HOSPITAL; CHIEF OF ORTHOPEDIC DEPT., FORDHAM HOSPITAL, O. P. D.; CLINICAL ASSISTANT, ORTHOPEDIC DEPARTMENT, VANDERBILT CLINIC, COLUMBIA UNIVERSITY; ASSISTANT ORTHOPEDIST, MT. SINAI HOSPITAL DISPENSARY.

YOU are probably all interested to a certain extent in arthritis deformans, a disease which disables and cripples so many individuals and finally throws them a burden upon their relatives and the community. As is well known, patients of arthritis deformans are transferred to the orthopedist at a very advanced stage, after all ordinary medications have failed and the deformities are being increased. The general practitioner in disgust refers the patient to the orthopedist, feeling himself relieved of a pressing burden. It would be desirable that the general practitioner should begin the treatment in a proper manner. This will save the patient from getting deformed and crippled. The family physician, by starting the treatment early, will get better results than the orthopedist who is consulted at an advanced stage.

The reason why the family physician frequently fails, is that these cases are improperly diagnosed as rheumatism and treated as such till the typical deformities occur. The patient is then labelled as "an arthritis deformans invalid" or as a sufferer from chronic rheumatism, and is referred to a home for invalids to spend the rest of his life.

I may justly repeat the words of Goldthwait: "It is to these practitioners of medicine, to whom sufferers from joint diseases usually make their first appeal, that these studies are offered." It is my object to point out in this paper the important symptoms, latest etiological findings, and a short survey of the treatment of arthritis deformans, in order to give the general practitioner a clearer comprehension and a better understanding of the disease.

Most of these studies were made at the Montefiore Hospital for Chronic Diseases, where patients can be kept for rather long periods and thus afford the opportunity of careful study and observation.

Nomenclature.—The term "arthritis deformans," which was given to this disease by Virchow in 1869, is an unfortunate word, inexact, meaningless, and confusing. Any joint inflammation, acute or chronic, may lead to deformity and so even tuberculous and syphilitic arthritis might be included, which forms he never intended to be counted in this category. Most of the orthopedists have therefore discontinued the use of this name. The second name by which the general practitioner calls this disease is "rheumatoid arthritis" (a name given to it by Garrod in 1859). This term is still more misleading as this was probably the cause of confounding the ailment with rheumatism and thus led to saturating the sufferers with salicylates. These two diseases, rheumatism and arthritis deformans, can at present with more ease be differentiated and should not be confused. Another name, or rather misnomer, for the same affliction, is "chronic rheumatism." The use of this name is probable due to the fact that while the physician wrongly diagnoses it at first as acute rheumatism, he fails to check it. When the attack has lasted for more than six weeks, the physician as a rule, names it "chronic rheumatism." This term should, according to many authorities, be abolished altogether, as it is doubtful whether there exists such an entity. The term employed by most of the orthopedists and competent internists is "chronic progressive polyarthritis" or "chronic polyarthritis."

Definition.—It is a polyarticular affection beginning either acutely or insidiously, generally involving in a symmetrical manner the distal joints of the fingers and extending to other joints in more or less rapid succession. It is progressive but finally self-limiting, leading however to marked deformities.

Etiology.—(*a*) Sex—More prevalent in women, single more than married. In my series of one hundred and five cases, sixty-five are women.

(*b*) Age—More in adults; in only six cases of this series the disease commenced before twenty.

(*c*) Race—More frequent among white races. I have never seen it in colored people though I am in charge of a clinic where many patients are colored.

(*d*) Occupation and Station in Life—Have no appreciable influence. Those exposed to frequent traumas as dressmakers, etc., are frequently affected. It seems, however, that the frequent traumas are not the real cause but merely influence the kind of deformity. For instance, one of our patients—a dressmaker—used to keep the fingers of the right hand in a straight position while working and at present the ankylosis has stiffened her fingers in that position (Fig. 1). Another patient, a tailor, has the ring and little fingers of his right hand ankylosed in a flexed position for the reason that at work he kept them in that posture. Among the rich, the deformities are of a severer grade for the reason that the wealthy, having servants to attend to their needs, allow their joints to be kept in the easiest position and thus permit their muscles to contract and cause the deformities.

(*e*) Heredity—Has no influence.

(*f*) Fear, Grief, Great Nervous Shocks, and Mental Strain—Seem to have some doubtful influence, perhaps by reducing the power of resistance

*Read before the Medical Society of the Borough of the Bronx, Jan. 13, 1915.

of the patient. In many cases where there was no history of a mental strain or shock—as the patient himself related on first inquiries, subsequent examinations made him find some history of nervous influence. In my experience this happened particularly with patients of a race characterized by a nervous temperament. This shows how one must be careful in interpreting the history of a nervous patient.

(*g*) The Gastrointestinal Tract—Is probably responsible as a predisposing factor and also for keeping up the ailment. It is known that the products absorbed from ordinary bacterial action in the small and large intestines—under pathological conditions (without any new pathogenic bacteria) are causes of joint irritation (Marshal). This gives the class of diseases known as "myositis" and "myalgia," but not arthritis. Ptomaines circulating in the blood may irritate the joints, as proved by the fact that the eradication of ptomaine infection from the gastrointestinal tract has relieved joint pains. This was lately brought to light by the excellent studies started by Sir Arbuthnot Lane on intestinal stasis with the result of the new operation of short circuiting the colon. Visceral displacements causing indigestion have been accompanied by joint disturbances, as emphasized especially by Goldthwait in recent articles. We must not conclude, however, that every patient of polyarthritis has intestinal displacement. Conversely, there are many patients who do have intestinal displacements and show intestinal stasis (as proved with the aid of the latest duodenal methods and *x*-ray studies) who still have no signs of chronic polyarthritis. Elliott, in studying the *x*-ray findings of the intestines in many of the patients included in the series, found deviations from normal in 88 per cent. of the patients examined. He admits, however, that the condition of the intestinal tract cannot be regarded as the sole etiological factor. Many of these abnormalities might have been acquired. "There is however in most of these cases a delayed and sluggish intestinal action which results from a low grade of intestinal musculature and diminished abdominal pressure. The tract is probably an important contributory factor, feeding the malady when the latter has once been localized in the joints. The gastrointestinal tract contains the chief contributing feeder." (Elliott).

(*h*) Ductless Glands—Hyperactivity or disturbed activity of the organs and glands of the body seem frequently to be the cause of joint irritation. This is sometimes noted after pregnancy, in thyroid, pituitary, and pancreatic disturbances. Many of our patients (26) date this disease from the cessation of ovarian activities, *i.e.* the menopause. The arthritis of diabetics may also be classed in this category. The ductless glands surely play some part in disturbed joint function, whether directly or indirectly through general disturbance, but as the physiology of these glands is not clear as yet, we need not consider in detail their pathology.

(*i*) Metabolism—In real progressive polyarthritis, disturbed metabolism plays no part. Much study has been devoted to metabolic disturbances in this disease. Goldthwait and his collaborators found no definite change in calcium, magnesium, and the phosphates. Marshall on the contrary found changes in the amount of creatin, creatinin, and calcium. Pemberton has also made metabolic studies and reports some changes. It seems that the results of all these investigators are not uniform. They probably have not studied the same class of patients. There is, as Nathan has shown, some form which may be classed as distinct "metabolic osteoarthritis," but the number of cases placed in this division is diminishing all the time as our knowledge of the subject is increasing. We can justly predict that in the near future we shall be able, even by the symptoms, to recognize the class of patients in whom metabolic changes are responsible for the disease. In this present article I shall limit myself to such types in which metabolism evidently plays no part.

(*j*) Trauma—In chronic progressive polyarthritis trauma plays a very insignificant rôle as a cause. It perhaps influences the kind of deformity, as has been explained before. There is a class which presents the same pathological changes but is due entirely to trauma. This class is known as "traumatic arthritis," or "arthritis deformans statica" (of Preiser). Recently a theory has been advanced by Preiser of Hamburg, according to which many cases of arthritis deformans are due to an abnormal static condition of the body. The pelvis, thigh, leg, and foot form one static unit and the same applies to the upper extremity. A disturbance in a part of a static unit is felt not only locally but also in all the joints belonging to this unit. There is produced "a pathological incongruence" of the joint surfaces throughout the whole static unit. In such states, the joint structures which are more exposed to trauma have great interference with nutrition, probably from compression of the bloodvessels and nerves supplying them. Gradually the important changes of arthritis deformans appear. This explains the reason for pathological changes in the knee and hip joints and even spine in cases of flat foot and the immediate relief obtained by plates which correct the flat feet. Any mechanical injury to the joints, whether irritation, pressure, overwork, static, or insufficient circulation due to some old injury, as well as muscular weakness and likewise a difference of muscular pull; in short, anything which disturbs the nutrition of a particular joint or set of joints may become a cause of arthritis deformans statica.

The class of arthritis deformans statica can be easily differentiated from the cases of chronic progressive polyarthritis. Only in a few instances cases may be found that are on the border line; the number of these border-line cases is really small and we need not elaborate on them at present.

(*k*) Specific Cause—By far the majority of observers and investigators are now of the opinion that chronic progressive polyarthritis is infectious in nature. The term "infectious" is used here in a general sense, *i.e.*, aside from the cases in which the infection is found in the joint directly, it includes cases where there are minute foci of infection distant from the joint. In these latter cases there is in the joints a continuous bacteriemia of low grade. Under the term "infectious" are also justly included cases which appear to be complications or sequelæ of other infectious diseases, such as arthritis following influenza or scarlet fever.

Let us first consider the secondary infectious cases, *i.e.*, where the causal organism is supposed to be in a distant focus. Among the culpable distant foci are placed: chronic inflammation of paranasal sinuses (including the antrum of Highmore), chronic abscess, chronic bronchitis, chronic ulcerative enteritis, chronic appendicitis, cholecystitis, chronic pyelitis, chronic cystitis, chronic urethritis,

prostatitis, chronic salpingitis, and chronic endometritis. Crow and Soltau, of London, have isolated a staphylococcus from the urine of arthritic patients which they consider to be the main invader of the joints. Thus we see that the blame of arthritis has

Fig. 1.—Case LXXII. A. A. Single, dressmaker. Attack began at 36. Most of the joints ankylosed. Hands show marked wastings of the muscles. Fingers are straight or linear type and ankylosed in that position. This was the position in which she kept her fingers while attending to her work. Notice the marked anæmia. Elbows are ankylosed in that position.

been put on every organ of the body and the organisms causing the diseases of those organs are supposed to be the factors of the arthritis.

There are many experiments recorded in the literature where the contents of a focus of a removed suspected organ or gland (for instance, tonsil) of a patient suffering with chronic progressive polyarthritis were made into an emulsion and injected into the ear of a rabbit or dog. The animal later on developed arthritis. There are also incidents where cultures were made from pus obtained from tooth cavities and vaccines prepared. The patient was watched and in case he developed arthritis, a complement deviation test was made for the organisms of the teeth previously examined with the serum of the blood of the patient. In most of these cases the organisms were found to be the same (Camac).

Now we can turn our attention to the cases of primary infectious arthritis or those in which the bacteria are supposed to be primarily in the joint itself. The organisms found occasionally and directly in the joints of these patients are pneumococcus, gonococcus, streptococcus (of puerperal infection), *Bacillus Welchii*, staphylococcus, and *Streptococcus viridans*. E. C. Rosenow by improved methods has succeeded in isolating peculiar streptococci from the excised lymph glands draining the involved joints, from the contracted and diseased and adjacent muscles, and from excised portions of the diseased capsule of the joint itself. These organisms were isolated from nearly all the cases examined. In some cases the same organism has been isolated at the same time from more or less widely separated regions. Many of these organisms have shown a marked affinity for joints and muscles of dogs and rabbits. In some cases the lesions would closely parallel the condition found in the patient from whom the strain was isolated. From these findings there seems to be little doubt that the bacteria found in the glands draining the joints in chronic progressive polyarthritis are the actual cause of the disease. Parenthetically, your attention may be called to the recent observations by Rosenow and D. J. Davis, that the microorganisms present in any focus may be a changed form of bacteria found in another focus. Thus the organisms of these glands are possibly the changed form of those found in distant foci.

It is hoped that in the near future the orthopedic studies carried out at present with such great zeal will throw enough light to enable us to distinguish between (1) the certainly non-infectious cases, (2) the possibly infectious, (3) the probably infectious, and (4) the demonstrably infectious. An attempt was made to make such a division in this series of cases, but with the means at present available the division is incomplete, and so the cases were divided into groups 1 and 2. Eighty patients were thus classed in group 2.

In concluding the discussion of etiology, we ought not to hesitate to consider these cases of arthritis as infectious, though we are not always able to demonstrate the invading organism. We are placing scarlet fever and measles in the category of acute infectious diseases, though their microbic origin still awaits demonstration. All these patients of polyarthritis on careful inquiry will show fever, leucocytosis, and enlarged lymph nodes, and should be regarded as afflicted with an infectious disease (Barker). Excluding those cases which are distinctly due to trauma and are placed in the class of traumatic arthritis, it has been proved beyond doubt that the predominating etiological factor in chronic progressive polyarthritis is infection.

Pathology.—Differentiation of cases of chronic arthritis according to the pathological and anatomical changes met with in the joints is very complicated. Some have divided the cases according to the part of the joint involved as periarthritis, synovitis, etc., while others have divided them according to the nature of the lesion, *i.e.* degenerative and productive. The great confusion of the pathological

Fig. 2.—Case LIII. A. L. This patient shows the flexion of the knees caused by prolonged sitting in a wheel chair. The knees were later straightened. The spine is also flexed. The fingers show dislocations and ulnar deviations. The right hand shows Charcot's extension type, while the left—the straight type. The skin of the feet was covered with a slight eczema which cleared up later on.

findings is probably due to the fact that most of these cases which have been studied are far advanced. The early cases go to the general practitioner, who may miss the diagnosis and treat them as ordinary rheumatism. Unless the general prac-

titioner is willing to assist the specialist, the study of this disease will not be satisfactory.

I will not burden you with the minute anatomical differentiations. Suffice it to say that almost all the structures of the joints show changes. The joint

Fig. 3.—X-ray of patient shown in Fig. 2. Skiagram shows: (1) Subluxations. (2) Loss of cartilage. (3) Considerable loss of bone and joint destruction. (4) Marked bony outgrowths at the distal ends of the metacarpals, distal and proximalphalanges of thumb. (5) Great irregularity of many of the phalangeal joints with new bone deposit. (6) Spur at the distal and proximal phalanges of thumb. (7) Transparent areas especially marked at the mid-proximal interphalangeal joint of fifth finger. (8) Coalescence of the carpal bones (ankylosis). (9) Many of the interphalangeal joints show bony ankylosis. This radiogram shows clearly that atrophy and hypertrophy go hand in hand. (Courtesy of Dr. Elliott.)

capsule may either shrink or relax, and so we get certain deformities due to this and to muscular contractures with secondary flattening of the bones. There may be thickening of the fibrous tissue, localized edemas, or actual effusion into the joints. The cartilage may be thickened or thinned, smooth and homogeneous, or rough and fibrillated. It may be broken up or divided into layers more or less distinct. The bone itself may show atrophy and absorption, or, on the contrary, may show marked proliferation and hypertrophy with exostosis. Painter and his collaborators tried to divide arthritis deformans into two classes: (1) atrophic—where the bone shows atrophy; and (2) hypertrophic—where new bone growth and exostoses are found. In reality there cannot be so distinct a division. From careful radiographic studies and examination of postmortem specimens of some cases in this series, Dr. Elliott and myself have shown clearly* that atrophy and hypertrophy go hand in hand. We may find in the same patient atrophy in one joint and hypertrophy in another. We may even find both changes in the same joint.

The blood-vessels around the joint show marked proliferation of endothelial cells or a complete plugging of the blood-vessels with a consequent anemic necrosis. Bacteria have been found in these areas of endothelial proliferation. Rosenow states: "We are justified in concluding that the micro-organisms are taken up from the circulation by the endothelial cells which proliferate freely so that eventually the blood supply is reduced or cut off, in consequence of which there result areas of lowered oxygen tension, diminished nutrition, and atrophy." . . . "Such conditions would favor the growth of organisms which on isolation are sensitive to oxygen." Oxhausen, of Berlin, has produced aseptic osteochondritis resembling arthritis deformans by ligating the arteries supplying the joint tissues—thus proving that there may be bacterial emboli which deprive the joint tissues of nourishment. Arterial sclerosis is usually present, which has given rise to the theory that the arterial sclerosis is the primary cause of this disease.

It is to be remarked that among the men who have done excellent work in the pathology of this disease some New York orthopedists—notably Nathan—have played an important part.

Radiographic studies furnish valuable assistance as to the condition of the bones and cartilage as well as the synovial membrane and the soft parts surrounding the joints. We can see at once the presence or absence of: (1) Periarticular swelling; (2) Narrowing of the joint slits; (3) Atrophy or destruction of cartilage; (4) Luxations and subluxations; (5) Erosion of the articular ends of the bone; (6) Rarefaction or condensation of bones; (7) New bone connected with the articular ends entering into

Fig. 4.—Case VII. C. L. Disease began at the age of 50. Patient shows marked anemia. The fingers show the globular shape swelling at the proximal-interphalangeal joints, also the beginning of Charcot's flexion type.

the joint; (8) New bone formation separate from the joint; (9) Distortion of bone due to softening and pressure; (10) Subperiosteal swellings; (11) Fibrous or bony ankylosis; (12) Cysts; (13) Transparent areas; (14) Tophi; (15) Calcified free bodies; (16) Calcification or ossification of ligaments; (17) Lime deposits in bursæ.

Symptoms.– Since we have not gone into details

*The specimens and the radiographic plates were shown at the American Orthopedic Association at the annual meeting in 1911.

of classification, we cannot give a very clear survey of the symptoms characteristic of every class separately. I will, therefore, describe the symptoms in general. As pointed out before, most of the cases

Fig. 5.—Case CIV. A. H. Spine and extremities are involved. The position of the spine, the deformed fingers, the swollen ankles and knees are very clearly shown.

are infectious; we will thus take this class as an example.

The small joints of the fingers and toes, wrists and ankles are first involved. Later the knees and elbows may be attacked. The hips and shoulders frequently escape. The spine in this class under consideration is hardly ever affected. Infrequently only one joint is attacked, when it is called "monoarthritis." The small joints of either both hands or both feet are usually involved symmetrically. In my series of cases, the joints first involved were as follows: fingers, 10; toes, 5; wrists, 40; ankles, 4; knees, 18; elbows, 6; shoulders, 11; hips, 9; spine, 1; mandibular joint, 1; monoarthritic cases, 5.

The disease begins either insidiously or with an acute or subacute stage with fever. Sometimes the patients cannot recollect having had fever, but on careful inquiry such a history can be obtained. Many patients with fever walk around without the slightest suspicion of having an elevated temperature. Of this group, 59 patients gave a distinct history of fever. There is more consistency about the history of swelling at the onset (in seventy-eight cases). Each joint of the proximal row of the interphalangeal joints often presents a fusiform appearance and feels elastic when compressed between the thumb and forefinger of the examiner. Redness may be present, which frequently contributes to the wrong diagnosis of rheumatism (only forty-nine gave a history of redness). Pain is very severe. In the beginning the patient may complain of weakness of the muscles, later on he has crampy sensations, then actual pain. The pain is increased on motion as well as at night. In some patients, particularly in women near the menopause, the onset is very insidious. These old women complain at first of formication, of chilly feelings, and of slight stiffness at the metacarpal phalangeal joints. In almost all patients with infectious arthritis muscular atrophy quickly appears, especially of the interossei. (Figs. 1 and 5.) Contractures and deformities gradually develop. (Figs. 2, 5, 7, 8 and 9.) Many joints become ankylosed, while, on the contrary, some will be very lax and show upon examination a great deal of crepitus. (Case I and Case II.) We cannot predict in advance whether a certain case will end in ankylosis or not, nor has our present knowledge been advanced as to explain the reason of the occurrence of ankylosis in some and laxity in others.

The hand may become deflected ulnarward. The fingers present either the "straight type" of the deformity where they are in a straight position (Fig. 1), or "flexion" or "extension" types of Charcot. In the flexion type, the phalanges of the second row are flexed on the proximal row while the terminal phalanges are hyperextended on those of the second row. The proximal phalanges are flexed on the matacarpals and the carpus upon the forearm. (Figs. 5, 7, 8.) In the extension type the phalanges of the middle row are hyperextended on the proximal row, while those of the distal row are flexed. (Fig. 2.)

Fig. 6.—Same patient of Fig. 5, showing the elbows with marked hypertrophic overgrowths.

Long quiescent periods are the striking feature in this disease. (Case II, for instance, felt perfectly well for nine years, when a second attack set in.)

In children we also find a large spleen, large lymph

glands, leucocytosis, and secondary anemia. This used to be called "Still's disease," but at present it is not placed as a separate class. The findings in Still's disease simply strengthen the theory that this affection is due to chronic infection.

FIG. 7.—Case I (Record Case No. XXI). This picture was taken at the age of 16, on admission to the Montefiore Home. The lifeless expression of the face is somewhat characteristic of this disease. Compare this with Case II. The elbows were contracted in this position. The fingers show the dislocation of the little phalanges on the proximal ones. The carpus is flexed, contour of the wrist joint is absent.

The most characteristic point about chronic polyarthritis is that the disease is self-limiting and very often comes to a standstill even if nothing is done to check it. But, of course, the deformities are present and are increasing, due to the muscular contractions and pressure upon the bones.

Differential Diagnosis.—There are many diseases from which chronic progressive polyarthritis is to be differentiated, but I will mention only the important ones with which it can easily be confused. These are acute rheumatic fever and gout. Acute rheumatic fever is also an acute febrile polyarthritis, but the affection shifts from joint to joint instead of affecting the joints simultaneously and symmetrically as in chronic progressive polyarthritis. The patient has a very high fever, acid perspiration, and marked tenderness of the joint. The swelling is present in the soft tissues rather than in the joint itself. Rheumatic fever is frequently complicated by endocarditis, pericarditis, and chorea. The joint attack usually ends in recovery without residual joint changes. Rheumatic fever in reality has been shown by Paine and Poynton to be an infectious disease and is probably due to a primary infection of the throat with secondary invasion of the blood with the virus and metastatic joint involvement.*

The second disease with which it can be confused is gout. The latter is characterized by a sudden onset, begins first in the feet and more particularly in the big toe. The pain in gout is excruciating and severe. There is no symmetry which is so characteristic in arthritis deformans. Later on the tophi and uratic deposits appear. A metabolism test, where possible, will decide the diagnosis.

Prognosis.—Considering this disease as infectious and self-limiting, we cannot regard the prognosis as unfavorable as formerly held. If the infection is found and cleared, the disease will stop progressing. But even in the far advanced cases a great deal can be done to alleviate the pain, check the disease (?), make the patient more comfortable, and in many cases allow him to walk unassisted and even return to his occupation. The treatments must be carried out patiently and energetically for years and will certainly compensate the efforts. The slow progress of the improvement frequently fatigues the attending physician sooner than the sufferer. These cases are, of course, more efficiently treated in an institution away from home surroundings.

Treatment.—I shall give only a brief survey of the treatment of those cases. The results of the various modes of treatment were concluded from patients treated at the Montefiore Home and Hospital for the last three and a half years and in private practice, but not in clinics with which I am connected. Thus the effects were watched more constantly and carefully. In previous articles (MEDICAL RECORD, February 10 and September 14, 1914) I have reported in full how the treatments are carried out at the Montefiore Home, and I refer the interested reader to those. The accompanying chart shows how the record of patients is made when they enter the orthopedic department. Such record cards can easily be kept even in private practice.

Form of Record Used.

CHRONIC POLYARTHRITIS.

1. Name..... M.F. S.M.W. Age.....
   Date..... Case No.....
2. Address..... Occupation..... Nativity.....
3. Financial Conditions and Hygienic Surroundings....
4. Atmospheric Influences: Exposure to Cold and Wet..
5. Age at onset.....
6. Family History: Rheumatism, Gout or any joint disease .....

FIG. 8.—Case II (Record No. XVI). Taken four months after admission to the Montefiore Home. The face is somewhat similar to Case I. Patient is still confined to chair. The deformities of the fingers are clearly shown to be of Charcot's flexion type. The five deformed fingers are ankylosed in that position.

7. Predisposing Causes: Worry, Anxiety, Mental Strain, Trauma, Static Disturbances, Debilitating Disease, Disturbances in Internal Secretions, Purulent Infections, Gastrointestinal Tract.
8. Exciting Causes: Fecal Infection, Cold, Trauma, Intercurrent Disease.

*The term "rheumatism" has been greatly misused and the orthopedists as well as the pathologists are agitating the abolition of this designation.

9. Initial Symptoms: (*a*) Joints first involved—(*b*) Fever—(*c*) Redness—(*d*) Swelling—(*e*) Pain.
10. Objective Findings: (*a*) Mouth: Teeth, Gums, Tonsils, Tongue—(*b*) Circulatory System: Heart, Blood Vessels (Sclerosis), Blood Pressure, Pulse—(*c*) Lymphatic Glands and Fibrous Nodules, especially near the involved joints—(*d*) Nasal, Eye, Ear and Genitourinary Examination—(*e*) Digestive System: Bismuth Test (if possible) for displacements and Visceroptosis—(*f*) Muscular System: Atrophy, etc.—(*g*) Static disturbances—(*h*) Skin and Appendages: Nails, skin (pigmented or not, glossy or not)—(*i*) Joints Involved, Description, etc. (A Careful Description of All the Involved Joints With Pictures and Measurements—(*j*) Ankylosis (fibrous or bony).
11. Clinical Examinations (if patient is in a hospital)—(*a*) Temperature—(*b*) Blood Count—(*c*) Wassermann—(*d*) Complement Fixation Test—(*e*) Urine Analysis—(*f*) Gastric Analysis—(*g*) Feces Examination—(*h*) Bacteriological Examination of Glands Draining the Joints, etc.—(*i*) X-Ray Findings.

General Treatment.—There should be no routine treatment for all the patients. Each patient with chronic progressive polyarthritis should be investigated carefully. In undertaking the treatment there should be team work between the internist and all the specialists, including dentists. Keeping in mind

Fig. 9.—Case IV (Record No. LXVI). E. C., taken at the age of 37. The swelling of the feet is enormous with marked valgus. The wasting of the muscles is also clearly seen. The knees are ankylosed at that position.

that the etiological factor is infection, we must make a systematic examination of all the orifices of the body: the mouth, teeth, nose, ear, gastrointestinal tract, and genitourinary tract. If there is any suspicion of an offending factor, it should be eliminated. An offending tonsil or bad tooth, etc., should be attended to, but we should not be in haste to conclude that if the bad tooth should be removed, the arthritis would be cured, as many want us to believe. Worry, nervous frets, and all excitements should be prevented. Here we can see the benefit of treating the patient in an institution away from the hustle and bustle of life, as well as from family tenderness. Gastrointestinal indigestion should be corrected. If the patient is in an institution where bismuth radiograms of the intestinal tract can be taken it is advisable to do so and find out whether there is any visceroptosis and evidence of stasis. Visceroptosis can be controlled by belts and corsets and proper support to increase abdominal pressure; but as far as Lane's short-circuiting the colon, one need not be in a hurry, as the results have not been reported as favorable as might have been expected. For constipation mild laxatives might be used. Liquid paraffin will be of benefit here as in all other costive cases. Patients may receive for a short time colonic irrigation and enemas. The functional activity of the liver, pancreas and gastrointestinal secretions must be studied and the cause of the nutritional disturbance be removed. If some deficiency is found, it may be advisable to use pepsin, trypsin and pancreatin. Some observers have found a diminution of hydrochloric acid in the gastric secretion. It may therefore be recommended to give the patient the benefit of hydrochloric acid administration. Parenthetically, it is to be remembered that hydrochloric acid is a good intestinal disinfectant and also kills the mouth organisms, and thus a twofold benefit is obtained from the use of it.

Diet.—Most of these patients suffer severely from anemia. This anemia is probably aggravated by the fact that their attending physicians have forbidden them to consume red meats and thus the anemia has increased. (See Report of Case III and Fig. 4.) The patient must get a full and nutritious diet. Let him eat whatever agrees with his digestion and causes no intestinal fermentation. Urge him to increase his weight by the ingestion of a wholesome amount of digestible food whether or not that food includes meats, starches, sugars, or fat. It is not necessary to remind you of the experiments carried out by von Noorden and his collaborators, which showed clearly that there is no difference between red and white meats. The difference is the way the meats are prepared. For instance, roast meat contains more proteins than soup meat. The increased nutrition will increase the resistance power of the patient and so combat the invading organisms whether they are known or not known.

Local Treatment: (*a*) Immobilization—Should an acute joint be immobilized or not, is a question for careful decision. Some advocate immobilization for a short time, maintaining that this will almost produce a cure. The opponents, on the contrary, show that the joint may become stiff and thus really injured. We must also keep in mind that a plaster of Paris splint, as brought out by Lovett, causes atrophy, and thus immobilization has another harmful effect. We need rather to promote tissue metabolism. While I have used immobilization and have seen the good effects, still I always keep in mind that there are many patients in the Montefiore Hospital who give a distinct history of getting stiff joints after these have been kept in plaster for a few weeks. (See Case III.) According to our findings, it is best to put on only one-half of a plaster splint, which has the benefit of immobilization, allows inspection of the joint, and does not cause atrophy and stiffness. It also gives a chance for the application of other local treatments in addition to rest. The immobilization may be left on from four to six weeks.

(*b*) Active Hyperemia—by means of dry hot air or baking—is very beneficial. Best is to use an electric heated apparatus. The temperature should be brought up to 250°-300° F., and limb kept in there for thirty to forty minutes. Baking has an excellent effect to relieve the pain and can be used in the acute and subacute cases. In the latter or in cases where the active inflammation has subsided, hot air treatment should be followed by massage. The benefits of this active hyperemia can be summarized as follows: (1) It increases the circulation of the joint. (2) The increased circulation causes

a leucocytosis which combats the disease. (3) It favors absorption of chronic exudates. If the general circulation is poor, the baking should be done under careful supervision and not so frequent or prolonged, in order not to debilitate the patient.

(*c*) Bier's Passive Hyperemia—By means of an elastic bandage is of great benefit. We have used it extensively and found that the pain and spasm was relieved, thus allowing better motion and easier massage. It should be started by using it for two or three hours a day, increased gradually, till finally it can be left on for twenty-two hours daily, taking it off for one hour twice a day when the limb is raised to allow return of circulation. It should not be used in case of patients with old sclerosed arteries. Those desiring to get a full conception of the theories and methods of application of the different forms of Bier's hyperemia should consult the special treatise on the subject by Meyer and Schmieden.

(*d*) Electric light baths have been used at the Montefiore Hospital to a great extent. We found that the light together with the heat is of extensive value. The patient should remain in the light bath for about twenty minutes.

(*e*) Massage—This is of greatest value if it can be carried out properly, *i.e.* without causing pain to the patient. As long as there is still redness and inflammation, no massage should be used. When these subside, massage is the strongest combating agent. It improves circulation, prevents deformities and atrophy and corrects any deformity present. The massage should be given only three times a week, and then mostly to the muscles and not much to the joint itself.

(*f*) Exercises, active and passive, with and without Zander's machines, should be started as soon as acute symptoms subside.

(*g*) Various electrical stimulants to the spine and joints do more good psychically than actually. Faradism and galvanism may be of use in the atrophied muscles. We have used also the static and high frequency, which we found of little practical value.

(*h*) Hydrotherapy has been used from time immemorial and is certainly of actual benefit. The steam boxes followed by cold douches are especially useful in cases where many joints are involved.

(*i*) Medications—All forms of salicylates, even aspirin, should be avoided. They upset the digestion and make the condition worse. Only those medications aimed to promote digestion, proper bowel activity, proper circulation and proper character of the blood should be used. It is therefore advisable to give strychnine, arsenic, iron preparations, phosphates and even cod liver oil. Tincture of gelsemium *mv.* (0.3 c.c.) t.i.d. may be used to relieve temporarily severe pain. If intestinal putrefaction is present we may use guaiacol carbonate or hydrochloric acid as intestinal disinfectants. None of the various lithia salts and none of the various laxatives and alkaline waters have any specific action. Radium water, radium baths, and radium emanations are reported by Wachsmann as not having been of service at the Montefiore Home.

(*j*) Glandular extracts of almost all ductless glands of the body have been used. Many report great benefits, but it seems that the good results are reported by the enthusiastic pioneers and are not so favorably reported by others. Among the glands used are: thyroid, parathyroid, thymus, ovarian, testicular, and pituitary. (Some have been administered by mouth, others subcutaneously or intravenously.) I have used all of these, and in my opinion they are of benefit only in those cases where one gland proved to be affected by other symptoms besides the joint findings. If one determines to use any of these he should use it for a very long time before he decides that the patient has not been benefited by it.

(*k*) Vaccine Treatments—Since the "infection theory" has gained so many adherents, the natural turn was for vaccines and we find already a great deal in the literature about the benefit derived from their use. Vaccines have been prepared from the pus pockets around the teeth, nose, nasopharynx, ear, intestinal tract, and genitourinary tract. Crowe and Soltau have isolated a staphylococcus from the urine from which they prepared a vaccine. The use of vaccines from any pus cavity of the body is certainly illogical, as we are not certain that these organisms are really the cause of this particular joint trouble. There may be pyorrhea, otorrhea, vaginal discharge, or what not, but it does not follow that the organisms in any of these are really the cause of the joint lesions. We must also bear in mind Rosenow's findings that the microorganisms present in the lesion may be quite different in character from the germs found in the focus of infection at the same time. The organism might have undergone change. Hasting's work in employing suitable antigens and testing the patient's blood serum by a complement fixation method analogous to the Wassermann test is of great importance in this work. The fixation test is, however, only suggestive but not conclusive, for a person can have a positive pneumococcal or gonococcal test and still have a joint due to another organism, just as one may have a Wassermann positive and still the disease in question may not be due to spirochetes. The only logical use of vaccine is to prepare it not from the focus itself, even if that is known, but from the adjacent lymph glands or tissues. (Rosenow.)

We have not used vaccines in our cases, as we had no facilities as yet for isolating the organisms according to Rosenow's excellent technique (otherwise it is not scientific). We have, however, made arrangements in the Montefiore Home to do this work in the near future and hope to report later on the results of this work.

Prevention of Deformities.—This should be the main aim of the physician. The best method is to steady the joints in the best position while the patients are in bed, and when necessary to employ splints for part of the day and special splints for night time. As soon as the active inflammation has subsided, the patient should be encouraged to use his limbs, but only within the limits of pain. It has been shown that the deformities are of a worse grade in the well-to-do, as these, having assistants to depend on, allow their joints to stay in the most comfortable position and thus marked deformities develop.

In static arthritis deformans the attending physician should correct the causing factor; for instance, if flat feet are the cause of the hip or spine arthritis a plate will correct the foot and bring the set of joints in proper posture.

Correction of Deformities.—If deformities are present at the time when examined, they can be corrected by massage and exercises with and without Zander's apparatus. Surgical interference for correction of the deformities, when the acute inflammations have subsided and likewise for render-

ing the joints more useful, has lately been instituted. The most common operation is brisement forcé (without opening the joint). The cases have to be carefully selected. Elliott and I have broken up even ankylosed deformed fingers and have obtained good results (Cases I and II). Open operations include tenotomies of the contracted muscles, arthrectomies, arthrodesis, insertion of flaps of fascia, cargile membrane or animal membrane. The discussion of these operations does not lie within the scope of this article and I shall therefore omit it.

Analysis of Results of the Treatment.—Considering that these invalids come to the orthopedist at an advanced stage, and also remembering that the report comes from the Montefiore Home, where many of the patients are admitted with the worst deformities possible, some having been sick for ten or fifteen years, we must take this report not as conclusive of the percentage of cure possible, but on the contrary, with an optimistic view, *i.e.* if in advanced cases such reports can be shown in three years' treatments, the outlooks in early cases are still more hopeful.* There are no acute cases included in this report.

Total number of patients treated (of this series), 70.

Number of patients discharged, 22.

Number of patients who have discontinued the treatment of their own accord, 14.

Number of patients still under treatment, 34.

Patients discharged: Total number, 22; cured, 9; improved (as to walking and cessation of pain), 10; not improved, 3; became worse, none.

Patients who discontinued treatment: Total number, 14; improved, 5; not improved, 9; became worse, none.

Patients still under treatment: Total number, 34; improved, 20; not improved as yet, 14.

Conclusions.—1. This disease has no relation at all to rheumatism and antirheumatics should be avoided.

2. The predominating etiological factor is distinctly an infection either in the joint itself or at a distant point.

3. The disease is not dangerous to life and is usually self-limiting, but it leads to marked deformities making the patient a cripple.

4. Prophylaxis in preventing any systemic infection and keeping the digestion and intestinal tract in good condition is essential. Removal of chronic foci anywhere in the body is imperative as a prevention of progressive ill-health.

5. When the disease is present, the place of infection should be sought for and the territory cleared, if possible.

6. General treatment, such as good hygiene, good food, tonics and building up of the patient, is essential to success.

7. Acute joints should be kept at rest.

8. When active symptoms subside, local treatment to the joints, in the form of active and passive hyperemia, hydrotherapy, massage, active and passive exercises, should be administered regularly with great care and patience and kept up for a long time.

9. The occurrence of deformities should be prevented by steadying the joints in proper position at the time of acute infection. When the deformities have already occurred they should be corrected.

*Some patients have received treatments for a short time only while others for two or three years.

10. Patient and energetic work will bring excellent results even in the far advanced cases.

The following are reports of a few illustrative cases:

Case I. (Record Number XXI).—H. H., female, age 17. This is the youngest patient we have in the Home. Her disease began at the age of seven. She gives a distinct history of recurrent attacks of tonsillitis. The disease began with swelling of the right wrist. Within a year and a half all the joints of the body (including the mandibular joints) became affected and many of them ankylosed. The muscles were contracted and thus the joints were deformed in undesirable positions. (Fig. 7.) When she was admitted to the Home three years ago, *i.e.* seven years after the attack started, she presented a very tragic picture: was confined to bed, could neither walk, sit up, lie down, nor use a wheel chair, and even had to be fed. She had no pain except on severe motion as her disease was inactive after the first two years.

Physical examination on admission showed the following: both shoulder joints—marked limitation of motion in all directions. Both elbows in flexed position allowing flexion to 100° and extension to 110°. Supination and pronation—nil; the forearms kept in a position midway between supination and pronation. Hands—flexion of the wrist with marked limitation of motion. Fingers show dislocation of the middle phalanges on the proximal ones. Could not use the fingers. Lower extremities: thighs are flexed on the abdomen and adducted. Both knees in flexed position; extension permitted only to an angle of 105°; flexion to an angle of 135°. Feet: right one is in a position of equinus while the left one is in a position of talipes equinovarus. Active motion in all the joints was almost nil while passively a slight arc of motion was present which was accompanied by pain. Patient could not speak clearly as her mandibular joints were similarly affected.

She received a great deal of mechanical treatment, *i.e.* light baths, baking, Bier's passive hyperemia, massage, and exercises. The digestion was attended to and the bowels regulated and she was put on a good nutritious diet. Her contracted joints were stretched under brisement forcé in several sessions and put in plaster for a few days, then massage and exercises were instituted. Even her contracted fingers were straightened under brisement forcé. Within two months patient could wheel the chair herself. Within six months she walked with crutches for ten or fifteen minutes. At present she can walk for two or three blocks, though she still uses a cane. The physical examination on January 1, 1915, shows that motion of the shoulders is only slightly limited; the elbows can be flexed actively to an angle of 75° and extended to 175°; passively, the forearms can be flexed to an angle of 65°. Fingers are straight and have not contracted, though two and a half years have passed since the operation. She uses them in sewing and writing and has some power of flexion in them. Hips are only slightly flexed on the abdomen, can be extended to angle of 170°, abduction slightly limited; the knees are extended to an angle of 175° with normal flexion. Feet in a normal position. In her temperament she presents a very hopeful appearance. She is still under treatments.

Remarks.—Her recurrent attacks of tonsillitis point to infectious origin. The occurrence of those marked deformities within a year and a half after onset illustrates the bad results of the lack of care in placing the joints in proper position at the time of the acute attack. The disease came to a standstill after two years, showing the self-limitation of this disease. Brisement forcé led to good results when the after treatments were carefully carried out. Brisement forcé of the fingers, which is rather a recent method and can be used only in special quiescent cases, has been resorted to in this case with favorable results. Dr. Elliott has described fully the method we have followed in this particular patient, and I would refer the reader to his recent article in the *New York Medical Journal*, November 14, 1914. The improvement in this case shows that patient and energetic work can produce excellent results even in far advanced cases.

Case II. (Record Number XVI).—M. H., male, age 29, law student. The history of this patient is interesting from an economic standpoint. He had his first attack at the age of 13, which subsided after a year and a half but left him with deformities of the fingers and ankylosis of right elbow. (Fig. 8). He had no trouble whatever for nine years. In 1909, a few months after his graduation from the College of the City of New York, he had a second attack affecting all the joints, accompanied by pain, swelling, redness, and fever. Within a year and a half the patient became a helpless invalid, unable even to use his hands to feed himself. The pain was so severe that he could not sleep. His physical examination on admission to the Montefiore Home in January, 1911, was as follows: Fingers markedly swollen and tender. The right wrist presents a silver fork deformity and partial ankylosis (from the previous attack). The left wrist is contracted and extremely painful. Right elbow is ankylosed in a straight position. The left elbow is swollen and painful. Forearm could not be extended more than an angle of 45°. Supination and pronation in the left elbow, nil. Motion in both shoulders is markedly limited due to muscular spasm but not to ankylosis. The hips are adducted and flexed. The thighs cannot be separated more than five inches. Both knees are swollen and tender and flexed to an angle of 45°. Active motion is nil, but passively the knees can be straightened to a position of 90° and flexed to an angle of 40°. The feet are both everted (turned out), but motion in ankles is free. The specific cause in this case could not be determined, but the fever, enlarged lymph glands and marked intestinal disturbances pointed to an infection. He was put under the service of Dr. Elliott and myself.

The treatments carried out on this patient were in short as follows: A metabolism test was made which showed no deviation from normal. The patient was then put on a good nutritious diet and three to four glasses of buttermilk daily. Special attention was given to his intestinal tract to avoid constipation but enemas were also administered every other day for two or three weeks. The joints received baking followed by very light massage. Bier's passive hyperemia was applied daily for ten to twenty hours. No motion of the joints was allowed. Within two weeks the pain was relieved. Active motion within the limits of pain was then permitted after each massage. Within three weeks patient could feed himself. Within four weeks the knees could be extended to an angle of 135°. A plaster splint was then made for the knees to keep them in that position. This plaster cast was left on during the night to prevent contraction; also for fifteen minutes three times a day while the patient was allowed to walk with crutches. More exercise was permitted daily. In two months patient could walk with one cane only. In three months he was able to shave himself. In six months patient for the first time ventured to go out in the street and one month later he even traveled by car alone. By the end of the year he made a complete recovery from his second attack. The patient was so pleased with his success that he urged us to correct his deformed fingers resulting from his previous attack. Since the disease in these had been quiescent for nine years, we have not hesitated to straighten his fingers by brisement forcé. This, to the best of my knowledge, was the first case where brisement forcé was ever tried on the fingers. Though the pain was severe, the patient followed the after treatments very carefully and obtained very favorable results. It is two and a half years since his fingers were operated on and thus far the deformities have not recurred and the patient has good use of his fingers. He stayed at the Montefiore Home for a year and a half and was discharged, being able to walk without a cane though with a slight limp. He felt well enough to resume his studies and is at present in his last year at law school. All this time he has worked and earned his living while gaining honors at the university. This shows how well he has been feeling for the last two and a half years.

Remarks.—The interval of nine years between the first and second attack in this patient illustrates the statement, made above, that long quiescent periods may pass between the attacks. Though the specific cause has not been discovered, still the attention paid to the diet and intestinal tract and raising the resistance of the patient have succeeded in checking the progress of the disease. The brisement forcé on the fingers was likewise successful in this case, but from our observations in a few cases that we have resorted to this method, only the quiescent cases may thus be treated. This particular case was also mentioned in Dr. Elliott's article on treatment of ankylosed fingers. By patient and energetic work an able and ambitious young man was saved from helpless invalidism and made a useful member of society.

Case III (Record No. LXI).—M. D., female, single, age 24, stenographer and typewriter. The disease began last April, two days after an attack of influenza, thus showing that it was an infection. The right wrist became swollen, red, and very painful. From the beginning there was a great tendency to flexion of the wrist. The disease was diagnosed by her attending physician as rheumatism. She was receiving antirheumatics till her ears were buzzing and her stomach was upset. She was also getting local applications, but all these were of no avail. The pain and swelling were not influenced. She became very anemic due to the restricted diet on which she was kept. After two months "the disease stopped by itself" (I am using her exact language) and she had no more pain. The wrist was flexed to an angle of 160° and there was no motion at all in that joint. The fingers were straight and allowed fair motion actively and passively. There was still swelling of the wrist. Her physician extended the wrist and put on a plaster cast extending from the flexed elbow to the tips of the fingers. The plaster was left on for ten days. When it was removed the wrist and fingers were straight and atrophied and she could not use her fingers at all, presenting almost the appearance of Volkmann's ischemic paralysis. Within a few days her wrist became flexed again and the motion in the fingers remained nil. Her physician then straightened the wrist under anesthesia without putting it in a splint, but as he did not follow carefully the after treatments this became flexed again within a few weeks and the fingers also began to show a tendency to flexion. When she came under my care, in the latter part of August, she presented a wrist flexed to an angle of 160° with no motion actively, but passively an arc of motion of 5° to 10° could be obtained but with pain. The fingers were stiff and the terminal phalanges were slightly flexed on the middle. The skin was glossy and tense, showing marked evidences of atrophy. There was no active motion at all in the fingers. There was no pain at all while the joints were kept at rest. The *x*-ray showed the disease in the carpal bones only with atrophy in all the phalanges. She was put on a good nutritious diet, taking plenty of meat, buttermilk, and cod liver oil. For the wrist and fingers she was ordered baking, massage, and careful exercises. She was allowed to follow her occupation. Within two months patient regained some motion in the thumb, index and middle fingers, but no improvement whatever in the other two fingers except perhaps in the appearance. The wrist became straight and there was even an arc of 5° of motion to extension. She has gained eight pounds in weight. Two months later a brace was ordered for her which allowed the wrist to be slowly and gradually extended but no flexion. She was ordered to wear the brace at night time and for fifteen minutes three or four times a day. The patient herself flexes the little and ring fingers daily. The progress is rather slow, but the patient is so enthusiastic about the results so far that she energetically and punctually carries out all the treatments and there are hopes of fair recovery.

Remarks.—This patient illustrates many important points of my paper. The infectious origin of this attack was clearly shown. The disease stopped by itself, showing the self-limitation of the affection. The antirheumatics have not influenced the pain or swelling. The immobilization done at the improper time and with lack of care has aggravated the deformity and produced the ischemic paralysis. After straightening the wrist under the anesthesia, no after treatments were given, and thus the operation was a complete failure—thus discouraging the patient. No Bier's passive hyperemia was given to this patient for the fear of aggra-

vating the ischemia. The wrist is gradually hyperextended instead of doing this forcibly.

For permission to reproduce the photographs of patients of the Montefiore Home, I am greatly indebted to Dr. S. Wachsmann, the Medical Director of that institution. I also wish to express my gratitude to Dr. G. R. Elliott, attending orthopedist of the institution, in lending me the *x*-ray prints and for his valuable assistance.

1210 Tinton Avenue.

MEDICAL LITERATURE AND ITS PREPARATION.*

By EMIL MAYER, M.D.,

NEW YORK.

LARYNGOLOGIST TO MOUNT SINAI HOSPITAL; FELLOW OF AMERICAN LARYNGOLOGICAL ASSOCIATION; AMERICAN EDITOR, SEMON'S INTERNATIONALES CENTRALBLATT FÜR LARYNGOLOGIE; ABSTRACT EDITOR, AMERICAN LARYNGOLOGICAL ASSOCIATION, ETC.

THE third of a century just passed marks an era of wonderful discoveries in the field of physics, such as the development of the electric light, the telephone, the typewriter, the Roentgen rays, the submarine, and aviation. During this time the advance in medicine has been as remarkable. To mention just a few of these—surgical asepsis; intubation; all of the bacteriological discoveries, notably the diphtheria bacillus and the antitoxin theory; improved methods in diagnosis and in therapy, as salvarsan and pituitrin; painless and bloodless operations and the increased knowledge in sanitation that prevents disease. Two notable instances of these latter are the methods of sanitation in the Japanese army and our own triumph at Panama.

It seems hardly possible that we could have worked and even done fairly well before all these and many more unmentioned boons were given to us for the public weal. For the dissemination of the knowledge of all these advances in medicine we must give great credit to our journals which have also participated in the general advance.

This advance can best be seen if one compares the bound volumes of journals published in the late 80's and those of the present day. In the former a single volume or two at the most represented the year's work, while in the latter from two to four volumes are required for the same amount of time.

Special journals have since sprung up, so that in our own country the number of journals issued monthly is now over two hundred.

Articles prepared for publication in these journals represent not only careful and painstaking medical observations, but also labor of a literary sort no less trying and infinitely more difficult. It is with the hope of making the latter a little less arduous and to aid in the preparation of your future journalistic efforts that I have ventured to address your society, composed exclusively of the younger men in the profession, on the preparation of medical literature.

The presentation of an article for a scientific journal or book is not the easy thing many imagine, and in medicine, at least in our country, no instruction is given on this subject, and it has become a problem each must elaborate for himself. As the future of medicine and the public welfare have always demanded that medical men enter into the literary field, it is remarkable that our medical colleges have thus far neglected so important a part of the conscientious physician's life work.

While not desirous of adding to the heavy burden of the medical student, I would suggest that a few lectures at least should be delivered in our medical schools by qualified instructors on the preparation of medical literature, immediately after graduation and before commencement time. No other studies intervene then, a few lectures only would be required and some credit could be given for attendance. At present the young physician who enters the field of literary medicine has sufficient command of language, the result of his preliminary training, but the demand of the scientific paper is entirely unknown to him. He might learn more rapidly if his early and perhaps faulty contributions were occasionally rejected and the reasons therefor given, and if he had no means of disposing of his work elsewhere; but unfortunately we have such a large number of medical journals eager for matter to fill space that a rejection by one is followed by its prompt acceptance by another and its publication. Rejections, as we know, are very rare.

Editors of medical journals should formulate a plan for some similarity in their methods of acceptance or rejection of manuscript. Then a paper that is full of grammatical errors, tautological, or presented in a slip-shod manner, or whose bibliography is incorrect in presentation or full of errors, would be rejected by each of them, and these journals would soon become known as of the first class and receive communications from the best men in return.

As it is at present, the physician with a message to convey must depend entirely upon his own efforts or be aided by those who have labored hard and earnestly in the field of medical literature, who, while disclaiming perfection in their own endeavors, from many years of experience in writing and in reviewing thousands of medical papers, have learned to appreciate one that is well written and to know how it should be presented.

Preparation.—In the early days of medical practice, when patients are few and far between, I would strongly urge preparation for future medical writing. Remember that to write well is no heaven-born gift, but rather the result of industry, training and application. I would suggest the careful reading of that masterly and readable book by Professor T. Clifford Allbutt, entitled, "Notes on the Composition of a Scientific Paper" (Macmillan Company, 1904); the pamphlets issued by the American Medical Association: "Suggestions to Authors," and "The Bibliographic Style;" as also "Bibliographic Style in Medical Literature," by Mr. Frank Place, assistant in the Library of the New York Academy of Medicine (MEDICAL RECORD, January 25th, 1913, p. 157). Having selected the subject upon which you are to write, mark a large envelope with the name of your subject and place therein everything relative thereto, notes, clippings, case reports, etc.

The Paper.—A well balanced paper is one with an appropriate title, an interesting opening, and a regular method of presentation of cases. It should be free from excess verbiage and with the fewest abbreviations, however, with a bibliography that is very exact but not necessarily complete. It should have a proper conclusion.

The general make-up of a paper should be clean and legible and reasonably free from corrections.

Many a paper has been rejected because of gross

*Read before the Hunterian Society of New York City, November 10, 1914.

carelessness in this regard. With efficient typists, this carelessness is inexcusable.

Papers are often presented for reading before a Medical Society and sent in the same condition for publication, and the transposition is left to the editor. Unnecessary verbiage is the result and many a paper is not read when published because of this fact.

Style.—That combination of language in which felicitous words explain in a clear manner what one intends to convey, namely, style, is not amiss in a scientific discourse. Allbutt states that "the rules of English prose, the English style and the graces of literary art, can as well be employed upon a scientific theme as upon a romantic one."

The command of several languages is of great value, especially when references are sought in journals published abroad. To a very few indeed is it given to be able to write clearly and interestingly in more than one language.

References.—These are best made by yourselves, for much may be learned from the point of view of those who have trod the same fields, and you may also discover and elucidate points omitted by them. It is vitally necessary to have the advantages of an extensive medical library such as we in New York City are proud to possess. Beginning with the last number of the *Index Medicus*, copy carefully the full references on separate slips of paper, leaving space on each for such notes as you may subsequently make when the original is at hand. Working backwards and making use of the catalogue of the Surgeon-General's Library at Washington, also for your purpose, you will either come to the first article upon your subject, or you will find some exhaustive article thereon, to which you may refer as your starting point. Having all your references complete, arrange your slips under appropriate headings so that you will have all the histology, etiology, treatment, etc., in separate packets. Then, and not until then, look up the references, and endeavor to see the originals whenever possible. If the original is not seen by yourself, do not credit the journal not seen by you, but mention the journal from which you quote, stating that it is a quotation taken from the original.

Place on each slip a brief note of the contents of the article referred to. Should it require more, fasten your slip to the notes. Then when you reach the subdivision to which the notes apply you will have a complete reference to the literature of that part of your subject.

As soon as each slip has served its purpose, draw a line through it, but keep it for possible future reference until the article has appeared.

Writing.—The best command of language is obtained by writing rather than by dictation.

The Beginning.—Many writers find their greatest difficulty to lie in the beginning of an article. There is no set rule for the beginning of an article. If such difficulty exists, write the body of the article and then go back to the first page and the opening paragraphs will be more readily written. A felicitous opening will often command close attention, as in the case of a spoken address.

Clearness.—Avoid confusion in your use of terms; the words "case" and "patient" are often used interchangeably. "Case" is an instance of disease, the "patient" is the person affected, not merely a case of disease. The case is reported ended by recovery, but the patient still exists.

The Personal Pronoun.—In the endeavor to eliminate the personal pronoun, one may be too modest and thus appear stilted, confusing the whole subject. There is no doubt whatever as to your meaning when you say, "I saw the patient and three hours later I operated upon him," or "the patient came to my clinic and I operated upon him at once." When the words "the author" or "the writer" are used one must be very explicit.

Grammatical Errors.—Your early training must stand you in good stead here. The scope of this article will not permit a reference to even the most common errors.

Time.—Time should be distinctly defined. The present date should be exactly stated, otherwise "six weeks ago" becomes very indefinite.

Conclusions.—The fewest writers pay attention to this most important rounding out of a paper. Every scientific article should have properly drawn conclusions for several reasons: You do not force the reader to go through all your paper to ascertain what your contentions are; and when you are quoted by the careful abstractor, you will find that he does so in your own words. You have a message to deliver, and what better method can there be than its brief presentation in your own words?

Errors in Bibliography.—I had occasion to enter a protest against such an error but a few months ago. There appeared in one of our medical journals an article on "Vincent's Angina Treated with Salvarsan." The writer of the article stated that "Vincent first recognized the disease in 1898; Bruce also gave a thorough résumé of the disease." The reference to Bruce was given as: "*Lancet*, January 12, 1899." I had been under the impression that I was the first to describe this affection in the English language in 1901, and hence was surprised to learn that Bruce was alleged to have preceded me by two years. I found that there was no issue of the London *Lancet* for January 12, 1899, and that Bruce's article appeared in that journal on July 16, 1904, p. 135, three years after my own publication. As the author who made the misstatement could not see from my letter that he had misstated facts, I wrote to the editor of the journal wherein the error appeared and he promptly published my correction. I stated therein that "our work is often ignored by foreign writers, who claim an alleged inaccessibility of our journals, but we have a right to expect that credit should be given to our own countrymen when the facts warrant and are so easily obtained from our exact medical indices." This is by no means an isolated instance. I have in my possession the reference to an article published this year in one of our best weekly journals. Of the seventeen references, not one is correctly stated. But eleven are referred to in the text, the six other references are added with no indication as to who wrote the article or why they were added. Of the eleven numbered in the body of the article, three were not found in the journals stated and therefore were false. One of the remaining eight mentions the collaboration of two writers, when one of the names does not appear in the original.

Verify References.—Because of the frequency of such errors I have dwelt upon careful attention to the references. They should always be verified and correspond to the numbers in the text.

Description of Proper Reference.—Each reference should contain the name of the writer and his initials, the title of his article, the name of the journal, the year, the volume in Roman letters and the

page. In referring to a book, the title, the number of the edition, the place and year of publication, the name of publisher, and the page are essential.

Title.—While the title heads the subject written about, it is best written after the article is finished and should be attractive and comprehensive as to what is to follow.

Revision.—By the time this part of your work is finished put the paper aside and do not touch it for a week or two. You will then look at it in a more critical way as the work of another and make appropriate corrections.

Typewriting and Directions.—It is now ready to be typewritten. Each page should be numbered, including the title page, and sent in proper order. Double spacing affords room for corrections and these corrections should be in the body of the article and not carried out as in correcting proof, and at least a half inch of space kept on the left of the article. Use quotation marks in referring to other authors and refer to other writers by name. Never roll manuscript; folding is even inadvisable. Send original only, keeping a carbon copy. Neatness is all important. Never send to more than one journal.

Publication.—If simultaneous publications should be deemed necessary, write to the editor and express your desire. It is very unusual for editors to publish articles that are printed elsewhere, but occasionally it may occur without their knowledge. One enterprising colleague wrote an article many years ago and succeeded in publishing it in thirty-five different journals. I have never seen his name in print since that remarkable achievement nor a more disgusted set of editors. Editors often refuse to print an article that has appeared in a foreign country and in a foreign language though it may be of much interest to their readers. Frankness in dealing with editors is only fair and pays in the long run.

Illustrations.—Descriptive legends should accompany all illustrations. If the latter are desired mark them "Return." Drawings in black ink are preferable to photographs. Negatives are of no value and the author's name should be on each illustration.

Proofs.—Proofs are always sent for correction and these should be very carefully read and revised. No detail is too small for your notice—punctuation, spelling, spacing, and paragraphing. Changes of text should be legible and if many changes are made, rewrite the portion as it should be. Note proofreader's remarks or questions, and answer each by correcting or crossing out if it is to stand as you have it. If proofreader's corrections are in black ink, make your corrections in red ink and vice versa, and at the end mark it O.K. and sign your name.

Accuracy.—In spite of all care, errors may furtively enter. Be brief where possible without sacrificing facts. Above all be accurate. Make no statement that you cannot abundantly verify. I have known a whole career to have been wrecked by statements that could not be verified when challenged. Do not consider "any old thing" good enough, because it is to appear in some far away journal. Nothing escapes the eye of the careful abstractor; for the journal of the remotest and smallest city has its place alongside of those from the metropolis in the libraries, and is noticed. When once you have a reputation for accuracy, fairness, and honesty of purpose, your every statement will be accepted no matter how unusual it may seem.

Language.—Simplicity of language, plain and direct, is all important. Quotations in Latin are often incorrect and sound pedantic. Reading the works of the best authors in general literature results in a better command of language, enables you to have a style of your own, and broadens the scope of your knowledge of men and things.

Imitate no one but strengthen and enlarge your ideas, your understanding, and your diction; and finally, do not write for the sake of writing but wait until you have a message to deliver, and then give it your most careful consideration.

With a well rounded out paper you will reread it in subsequent years without embarrassing memories and have the satisfaction of having performed a duty carefully, accurately, and conscientiously; and finally you will have contributed toward the dissemination of medical knowledge and to the honor and glory of a noble profession.

40 East Forty-first Street.

THYROGLOSSAL CYSTS.

REPORT OF CASE.

By CHARLES BERNARD BURKE, M.D.,

ATLANTIC, IA.

Of the various types of tumors of the neck, especially those of congenital origin, the thyroglossal cysts seem to receive the least attention, although they occur with comparative frequency. This report was stimulated by the apparent lack of published descriptions of this condition and the difficulty with which it is diagnosed. Let us first review briefly the embryology of the thyroglossal duct from which these cysts originate.

Embryology.—If we were to examine the floor of the mouth of a five-months' embryo we would find a rhomboidal depression in the median line between the ventral ends of the first and second branchial arches, and from these there rises a dorsal projection of rounded form, known as the tuber impar.

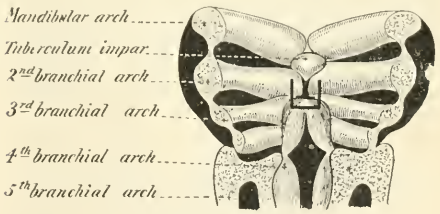

Fig. 1.

Behind this is the deep epithelial (hypoblastic) pit which is the thyroid evagination (thyroid anlage). This grows out, expanding in all directions, especially laterally, to form a stalked vesicle whose lumen becomes obliterated later. Prior to its conversion into a solid epithelial cord the stalk of the vesicle constitutes the thyroglossal duct. The site of its opening into the mouth is marked in the adult by the foramen cecum, which is in reality a short but varying length of the stalk of the thyroid vesicle which fails to solidify and disappear.

After the solidification of the duct the vesicle becomes bilobed and displaced caudally, eventually developing into a broad structure composed of irregular cords of cells. The ultimo-branchial bodies apply themselves to this mass and are, as indicated above, probably enclosed within it. The thyroid

gland belongs, therefore, primarily to the medial region between the first two ventral pharyngeal grooves and becomes displaced caudally until it reaches the position which it occupies in full-term fetus. This explains why the thyroglossal duct,

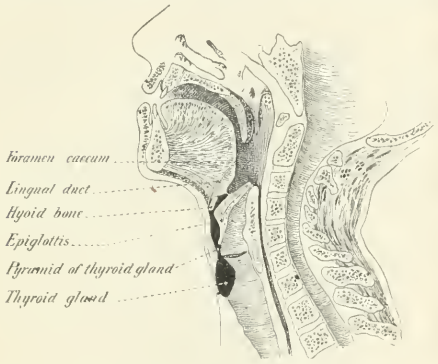

Fig. 2.

when it persists, usually runs posterior to or through the hyoid bone and why it is so difficult to remove it surgically.

It may be seen from the above that since thyroglossal cysts occur in the thyroglossal duct, they may be found any place in the median line between the foramen cecum and the isthmus of the thyroid gland. They may occur at any age and seem to be more frequently seen in the male than in the female. They are usually firmly fixed to the hyoid bone, just above or just below it. They are classified according to their location; those between the foramen cecum and the hyoid bone are called sublingual cysts and those below the hyoid bone, subhyoid cysts.

Diagnosis.—They grow slowly, are usually painless, and they may rupture through the skin and form a median fistula which discharges a mucus-like material. They impart a fluctuating sensation to the palpating fingers. They are freely movable from side to side, but are firmly fixed when an attempt is made to draw them forward. They do not impart a shadow when strong light is applied to

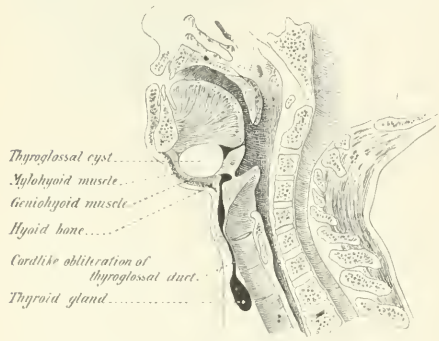

Fig. 3.

one side of the neck while the other is examined in a dark room.

They are to be differentiated from: (1) dermoid cysts, which are frequently found in this location, and (2) sebaceous cysts; the latter, however, are located in the skin and do not appear before puberty. The prognosis depends upon the completeness with which they are removed. A tumor or cyst of the thyroidossal duct requires excision. They are usually firmly fixed to the hyoid bone and must be

Fig. 4.

completely removed, even if it is necessary to split the bone to accomplish it. If any portion of the cyst wall is left a recurrence may be expected.

Mrs. R. N., age 26. Seven years prior to operation she noticed a slight enlargement under her chin but said she paid no attention to it thinking she was getting a double chin, commonly seen in fat people. It gradually enlarged without pain or discomfort, for six years, when it began to interfere with deglutition and speech. She consulted in all five different doctors, and each had a different diagnosis. The last one she called on said that it could be cured with *x*-ray treatments, but after taking these treatments over a long period of time she became discouraged because there was no apparent improvement. The enlargement or cyst as may be seen from accompanying illustration, was located in the median line just above the hyoid bone, to which it was firmly attached and from which it was removed with difficulty.

The following test may be of some value: Take an ordinary Bellevue head lamp and apply it firmly to one side of the neck and examine the tumor mass from opposite side, having the patient in a dark room. In this case the neck had a clear pink color not showing any shadow as would be expected from a solid tumor or dermoid cyst.

DOUBLE CLUB FOOT IN TWINS.

(From the Orthopedic Clinic of Stanford University.)

By LEONARD W. ELY, M.D.,

SAN FRANCISCO, CAL.

The two patients, three weeks old, were brought to the Orthopedic Clinic by their mother with the following history:

The father is an Italian, the mother an English woman. No history of deformity appears in the parents' families. These are the first children of the mother. They are both girls and are supposed to have been 7 month babies, weighing at birth 6½ and 5½ pounds. The labor was an easy one, and both children were born with vertex presentation. The deformity was observed immediately after birth. The examination showed two babies slightly smaller than the average. Both had well marked

double club foot. The deformity was quite rigid in all four feet. No other deformities were present. Neither child showed any evidence of spina bifida. The accompanying photograph shows the deformity

well. The occurrence of double club foot in twins is unique.

The treatment consists of gradual reduction by plaster of Paris bandages.

RADIUM THERAPEUTICS OTHERWISE THAN FOR MALIGNANCY.*

By JOSEPH B. BISSELL, M.D.,

NEW YORK.

IN response to the request of your president it gives me pleasure to present to you some patients who have been treated and cured by means of radium applications. These were not cases of malignant disease, and it is interesting to realize that radium is available to relieve other than cancerous conditions.

CASE I.—Mr. J. McC., 43 years of age, has always been a healthy, robust man, working hard as a laborer. A few days before coming into the hospital he infected his thumb while opening oysters. He states that a piece of oyster shell penetrated under his thumb nail, making a very painful wound. This soon became red and swollen, and the pain and tenderness extended up his arm. On entering my service at Bellevue he presented a typical picture of infection of the thumb and forearm, with an involvement of the metacarpophalangeal joint and ostitis of the bones entering into this joint of the right thumb. There was a severe cellulitis of the surrounding soft parts with abscesses extending up the arm. The disease was treated in the usual way by incisions, irrigations, and wet dressings. At the end of three weeks there were several profusely discharging sinuses about the thenar eminence, and bare bone was felt through these sinuses. An *x*-ray picture taken at this time, which I now show you, disclosed a badly disorganized joint, and a necrosis of both bones. It was decided by the patient and myself that the best thing to do to get him well quickly was to remove the thumb. Before doing so, however, I decided to try the effect of short time radium applications into the sinuses. Thirty milligrams of radium in three different tubes were inserted into the sinuses leading to the joint. These insertions were made on four different occasions, and the radium was allowed to remain in the sinuses ten minutes each time. The applications were made four or five days apart. Immediately following the first application the discharge decreased, the sinuses contracted, the swelling began to lessen in amount, and at the end of the third application only one sinus remained large enough to insert a tube into. The other two tubes were therefore placed on the outside of the affected part and for the fifth and last application all three tubes were so applied. At the end of two weeks from the beginning of this treatment the infection had entirely disappeared, the thumb was again a solid part of the hand and the patient was able to use it as you see now. Here is a remarkable change from a soft, jelly-like mass of broken down tissues with a foul odor, discharging sinuses, and a painful and useless hand to what is as you see a perfectly comfortable and available organ, although somewhat scarred and stiffened. He uses the thumb now for every purpose for which it was designed. At no time was any dead bone removed or did any come away, although the *x*-ray picture shows its presence.

CASE II.—Another patient, a woman, 35 years old, who suffered from an infection of the foot, due to a compound fracture of the second phalanx of the second toe of her right foot. The injury was so severe and the infection so deep that the toe was amputated at the metatarsophalangeal joint; the infection continued however, and involved the metatarsal bone. At the end of several weeks a sinus remained, extending from the upper surface of the foot to the diseased bone with no tendency to healing. Into this sinus, and alongside the bone, a tube containing ten milligrams of radium was inserted and allowed to remain for twenty minutes. Pain, swelling and discharge at once began to disappear, and the sinus to grow smaller, so much so that the next insertion of the tube five days later was quite difficult and almost unnecessary. A week after the original application the patient had entirely recovered and walks, as you may see, without a limp or any evidence of having so recently convalesced from a severe infection.

CASE III.—Mr. L. M., 28 years old, clerk, has been suffering for the past three years from diabetes. Early in December, 1914, he first noticed pain and swelling of the under surface of the base of the second toe. This gradually became localized into an abscess at this point followed by an ostitis and necrosis of the head of the second metatarsal bone and the adjoining phalanx. February 10th a sinus remaining, and no improvement having taken place in the foot which was now quite decidedly involved in a secondary cellulitis and lymphangitis, the sinus was washed out with a weak solution of radium and 10 milligrams of radium protected by a silver capsule and rubber screen applied for half an hour. Three days later the discharge was much less profuse, and 35 milligrams of radium were applied to this region, 10 milligrams of radium being applied as before into the sinus. Five days later the sinus was so nearly healed that it was impossible to insert the radium capsule. The same quantity of radium was applied in divided doses on both surfaces of the toe and foot near the sinus. Ten days after the first application of radium there were no further evidences of inflammation of the foot or bone, and the patient was out of bed and walking with only a slight limp. His diabetes had been treated dietetically during this surgical attention, and his general improvement was also marked. He was discharged March 10 free from sugar and apparently medically and surgically well.

CASE IV.—Another case, Mary H., 49 years old, had been treated by me seven years before the present trouble. At that time I had removed a cartilaginous and badly lacerated fibrous cervix uteri. The patient had had no symptoms of any trouble in this respect until six months ago, when she presented herself to my friend, Dr. Baldwin, of this city, because of constant uterine hemorrhage. He treated this with varying degree of success for several months. About six months ago I saw her and put her under an anesthetic for an examination and removal of a piece of the bleeding tissue for microscopical examination. On examination under ether blood could be seen oozing from the stump of the uterus. Curettage was performed rather unsatisfactorily, 75 milligrams of radium was then applied against the curetted point and kept in place by packing for eighteen hours. The packing was removed, irrigations advised, and no further treatment applied. The radium was applied June 25, 1914. There has been no return of bleeding up to date. Following the radium insertion the patient had a very severe rectal and vesical tenesmus lasting several weeks, and accompanied by rather profuse and painful vaginal discharge. This I assume was due to a radium burn. The radium in this instance was screened off by a half millimeter of lead and silver, reinforced by another half millimeter of rubber and adhesive plaster covering.

CASE V.—This lady, 25 years old, unmarried, had been operated upon some six weeks before February 1, 1915, for gallstones. Following their removal the gall-bladder was drained and the biliary sinus is still open. She is suffering now from small abscesses in either axilla. These abscesses are not large,

*Read in part at the meeting of the City Hospital Alumni, March 17, 1915.

about the size of a small grape, and superficial in depth. They were slow in healing after opening and in that way troubled her considerably. A ten milligram of radium capsule was placed in the cavity of each abscess for five minutes. The cavity at once began to dry up and in forty-eight hours every abscess so treated closed and remained closed. New abscesses appearing were opened widely, and a ten-milligram radium capsule applied to the cavity for five minutes, with the result that the lesions all healed very rapidly. A course of four or five days of this treatment cured the patient of her tendency to suppuration in this region. No attempt was made to treat the biliary sinus with radium and this finally closed after several weeks' treatment.

Case VI.—Another case of totally different nature is offered for consideration. Mrs. H., 44 years old, came into the hospital, December 13, 1914, appearing to be in the last stages of pernicious anemia. Her blood picture was as follows: Reds, 1,207,000; whites, 4,400; hemaglobin, 32 per cent.; eosinophiles, 3. Appetite poor, sleep badly broken, suffering from considerable dyspnea. Temperature 100°, pulse 120. Physical examination shows slightly enlarged spleen and great emaciation, weight being about 72 lbs. in a patient of five feet, two and one-half inches. She has a well marked hemic murmur. No signs of any disease of other organs. Repeated examinations of the contents of the bowels showed no ova or any evidences of hookworm or any other intestinal disease despite her marked eosinophilia, which at times during her treatment was as high as 14 per cent. This patient was seen by many of my colleagues who concurred in the belief that she was suffering from pernicious anemia. Before coming under my care, and since, she has been treated very thoroughly with various iron tonics and other medication, by dietetic measures, by rest and change of climate and environment, by various sera, and recently by long-continued intermuscular injections of caccodylate of soda. She grew steadily worse, her anemia increasing as well as her weakness until her red blood count was reduced to 1,080,000 and her hemoglobin to 27 per cent. This was early in January, 1915. January 6 she was given intravenously 100 micrograms of radium solution. This was repeated in eight days. Following this every second day she received an intermuscular injection of one-half a microgram of radium in solution for two weeks and thereafter every third or fourth day for six weeks. The first week in February the patient began to show marked signs of improvement which steadily continued. She now weighs about 100 lbs., has improved in appearance and color, is out of bed and out of doors, eats and sleeps well, and is entirely a different woman in every way. Her hemoglobin is 75 per cent. and her red cells are 3,850,000. The radium injections have been left off for the past two weeks. She has had no medication whatever since March 10.

These few cases are presented because of the striking results obtained by rather uncommon ways of using radium. Attention is particularly called to the interesting effect of the application of radium in streptococcic bone infection. The cure of pernicious anemia by intravenous injection and intermuscular injection of solutions of radium as seems to be the result in the last case would suggest new opportunities for treatment in this usually fatal disease.

46 West Fifty-fifth Street.

PITUITARY GLAND IN GONORRHEAL ARTHRITIS.

A REPORT OF THREE CONSECUTIVE CASES.

By MARY SUTTON MACY, M.D.,

NEW YORK.

NEUROLOGIST, DEMILT DISPENSARY.

Gonorrheal arthritis occurs in probably 1 per cent. of cases of urethral gonorrhea (Keyes) as an expression of the generalized infection, and as a rule the severity of the inflammatory process is not as great as in other forms of septic arthritis.

Nathan (*New York Medical Journal*, March 16, 1907) insists that gonorrheal arthritis is never genuinely chronic though it may be recurrent. The cases which are called chronic, he says, "are those in which the initial acute inflammation has left behind bands of adhesion or other structural change in the synovial membrane. . . . These changes, unless treated mechanically or by operation, are permanent." Keyes says that "this is not strictly true as is shown by the cures resulting from serum and toxin treatment."

Treatment of gonorrheal arthritis by Bier's hyperemic damming and other forms of producing hyperemia, such for example as baking, massage, and high frequency currents have their advocates. The more general acceptance of the value of autogenous vaccines and of sera must never be overlooked in handling these cases, and, if possible, the method reported by Titus (Medical Record, July 25, 1908), who uses a vacuum electrode, introduced into the rectum, for the destructive effect on the bacteria exerted by the actinic action of the high frequency rays, should be given a trial, as it is very essential, if permanent results are to follow, to disinfect effectively the genitourinary canal. Dardel (Medical Record, Jan. 25, 1913) states: "From the general viewpoint we must disinfect the genitourinary canal, and it should be borne in mind that many of these obstinate cases are consequent upon slight uterine affections or chronic urethroprostatitis. The local treatment of these affections is even more important than that of the inflamed joints. On the other hand, Leopold Levi, Parnac, and Papiman and Viola have published notes of cases in which very marked improvement followed a course of thyroid treatment."

Wallace and Child published (Medical Record, Oct. 4, 1913) a preliminary report on the "extract of pituitary body of the ox in the treatment of rheumatic arthritis," in which they state: "All of these cases showed improvement in the general conditions, in the pains, swellings, and the motions of the joints affected, and in the effect on the bowels." They gave a preparation of fresh gland in sterile physiological salt solution intramuscularly, and as it is known that the active principles diffuse but slowly through animal membranes and that pituitary extracts are absorbed slowly from the stomach and destroyed by the pancreatic digestion, some other form of administration than either of these was sought when pituitary treatment was considered for the cases herewith reported.

These three cases of gonorrheal arthritis occurred in my dispensary class, being referred to me for electrical treatment from other departments or dispensaries, not equipped with electrical apparatus. Each case had, at the time it was referred to me, been under autogenous vaccine treatment, as well as local antiseptic treatment for the infection of the genitourinary tract. The arthritis had been of some months standing and had not yielded at all or in very mild degree to the vaccines nor to hyperemic treatments. The genitourinary examinations having shown repeated "sterile" specimens and the arthritis still being persistent, the cases were referred to me for high frequency treatment of the arthritic joints.

Case I.—Mrs. G. had suffered for four months from a gonorrheal inflammation of all the digital joints of the left hand, the thumb and index finger excepted, and recently—two weeks before beginning electric treatment—the joints of the ring and middle finger of the

right hand had shown a mild inflammation. Treatment with high frequency current resulted in slight improvement in the pain, but had no appreciable influence upon the swelling or motor ability of the fingers. After two weeks the patient was given thyroid gland, gr. j., t.i.d. on the indication of her general symptoms, with noticeable improvement in the texture of skin, relief from the great sensitiveness to cold, and improvement of the constipation, but still no effect upon the arthritic joints. The high frequency was continued during thyroid medication, at the end of twelve weeks electric treatment—during ten of which thyroid was administered—a tablet of pituitary gland substance, gr. j., was triturated, and then the powder ionized into the joints by the high frequency spark. At the next visit, *i.e.* after one treatment of this ionized pituitary, the patient expressed herself as "feeling much better" and demonstrated her improvement by showing decreased swelling and ability to move the fingers in some slight degree. At the second treatment the error was made of triturating the pituitary in glycerin, thinking it would be easier to spread smoothly over the surface of the joints. The effect was to produce a skin burn on two fingers—but not on the others—which was very obstinate in healing. Later treatments avoided such complications by using the powdered substance only, not more than 1 gram being used at any treatment. Within ten days after beginning this treatment all inflammation had disappeared and motion had returned without contracture of the tendons or other disability. Treatments were discontinued after two weeks and in the subsequent three months there has been no return of the symptoms—nor of the previous thyroid symptoms, which disappeared simultaneously—though the patient reported for some time because of the burn and was accidentally encountered a few days ago. Previous to discharge other genitourinary specimens were sterile.

Case II.—Mrs. R. Came with similar history of gonorrheal arthritis of right elbow persisting for six months though sterile genitourinary specimens had been obtained for three months, and no improvement had followed vaccine, hyperemic, or massage treatments, and very slight improvement had resulted from thyroid therapy. As she came to me after the beginning of Mrs. G.'s improvement under pituitary, I did not linger long over preliminary high frequency treatments. She showed no appreciable effect at the end of a week, so the pituitary was begun then, and at the end of the first week of pituitary ionization the pain had disappeared. The amount of pituitary used was increased to 2 grains and improvement became marked and progressive. In six weeks she was discharged with perfect motion, no appreciable inflammation and no pain; the amount of pituitary was reduced again to grain at the end of the fourth week. No internal medication was given during the treatments and no burns resulted from the ionizing of the dry triturate.

Case III.—C. L., a lad of ten years, referred from a children's clinic, with an arthritic knee and ankle of the left side. History of gonorrhea but sterile specimen for two months, and no improvement in the joint condition which had persisted for three months. Pituitary was used at once, on the evidence of the other two cases, and cure resulted, uneventfully, in six weeks.

I am at a loss to explain the reason for this action of pituitary in these cases. The effects on the blood pressure were those generally noted by observers, *i.e.* a preliminary slight rise and a coincident diuresis, but neither of these conditions persisted to the end of the treatments. In the case of Mrs. G. thyroid medication was stopped when the ionization of pituitary began but the hypothyroidal symptoms continued to improve and disappeared entirely simultaneously with the arthritis. Mrs. R. had no marked symptoms of thyroid insufficiency when she came to me, and I discontinued the use of the thyroid on beginning the pituitary treatment.

If the explanation of the reduction of the inflammatory process by the pituitary treatment is one of increased metabolism, why was the thyroid medication not more effective in the two adult cases? On the other hand it seems perhaps possible that the pituitary did produce some increased metabolic effect—or at least catabolic effect—as in all three cases the preliminary diuresis was accompanied by increase in transpiration and perspiration and increased intestinal activity as evidenced by the complete disappearance of constipation, and, in Mrs. R. and the boy, the appearance of a mild diarrhea. Might this be interpreted as interaction of the pituitary on the thyroid mechanism? But again, if so, why did not the thyroid therapy have more preliminary effect?

The above report is submitted with a full recognition of the fact that the cases are too few to be conclusive evidence, but, as the results have been so unusual and so prompt, it seemed to me worth reporting in order that the method may be tested by other observers and possibly some further definite and reliable data obtained and a reasonable theory evolved to explain the pituitary action.

101 West Eightieth Street.

DIAGNOSIS AND CONSERVATIVE TREATMENT OF INFLAMMATION OF THE ACCESSORY SINUSES OF THE NOSE.

By J. L. MAYBAUM, M.D.,

NEW YORK.

ASSISTANT SURGEON NOSE AND THROAT DEPT., POST-GRADUATE HOSPITAL, O.P.D.; CLINICAL ASSISTANT, EAR DEPT., MANHATTAN EYE, EAR, AND THROAT HOSPITAL.

In considering this important subject, no endeavor will be made to enter upon the detailed and intricate methods of diagnosis and treatment, such as are only at the command of the trained rhinologist; rather an effort will be made to confine myself to the simpler diagnostic and therapeutic procedures, many of which can readily be employed by the general practitioner. The importance of these cases to the general practitioner can be fully appreciated when one recognizes the fact that acute sinusitis, involving one or more sinuses, is a frequent accompanying condition of severe acute coryza, influenza, and other infectious diseases, while under ordinary conditions such acute inflammatory affections of the sinuses heal spontaneously, if unrecognized or improperly treated, the mucous membrane lining these cavities undergoes chronic inflammatory and degenerative changes, with the production of a diversity of symptoms and signs often difficult to eradicate except by the use of radical operative measures.

For a proper comprehension of the diagnosis of sinusitis, a brief anatomical consideration of the subject is necessary. The clinical classification of Hajek, brought to our attention twenty years ago in his classical work on Diseases of Accessory Nasal Sinuses, is still adhered to with but slight modification by rhinologists the world over. Hajek divides the sinuses into two groups. To the first group, which he designates Series I, belong the frontal, anterior, ethmoidal, and maxillary sinuses. The ostium of each of these opens into the middle meatus, *i.e.* in the space between the middle and inferior turbinates. Inflammatory disease of one or more of the sinuses of this group reveals itself by the accumulation of purulent discharge in the middle meatus. In Series II are included the posterior ethmoidal cells with orifice opening into the posterior part of the superior meatus (between superior and middle turbinates). The sphenoidal sinus, also included in this group, has its orifice located in the anterior wall of the sinus usually

near the roof of the cavity. Diagnostic of inflammation or sinusitis of the second group is the presence of purulent discharge in the olfactory space, that is in the space between the septum and the medial surface of the middle turbinate. A post-rhinoscopic examination showing purulent secretion on top of the posterior end of the middle turbinate, together with the presence of crusts and secretion in the vault of the epipharynx, is suspicious of posterior ethmoidal and sphenoidal sinusitis. Ordinarily both of these sinuses are simultaneously affected, with symptoms and signs so similar that a differential diagnosis is impracticable.

In arriving at a diagnosis of inflammation of the accessory sinuses, one must not overlook the fact that a single sinus is rarely diseased, two or more sinuses being commonly affected at the same time. I observed not a few cases at Halle's Clinic in Berlin, of long-standing sinus disease in which a unilateral involvement of all the sinuses was present—pansinusitis. As an exception to the above, it may be remarked that the maxillary sinus may alone be affected in about 25 per cent. of cases, this phenomenon being explained on the ground that in the above proportion of cases inflammation of this sinus is attributable to infection from the teeth (bicuspid teeth and first molars). In such cases the roots of these teeth are either in close relation to the floor of the maxillary sinus or actually penetrate the sinus mucosa. Inflammation of the other sinuses, including a large proportion of cases of maxillary sinusitis, have a common source of infection, that is the nasal mucosa. A few general considerations will therefore be of greater importance to the proper comprehension of the diagnosis of these conditions, rather than a detailed description of the symptoms resulting from inflammation of individual sinuses.

Every unilateral chronic discharge of pus from the nose should be regarded as suspicious of chronic sinusitis. Furthermore, the discharge of pus in these cases is marked by a definite periodicity, that is, it usually appears in the morning. The discharge, accumulating in the diseased cavity during the night, flows through the ostia more or less freely as soon as the patient assumes the upright position. The latter fact is particularly applicable to the frontal sinus, inasmuch as the orifice of this sinus is located in the floor, that is the lowest level of the sinus. To a lesser extent this fact can be applied to the sphenoidal and maxillary sinus, the ostia in these sinuses being located at a higher level above the floor of the sinus.

Headache is a frequent symptom of sinusitis, the location depending on the sinus or sinuses involved. In sphenoidal disease occipital headache is a common symptom. Formerly supraorbital or infraorbital neuralgia was frequently diagnosed although frontal or maxillary disease was the causative factor. In true supraorbital neuralgia, the symptoms are paroxysmal in character, occur suddenly, radiating to the area corresponding to the anatomical distribution of the nerve. Pressure continued for some time causes lessening of pain. Pain due to frontal sinusitis is delimited by the size of the sinus, and is mild at first, increasing in intensity and disappearing slowly. Pressure causes an accentuation of pain. The pain in frontal sinusitis is complained of especially soon after rising, diminishing in intensity or even disappearing towards evening. Edema of the soft part overlying the affected sinus frequently occurs.

By means of anterior rhinoscopy, one can arrive at the decision not only that the sinuses are involved, but the particular group to which the sinuses belong may be diagnosticated with a fair degree of accuracy. So small and concealed are the ostia of the different sinuses that a direct inspection of them is rendered impossible. The presence of pus in the middle meatus, as previously mentioned, is indicative of maxillary, frontal, or anterior ethmoidal sinusitis. Should pus be seen in the olfactory space, that is in the cleft between the medial surface of the middle turbinate and septum, suspicion would be directed to the posterior ethmoidal and sphenoidal sinuses. Reappearance of pus immediately or soon after being wiped away from the middle meatus would be a point in favor of diagnosis of frontal sinusitis. After lavage of maxillary sinus, pus will not reappear in the middle meatus for a considerable time, *i.e.* half an hour or more. In inflammatory affection of this sinus, the explanation of this fact is reached on an anatomical basis, that is, the larger size of this cavity and the location of its opening at almost the highest level. Before arriving at any conclusion regarding the diagnostic value of the location of purulent secretion in the nose, a careful and thorough irrigation of the nasal cavity with saline solution should be the first procedure, followed by the application of a 5 per cent. cocaine solution in 1-2000 adrenalin solution, in order to bring the respective areas into better view.

As an aid to diagnosis and therapeusis of sinus disease, the utilization of negative pressure in the nasal cavity, by means of appropriate suction apparatus is to be recommended. By this means the presence of pus may be demonstrated in the middle meatus or olfactory space, the nasal cavity having previously been thoroughly cleansed with saline solution.

Transillumination of the frontal or maxillary sinuses offers an excellent although not infallible means of reaching a conclusion as to the presence or absence of fluid in these cavities. This procedure is less satisfactory in determining the presence of fluid in frontal than in maxillary sinusitis, because the frontal sinus varies so much in size and conformity that a definite conclusion cannot be reached by a somewhat darker area of the affected side. The application of this method consists in placing a small electric lamp in such a position that the rays of light will penetrate the sinus, thus permitting one to obtain an idea of the internal condition by the character of the shadow.

To obtain the best results with this method, an absolutely dark room is necessary. When maxillary sinusitis is suspected, a small electric lamp is placed in the patient's mouth, and the current is turned on until the face becomes luminous. One then compares both cheeks; if one sinus remains dark and the other light, we assume that the shadow is due to the exclusion of light by some affection of the dark sinus. Other phenomena noticed as a result of transillumination of the maxillary sinus are absence of a brilliant light in the pupil of the eye on the affected side, presence of shadow in the infraorbital region.

In transillumination of the frontal sinus, the electric lamp, properly shielded with a metal cover, is placed firmly against the floor of the frontal sinus at the inner angle of the eye. I have been using a double lamp for simultaneous examination of both frontal sinuses, thus permitting a com-

parison of the shadows cast. As to the diagnostic value of this method, it cannot be too strongly urged that absolute reliance is not to be placed upon the procedure, as it can be regarded only as one of the aids in establishing a diagnosis. Onodi, Hajek, and others have demonstrated that errors of diagnosis may frequently be committed because of variation in the thickness of the sinus walls, presence of septa, and differences in the consistency of the purulent secretion. Exploratory puncture offers the most reliable method of diagnosing maxillary sinusitis. The method of procedure is as follows: After thoroughly anesthetizing the inferior meatus with a 40 per cent. solution of cocaine, a trocar with a properly fitting cannula (Coakley's instrument is suitable for this purpose) is introduced into the sinus at a point directly under the attachment of the turbinate to the lateral wall of the nose and one-half inch behind the anterior end of the inferior turbinate. Moderate but firm pressure is all that is needed to enter the sinus. Pus may issue spontaneously from the cannula, but usually appears as a result of aspiration or irrigations of the cavity.

In recent years diagnosis of sinus disease by means of the *x*-ray has made rapid strides, so that this means is now regarded as invaluable not only in determining the presence of disease but by demonstrating anatomical anomalies present, determines the selection of the various types of operative procedures. For example, if by means of the *x*-rays inaccessible septa are demonstrated in the frontal sinus, or if the ethmoid cells are seen to extend over the orbital roof, an intranasal operation would not be selected. Furthermore, the height and depth of the frontal sinus can be shown, thus determining the type of operation, whether by the intranasal or external route. While of considerable value in the diagnosis of maxillary sinusitis, here it is of less importance, as other means previously referred to offer accurate and rapid means of diagnosis. As to the other sinuses, *i.e.* the anterior and posterior ethmoidal and sphenoidal sinuses, the *x*-ray findings by means of improved technique of today, are thoroughly reliable.

Treatment.—The kind of treatment directed toward the eradication of sinus disease, whether operative or non-operative, is influenced largely by the duration of the disease and the individual symptoms. For mild cases an expectant form of treatment is to be employed, while severer cases with evidence of the onset of serious complication involving the cerebrum or orbit call for urgent and energetic surgical measures.

Palliative local measures to be employed are of importance, inasmuch as they not only alleviate the acute symptoms, but by reducing the congestion permit of early restitution to normal, thus preventing the possible onset of complication.

To begin with, a 40 per cent. solution of cocaine in adrenalin, 1-1000, is thoroughly applied to the anterior end of the middle turbinate and the middle meatus, followed by irrigation of the nasal cavity with warm saline solution. This measure, repeated twice daily, contributes considerably to the relief of the patient's urgent symptoms. The hot saline irrigation not only washes away the excess cocaine solution but in addition serves the excellent purpose of relieving the intense congestion of the nasal and sinus mucosa. Inhalation of menthol, 10 per cent. solution in hot water, may be used. Passive hyperemia by means of an appropriate suction apparatus applied to the nostrils is a useful measure in the declining stage of the disease. I observed decided beneficial results at Killian's Clinic in Berlin from the use of superheated air applied to the nasal mucosa by means of appropriate apparatus. Electric light head baths, administered for 15 minutes daily, were effectively used for relief of the annoying neuralgic symptoms in frontal and maxillary sinus disease.

The use of vaccine therapy in the treatment of sinus disease has as yet met with indifferent results. Still, further experiments along these lines in certain types of subacute and chronic sinusitis are to be recommended.

In a majority of cases, as a result of free drainage which follows upon the application of the above measure, the acute condition soon subsides and restitution to normal is as complete as in the ordinary case of acute rhinitis. However, should the disease continue and become subacute or chronic, then resort to more energetic means of treatment becomes necessary. The object to be obtained in the treatment of chronic sinusitis is first of all to facilitate proper drainage and secondly to restore the lining mucosa to the normal. The first condition is met by the removal of any obstructions to drainage, *i. e.* removal of polypi (a frequently associated condition) resection of the anterior end of the middle turbinate, submucous resection of the septum, if a marked deviation to the diseased side is present. To restore the sinus mucosa to normal, frequent lavages with normal saline, boric acid, or permanganate solutions of the diseased sinuses are necessary to remove retained products of inflammation. If, following the removal of obstructive lesions in the nose, lavage produces the desired effect in relieving the patient of symptoms, this measure may be continued until all evidences of disease disappear. Should little or no improvement follow the above treatment employed over a reasonable period, the decision of having recourse to more or less radical operative procedures rests entirely with the patient. Many of these patients are content to go through life complaining of headaches of varying degrees, nasal discharge, etc. However, should repeated acute exacerbations follow, with or without the occurrence of cerebral or orbital complication, one is confronted with an absolute indication for surgical interference.

In recent years conservative surgical measures have replaced the more radical treatment formerly employed. Killian of Berlin on a number of occasions expressed the opinion to me that his well known operation for frontal sinusitis was used with far less frequency than in former years.

Conclusions.—1. Acute and chronic sinusitis is so frequent an accompanying condition of acute coryza, influenza, and other infectious diseases that a recognition of the early signs and symptoms should be at the command of the general practitioner.

2. Recourse to palliative therapeutic measures, when taken during the early stages of acute sinusitis, usually results in early restitution to normal.

3. In recent years radical operative measures in the treatment of the severer types of sinusitis have been replaced by conservative surgical procedures.

4. Absolute indications for radical operative treatment are definite, *i. e.* orbital or cerebral complications or frequent severe acute exacerbations of chronic sinusitis after persistent conservative treatment.

17 East Thirty-eighth Street.

Medicolegal Notes.

Authority of Employer's Agents and Servants to Contract for Medical Services.—Action was brougt by a physician against a railway company to recover for medical and surgical services rendered to an employee of the railway company, who was taken suddenly sick while loading a railroad track scale. The employee's foreman, Bernhart, endeavored to get the company's physician, and failing, called at the plaintiff's office and procured his assistance. He made an examination of Hanson, the sick man, who, on his advice, was taken to a hospital, where the plaintiff and three other doctors operated on him, discovering that he was suffering from a rupture of the walls of the stomach, which was caused by an abscess that had weakened the tissue so that the strain from lifting produced the rupture. The perforation was closed, the abdominal cavity cleaned out and sewed up, drainage put in and recovery of the patient followed. The plaintiff received a verdict and judgment in the circuit court for $150, from which verdict, however, the railway company at once appealed.

There was no claim of carelessness or negligence of the railway company. The labor in which Hanson was engaged was not especially hazardous; while the strain from lifting probably caused the rupture of the weakened wall of the stomach, it was not a strain that would have affected a normal man. There was no claim that the railway company employed the plaintiff to perform the service in question, or authorized anything in the matter, except in so far as it might be held liable for the acts of its foreman Bernhart, who was the foreman of a gang of two men. There was nothing to indicate any authority or apparent authority on his part to bind the railway company by any contract or agreement out of the line of his employment as a foreman in charge of a few laborers in the company's yards. There was conflict in the evidence as to whether he did or did not attempt to authorize or direct or acquiesce in the plaintiff's direction that Hanson should be removed to the hospital. But no officer or employee of the railway company gave any direction or assumed any responsibility as to the operation, and no employee of the company, other than Bernhart, had any knowledge of what was to be done, or what was done by the medical attendant at the hospital, until after the operation was performed.

The principal inquiry was whether there was any contract between the plaintiff and the company either expressed or implied. None was claimed except in so far as the company could be held bound by the acts of its employee Bernhart. The plaintiff insisted on the authority of Toledo, W. & W. R. Co. v. Rodrigues, 47 Ill. 188; Indianapolis & St. L. R. Co. v. Morris, 67 Ill. 295; Chicago Consol. Traction Co. v. Mathews, 117 Ill. App. 174, and Chicago & A. R. Co. v. Davis, 94 Ill. App. 54, that the request of Bernhart, the foreman in charge at the time of the occurrence, was sufficient to bind the company. But the court pointed out that in all these cases the liability of the defendant was based, not on the contract of some inferior servant, but on the ratification of the contract by some competent officer of the company.

In the Rodrigues case the general superintendent was presumed to have authority to ratify the contract of a station agent and the decision was based on the act of the general superintendent in ratifying the contract. In the Morris case the company was held liable for the services in question, not because of the contract of the conductor of the train, but because the officers of the company were notified of the services rendered and to be rendered at its expense, and it was held that it was its duty to notify the person performing the service if it did not intend to be held responsible, which it did not do.

In the Mathews case it was only held that the company was liable because when the plaintiff stated the case to the superintendent and asked as to a continuation of his services the superintendent made no direct reply, and therefore the trial court was justified in finding that the employment of the plaintiff by a conductor was ratified and confirmed by the company. In Cairo & St. L. R. Co. v. Mahoney, 82 Ill. 73, there was a recovery for services rendered at the request of a station agent, but the decision was based expressly on the ground that the employment by the station agent was ratified by the conduct of the general superintendent. And in St. Louis & K. C. R. Co. v. Olive, 40 Ill. App. 82, the right of recovery from the company on the contract of the conductor was expressly denied, because there was no evidence to show a ratification of such contract. In Chicago & A. R. Co. v. Davis, 94 Ill. App. 54, it was held that where an accident has happened to an employee and local surgeons of the company are not available, and the condition of the injured man requires prompt medical attention, the representative of the company in authority has the right to employ medical assistance, and thereby render the company liable for services. So far as the court could learn, the doctrine of the authority of an inferior officer in emergency cases, *i.e.* one in authority at the time and place of the accident, to bind his principal by contract for medical services rendered the injured in the absence of the company's physician rests on the dicta of the court in the Mathews case and the decision of the court in the Davis case. In the latter case the decision was based on the authority of the Rodrigues and Morris cases, and while the reasoning of those cases might tend to the support of such a rule, the court held that neither of them was express authority for it.

The rule is discussed and authorities reviewed in Salter v. Nebraska Tel. Co., 79 Neb. 373, 13 L. R. A. (N. S.) 545; and the conclusion is reached that under certain conditions such authority may be presumed without proof, and it is said: "This rule is one required by an emergency rather than one based on any general legal principle and that the authority of the officer with limited powers can extend no further than the emergency demands;" and that the "emergency services, unless expressly limited at the time of procuring them, ought to extend to a sufficient time for the party employed to communicate with the company, and, if it declines to be further responsible for notice to the proper poor authorities, if the injured party is entitled to public care." The authorities are to some extent reviewed in Bonnette v. St. Louis, I. M. & S. Ry. Co., 87 Ark. 197, and the authority of a conductor in charge of a train to employ a surgeon to attend a stranger injured in the running of the train was sustained on the ground that the emergency created the authority, the conductor being the highest agent of the company on the ground.

The railway company cited no authorities on this question of authority implied from the arising of an emergency, and its counsel said the question was too plain to require argument. It seemed to the court, from such examination of the reported cases as it had made, that the law is not settled either in the state of Illinois or by any uniform holding of the courts of other states. It seemed clear, however, that the foreman Bernhart had no authority to bind the railway company to pay for the services performed at the hospital. The surgeons presumably had time before operating on Hanson to communicate with officers of the railway company having apparent authority to act in the premises, and failing to do so they could not recover of the railway company for such services. But if it were a fact that Bernhart was the highest officer of the company on the ground, which it seemed to the court the plaintiff should have affirmatively proved, the court held that he had authority to employ the plaintiff to perform such temporary service, by way of first aid, as the occasion required, and therefore the plaintiff might on proper evidence recover in this action the value of the services rendered in treating Hanson in the company's yards and for such other and further service as the evidence might show was necessarily performed before he had time to communicate with authorized agents of the company; but he had no authority to employ other physicians and make the company liable either to them or himself for their services. The judgment was therefore reversed and the case remanded.—Aimone v. Chicago, M. & St. P. R. Co., 182 Ill. App. 592.

Expert Evidence—Medical Authorities.—A physician stated on cross-examination that in his opinion, partly from his own experience, the percentage of diabetes among people from thirty to fifty was greater than at any other period of life. He was asked, "What authority do you rely on in regard to that?" It was held that the cross-examining party should have asked him whether he relied on any medical authority and not have assumed that he did so, and the question was therefore very properly excluded.—Douglas vs. Berlin Dye Works & Laundry Co., California Supreme Court, 145 Pac. 535.

MEDICAL RECORD.

New York, June 19, 1915.

THE THERAPEUTIC VALUE OF HEXAMETHYLENAMINE.

It is unfortunate that so many of the newer remedies are at first accepted with unreasoning enthusiasm and later, when results seem not to be commensurate with the original expectations, are condemned with an enthusiasm just as active and unreasoning. It takes a long period of time and much experimentation to establish definitely the proper place for each remedy, and much of it is unnecessarily wasted. Salvarsan has passed through all these stages and its position seems now quite definitely assured. Hexamethylenamine has had to struggle more slowly through its probationary period. It was at first hailed as a universal antiseptic which was excreted in the bile, cerebrospinal fluid, nasal mucus, and the urine and capable of sterilizing all of them. The results obtained with its use did not fully justify these claims, and recently there have been several papers, especially in the literature in this country, which have endeavored to show that its value was limited to conditions in the urinary tract. Doubtless the pendulum is swinging too far to the negative side and eventually the true status of hexamethylenamine as a most useful drug, though not a panacea, will be established.

The most recent of these articles has just been published embodying the results obtained by Höst (*Zeitschr. f. klin. Med.* 1915, lxxxi, 272). He claims that Nicolaier's test for formaldehyde is more reliable and much more delicate than the Rimini test which has been used quite generally hitherto. He very definitely establishes the fact that the decomposition of hexamethylenamine into formaldehyde and ammonia depends upon three factors: the reaction, that is, the relation between the hydrogen and hydroxyl ion concentration; the absolute amount of the hydrogen ions; and the hexamethylenamine concentration. The temperature, which is an important factor, acts by influencing the degree of ionization. Thus he shows that if a solution of hexamethylenamine is raised to the boiling point decomposition takes place to a high degree, while if it is cooled again to zero the constituents recombine. All other things being equal the amount of the decomposition depends upon the time during which the action is allowed to proceed. So he agrees with other authors that an acid reaction is most favorable to the liberation of formaldehyde, but points out that even in faintly alkaline solutions the decomposition takes place, though very slowly. For instance, a neutral 0.2 per cent. solution will give a positive reaction for formaldehyde in fifteen minutes, while a solution of the same strength in N 10,000 sodium hydrate will give a positive reaction only at the end of twenty-four hours. A combination of the action of both heat and acidity results in a more complete decomposition than does either factor alone. They differ in that while a solution subjected to the influence of heat will yield only formaldehyde and ammonia, and these will wholly recombine on cooling, when the decomposition is effected by the action of acid there is produced also some methylenamine, and complete recombination does not take place on neutralization. Since the process is accompanied by the production of ammonia it is necessarily a self-limited one and will slow up as the acidity of the solution is diminished.

Höst states that hexamethylenamine is excreted by the kidney as such and that the decomposition therefore is proportionate to the hydrogen ion concentration and the time. It is partly broken down in the stomach and resynthesized in the intestines, and its time in the circulating blood is very short since it may appear in the urine within ten minutes of the time of its administration. He concludes that in diseases of the kidneys, renal pelvis, and ureters the therapeutic action is less marked since the urine is passed along so quickly, though there is possibly a better action when the urine is highly acid. In bladder conditions its value depends upon the reaction of the urine and on the frequency of micturition. When the urine is neutral or alkaline the effect will be more pronounced if the bladder is emptied at infrequent intervals.

EPITHELIAL PROLIFERATION.

As the result of numerous attempts to produce cancer experimentally by means of the injection of various substances, in which attempts Ribbert was the pioneer, Fischer discovered that scarlet-red, Sudan III, and indophenol have the property of stimulating the proliferation of epithelium. He attributed this power to the chemotactic influence exerted by the injected substance with respect to the attraxines of the epithelial elements. Alberto Marrassina (*Lo Sperimentale,* March 15, 1915) studied this subject anew, paying particular attention to the mechanism of the formation of atypical epithelial proliferation. He found that many of the substances capable of stimulating this proliferation in the ear of the rabbit are also oxidizing agents and concludes that it is not improbable that the stimulating power with reference to epithelial proliferation is at least in part associated with the oxidizing capacity.

The injection of the above substances into the lobule of the rabbit's ear is capable of accelerating the proliferation not only of the epithelium of the hair follicles, sebaceous glands, and epidermis, but also of the connective tissue and endothelium. In some cases there is an extraordinary predominance

in the proliferation of the epithelium, and in other cases in that of the connective tissue and endothelium. These differences depend upon certain conditions present in the animal experimented upon, as may be seen in the fact that in the rat there is a predominance in the proliferation of connective tissue and endothelium, whereas in the mouse there is a predominance in the proliferation of epithelium.

The addition of oleic acid to a saturated solution of Sudan III in olive oil does not appear sensibly to modify the result. If, however, one of the oxygen molecules of the oleic acid is replaced by a molecule of ozone, this tends to favor the process of proliferation. In many instances the proliferated epithelium has but slight resistance and rapidly undergoes corneous degeneration. It shows no tendency to infiltration and increases under the form of lobes or lobules that later assume the aspect of epithelial pearls. In other instances it forms cord-like masses that wind deeply and irregularly into the connective tissue, in the same manner in which epithelial tumors develop in connective tissue. The action of Sudan III and probably of other substances upon epithelium cannot be explained upon the basis of a chemotactic influence, but can be accounted for by assuming a stimulus of a blastic nature; for a similar action can be brought about by simply changing the normal equilibrium or relationships of the epithelium.

SALT IN THE DIETETICS OF PROTRACTED FEVERS.

THE study of the mineral component in the various diets for chronic ailments is a comparatively recent one. The use of common salt in this connection is of unusual interest. A diet rich in salt is believed to cause water retention and increase the weight, this being especially evident in renal insufficiency. To a layman it might seem that the greatly increased ingestion of water which accompanies a salty diet could in itself explain this gain in weight; but we know that the water retention which results from consumption of salt is a much more subtle phenomenon. Many subjects can ingest much salt daily without corresponding thirst and copious drinking. The great differences in weight between individuals and in the same individual at different times seem associated largely with ability or inability to retain water in the tissues, women especially showing remarkable fluctuations in weight within short periods which are inexplicable by ordinary reasons. No doubt such changes may in some cases be due to disordered mineral metabolism.

As is well known a milk diet, largely because of its poverty in salt, can be made to cause a rapid reduction in weight. Suppose, however, the patient has a chronic ailment and is bedfast, especially if the presence of fever forbids him to leave his bed. Does not the poverty of salt in his milk diet come in time to threaten him with deprivation symptoms?

Schütz, in the military supplement of the *Münch. med. Wochenschrift* for April 13, expresses his fear of such a contingency. Poverty of salt in the diet should in time affect unfavorably the production of gastric juice. It naturally occurred to him to add salt to the milk diet of patients with chronic elevation of temperature on general principles; but he hardly expected the brilliant results which he obtained. The patients at once began to feel much better and developed an appetite, doubtless as a result of increased acidity of the gastric juice.

LOCAL AMYLOIDOSIS OF THE HEART.

GENERAL amyloidosis as a result of bone suppuration, syphilis, etc., is sufficiently well known, but the localized types, which may have a different origin, are much less in evidence, being largely necropsy fluids without definite symptomatology. However, when so important an organ as the heart suffers from this condition, a phenomenon of clinical significance may be in evidence. At a recent session of the Halle (a. S.) Medical Society (*Münchener medizinische Wochenschrift*, April 13) Beneke discusses the few cases of this affection personally known to him (some five). The cases showed a sufficient resemblance to one another to constitute a type. Clinical and etiological data are scanty. One patient was a 74-year-old prostatic with pyelonephritis and cystitis, likewise chronic bronchitis. In regard to the heart it is asserted positively that the muscle, especially of the auricle, and also the endocardium, was permeated with spherules of amyloid substance. Of much interest is the fact that the process tended to involve the great veins while the arteries were spared. The amyloidosis did not penetrate within the muscular fibers and force them apart but involved only the sheath or external aspect. As studied in the heart, amyloidosis possesses a morbid similarity to the ordinary formation of connective tissue. A ferment catalyzator is doubtless responsible for the precipitation of amyloid substance from the lymph.

A METHOD OF VEIN DISTENTION FOR INTRAVENOUS INJECTIONS.

THE method of distending the superficial veins of the forearm preparatory to intravenous injection, advocated by Hoge (*Surgery, Gynecology, and Obstetrics*, December, 1914). is so simple and efficient that it deserves a word of appreciation. His method consists in the use of an inflatable rubber bag, such as the arm band from a blood-pressure apparatus, with a tube attached leading to a hand pump with a screw escape valve. When the operator is ready to proceed with the intravenous injection, the apparatus is adjusted to the upper arm by an assistant and the bag inflated until the desired degree of pressure and consequent distention of the veins has been obtaind. When the needle or cannula has been properly inserted into the vein the valve is opened and pressure rapidly relieved. The air release thus occurs without jarring the arm or disturbing the sterile field. The advantages claimed for the method are: That the degree of distention is easily controlled, and with a degree of accuracy that is not possible with an ordinary tourniquet, which is often tied too tightly, thus stopping both arterial and venous flow, or tied not tightly enough, causing insufficient distention; that there is no fumbling with knots, the entire procedure being controlled easily and well away from the site of operation; that there is no jarring of the arm in releasing the obstruction, hence the risk of displacing the needle is

thus prevented; and that there is minimal danger of injuring the intima of the obstructed vessels. The experience of those who have tried this method in a number of cases shows that the author's claims are entirely justified and that the method should be resorted to by those who have been so unfortunate as to have a perfectly placed needle jerked out of the vein by a sudden twitch of the arm during the removal of the tourniquet.

News of the Week.

Committee of American Physicians for the Aid of the Belgian Profession.—The treasurer, Dr. F. F. Simpson, 7048 Jenkins Arcade Bldg., Pittsburgh, Pa., reports the receipt of the following contributions for the week ending June 12, 1915:

New England Hospital Medical Society, Boston, Mass.	$30.00
Aux Plaines Branch of Chicago Med. Soc., Maywood, Ill.	41.00
Vigo County Medical Society, Terre Haute, Ind.	25.00
Dr. Jacob Schwinn, Wheeling, W. Va.	10.00
Dr. John Bryant, Boston, Mass.	10.00
Drs. Robert J. and John L. Sagerson, Johnstown, Pa.	10.00
Dr. Catherine H. Travis, New Britain, Conn.	2.00
Dr. George B. Lake, Manila, P. I.	2.00
Dr. M. J. Kenefick, Algona, Iowa	10.00
Dr. E. W. Link, Palestine, Texas (second contribution)	10.00
Receipts for the week ending June 12th	$153 00
Previously reported receipts	7,159.00
Total receipts	$7,312.00
Disbursements for the week ending June 12th:	
140 Standard boxes of food at $2.28.. $319.20	
Previously reported disbursements:	
1,625 Standard boxes of food at $2.20..$3,575.00	
1,274 Standard boxes of food at $2.30.. 2,930.20	
213 Standard boxes of food at $2.28.. 485.64	
Total disbursements	7,310.04
Balance	$1.96

Death Rate in New York City.—The Health Department reports for the first twenty-three weeks of 1915 a death rate of 14.44 as compared with 15.15 for the corresponding period of 1914. Several of the infectious diseases show a slight increase, which, however, is offset by reductions in the death toll of other diseases of this group. The greatest increase is seen under the heading of bronchopneumonia.

Virulent Smallpox at New Bedford, Mass.—The United States Public Health Service reports that there is at present an outbreak of virulent smallpox at New Bedford, Mass. Since May 15 there have been 10 cases, of which 3 have terminated fatally. Four of the cases have been of the hemorrhagic type.

Discounts on Surgical Instruments.—At the joint convention of the American Surgical Trade Association, the American Surgical Trade Credit Association, and the Wholesale Surgical Trade Association, recently held in New York, one of the statements made was that because of the great demand for surgical instruments of all kinds by the warring nations in Europe there is a shortage in this country. Discounts to physicians of 10 per cent. and even higher for cash payments have been cut to 2 per cent. Criticism was made of what was termed the questionable activities of certain classes of surgeons who sometimes get as high as 25 per cent. discount from dealers on purchases made by the patient. The latter as a rule gets no benefit from the reduction.

Tuberculosis Nurses.—The people of Los Angeles at the city election held June 1, passed by a vote of about two to one an initiative ordinance providing for the employment of municipal visiting tuberculosis nurses. The Health Commissioner of the City of Los Angeles is empowered to employ municipal visiting tuberculosis nurses in the proportion of one nurse per one hundred reported cases of tuberculosis. The above ordinance was drawn and fathered by Dr. George E. Malsbary, editor of the *Southern California Practitioner*.

A Diagnosis.—It is reported that Dr. G. of the Stamford Hospital called a New York surgeon one day last week for the purpose of making a differential diagnosis in a puzzling case with abdominal complications. The consultant who has the reputation of being something of a wag made a diagnosis of gallstones and stated that forty-six gallstones would be found in the gall-bladder. This proved to be the exact number, according to the testimony of members of the hospital staff who were present at the operation.

War Against Alcohol.—Dr. S. S. Goldwater, Commissioner of Health of New York City, has asked for the organization of a special committee of the advisory council of the Department of Health for the purpose of starting a campaign against the abuse of alcohol.

"Child Welfare Day."—The New York State Department of Health has designated Sunday, June 20, as "Child Welfare Day." Pastors of all denominations have been asked to cooperate and are receiving from the department data upon which to base sermons or short talks at one of their services on that Sunday. The educational campaign of the Division of Child Hygiene of the Department of Health last year brought about a decrease in the infant death rate from 137 to 112 per thousand births. This means that approximately 1400 deaths of infants were prevented.

Wood Alcohol in Toilet Preparations.—An investigation conducted by inspectors of the New York City Health Department last year disclosed the fact that more than one-third of the toilet preparations sold in this city contained wood alcohol. The use of wood alcohol in all preparations for human use, either externally or internally, is forbidden by the Sanitary Code, and manufacturers have been repeatedly warned through their trade papers concerning this provision of the law.

Mayo Offer is Accepted.—By a unanimous vote of the ten members of the Board of Regents present at the University of Minnesota on June 9, that body decided to adopt the six year trial period in which graduate medical work will be pursued at Rochester, Minn., under the offer of the Mayo Foundation, which makes available, in the event of a permanent arrangement, the income of a $2,000,000 endowment.

New Appointments to Willard Parker and Riverside Hospitals.—The following appointments have been made to the staff of the Willard Parker Hospital: Dr. Edward D. Fisher, consulting neurologist; Dr. James T. Gwathmey, special anesthetist and instructor in anesthesis to the Willard Parker and Riverside Hospitals; Dr. M. C. Pease, assistant attending physician; Dr. William Ropes May, assistant attending physician; Dr. Charles H. Smith, assistant attending physician. Dr. Lamont H. Fisher has been appointed assistant attending physician to the Riverside Hospital, and Dr. Harold Hays, assistant laryngologist to Riverside Hospital.

Campaign Against Venereal Diseases in Vermont.—A law enacted by Vermont on March 25, 1915, contains the following provisions: "A person who, knowing himself to be infected with gonorrhea or syphilis, marries, shall be fined not more than

$500 or imprisoned in the house of correction for not more than two years." "A person who, while infected with gonorrhea or syphilis, has sexual intercourse shall be fined not more than $500 or imprisoned in the house of correction for not more than one year."

Charitable Bequests.—By the will of the late Rosalie L. Hope, of Philadelphia, the sum of $2,000 is bequeathed to the Jewish Hospital for the endowment of a free bed in memory of her husband and herself.

By the will of the late Thomas A. McElwell of Philadelphia, the sum of $5,000 is bequeathed to St. Joseph's Hospital, to endow a free bed in memory of the testator's brother, Rear Admiral Jackson McElwell of the United States Navy, and the sum of $5,000 to St. Agnes Hospital, to endow a free bed in memory in the name of the testator. Also contingent bequests are made to St. Agnes, St. Mary's and St. Joseph's Hospitals.

By the will of the late Alice H. Richardson, the sum of $5,000 is bequeathed to the Episcopal Hospital, to endow a free bed in memory of William H. Richardson, and $500 to the West Philadelphia Hospital for Women for the endowment of C. D. Richardson Free Room.

Medical College Commencements.—At the annual commencement of the Women's Medical College of Pennsylvania, held at Philadelphia on June 2 the degree of Doctor of Medicine was conferred on 29 graduates, and an address was delivered by Dr. Richard C. Cabot of Boston entitled "The Mission of Medical Women in the Social Service Field."

The annual commencement of the Medico-Chirurgical College of Philadelphia was held on June 4, and the medical degree was conferred on 82 graduates.

At the annual commencement of Jefferson Medical College held at Philadelphia on June 5 the Doctorate was conferred on 146 graduates, and Dr. Victor Clarence Vaughan of Ann Arbor, Mich., president of the American Medical Association, delivered the valedictory address, entitled "A Doctor's Ideals." The degree of Doctor of Laws was conferred by the trustees of the college on Dr. Vaughan.

At the annual commencement of Temple University of Philadelphia on June 5 the medical degree was conferred on 24 graduates, and Dr. Charles E. de M. Sajous was made a Doctor of Science.

At the annual commencement of Cornell University Medical College held June 10, 1915, the medical degree was conferred on 20 graduates. An address was delivered to the latter by President Jacob Gould Schurman of the university.

Dr. Henry L. Elsner, Professor of Medicine in Syracuse University, has received the honorary degree of Doctor of Laws at the recent commencement exercises of this university.

Dr. Edward Livingston Hunt of New York has been appointed assistant professor of clinical neurology in the College of Physicians and Surgeons, Columbia University.

Dr. I. Arthur Stoloff of New York has been appointed Assistant Surgeon to the New York City Children's Hospitals and Schools, Randall's Island, under the service of Dr. William Seaman Bainbridge.

Dr. Francis H. Mead has resigned as health officer for the city of San Diego, Cal. The Board of Health on his resignation passed a resolution thanking him for his services during the past 8 years. He is succeeded by Dr. A. E. Banks, who has held the position of assistant health officer during the past 8 months.

Dr. Ella B. Everitt of Philadelphia has been elected president of Wilson College at Chambersburg, Pa.

Alumni Association, Medical Department, University of Buffalo.—At the annual reunion of this association held on June 3, due recognition was given to Dr. Peter W. Van Peyma, teacher as well as clinical professor of obstetrics for thirty years, who retires this year. The graduating class presented an enlarged likeness of Dr. Van Peyma to the university to be hung in the college library. The constitution and by-laws of the association were revised and steps were taken to establish an Alumni Endowment Fund which is to be used for the advancement of teaching and research work in the institution. The following officers were elected: *President*, Dr. Lesser Kauffman of Buffalo; *First Vice-President*, Dr. Charles D. Aaron of Detroit; *Second Vice-President*, Dr. Archer D. Babcock of Syracuse; *Third Vice-President*, Dr. James E. King of Buffalo; *Fourth Vice-President*, Dr. Jane W. Carroll of Paterson; *Fifth Vice-President*, Dr. Lee A. Whitney of Rochester; *Secretary*, Dr. Julius Richter of Buffalo; *Treasurer*, Dr. Frank E. Brundage of Buffalo.

Medical Society Elections.—The Dakota Medical Association at its annual meeting, held in Bismarck May 13, elected the following officers: *President*, Dr. H. V. Stickney, Dickinson; *First Vice-President*, Dr. V. J. Larose, Bismarck; *Second Vice-President*, Dr. George M. Williamson, Grand Forks; *Third Vice-President*, Dr. E. A. Pray, Valley City; *Secretary*, Dr. H. J. Rowe, Casselton; *Treasurer*, Dr. W. F. Sihler, Devils Lake; *Counselors*, A. S. Nicholson, Max; William Baldwin, Casselton; G. Golseth, Jamestown; Charles MacKachlan, New Rockford; *Delegate to A. M. A. Meeting*, C. S. Crane, Grand Forks; *Alternate*, James Aylen, Fargo; *Medical Defense Committee*, C. N. Callander, Fargo; *Recommended for Medical Examining Board*, H. O. Altnow, Mandan; B. L. Meiggs, Edgeley; H. O. Woutat, Grand Forks. The next meeting place of the association will be Devils Lake.

The Homeopathic Medical Society of the State of Kansas at its annual meeting held in Topeka, May 6, elected the following officers: *President*, Dr. W. J. Gates of Kansas City; *Vice-President*, Dr. S. W. Royer of Wichita; *Secretary*, Dr. C. E. Kinley of Kansas City; *Treasurer*, Dr. M. A. Swift, Topeka; *Delegates to the American Institute of Homeopathy*, Dr. S. A. Bass of Wichita, and Dr. W. J. Gates of Kansas City.

The Mississippi State Medical Association at its annual meeting held in Hattiesburg, May 13, elected the following officers: *President*, I. W. Cooper, Newton; *Vice-Presidents*, W. H. Scudder, Mayersville; J. W. Lucas, Moorehead; W. L. Orr, Fulton; *Counselors*, third district, C. M. Murray, Ripley; fourth, J. J. Underwood, Nettleton; ninth, J. C. McNair, Fayette; *Members of State Board of Health*, S. W. Glass, Lyon; T. F. Elkin, Tupelo; S. E. Eason, New Albany; J. H. Johnson, Brookhaven; T. H. Seay, Laurel; *Delegate to A. M. A.*, Dr. J. S. Ullman, Natchez. The next annual meeting will be in Greenville.

The Florida State Medical Association at its annual meeting held in DeLand, May 14, elected the following officers: *President*, Dr. H. McGinnis of Jacksonville; *First Vice-President*, Dr. W. R. Stevens of DeLand; *Second Vice-President*, Dr. Mary

Freeman of Perrine; *Third Vice-President*, Dr. Coffie of Fort Meade. Arcadia was chosen as the convention city for 1916.

The Windham County (Vt.) Medical Society at its annual meeting held in Bellows Falls, May 11, elected the following officers: *President*, Dr. W. F. Hazelton of Bellows Falls; *Vice-President*, Dr. F. L. Osgood of Saxtons River; *Secretary*, Dr. G. R. Anderson of Brattleboro.

The Jersey County (Ill.) Medical Society at its annual meeting held May 13, elected the following officers: *President*, Dr. A. A. Barnett; *Vice-President*, Dr. H. R. Gledhill; *Secretary and Treasurer*, Dr. A. R. Bohannon.

The Clinton County (Ill.) Medical Society at its annual meeting held in Carlisle, May 13, elected the following officers: *President*, Dr. J. W. Du Comb of Beckemeyer; *Secretary*, Dr. L. Niess of Trenton; *Treasurer*, Dr. Orville O'Neil of Shattuc; *Delegate State Medical Society*, J. W. Du Comb; *Alternate*, Dr. J. Q. Roane of Carlyle.

Obituary Notes.—Dr. Matthew Joseph McKenna of Brooklyn, N. Y., a graduate of the Long Island College Hospital, Brooklyn, in 1912, and until recently an interne at St. Catherine's Hospital, died at his home from nephritis, on June 4, aged 24 years.

Dr. Sumner Carruth Saville of Boston, Mass., a graduate of Harvard University, Medical School, Boston, in 1894, and a member of the American Medical Association and the Massachusetts Medical Society, died at his home in Cambridge on May 27, aged 48 years.

Dr. Reuben Robinson of San Antonio, Tex., a graduate of the University of Nebraska, College of Medicine, in 1896, formerly on the staff of the Creighton Medical College, Omaha, and a member of the State Medical Association of Texas and the Bexar County Medical Society, died at his home after a long illness, on May 20, aged 54 years.

Dr. William J. Gills of Farmville, Va., a graduate of the University College of Medicine, Richmond, Va., in 1901, and a member of the Medical Society of Virginia and the Mettauer County Medical Society, and secretary of the latter, died in a sanatorium in Richmond, from pellagra, after a long illness, on May 19, aged 37 years.

Dr. Frank Neall Robinson, formerly of Camden, N. J., died at Monrovia, Cal., on May 26, at the age of 41 years. He was graduated from the Medical Department of the University of Pennsylvania in the class of 1895. He was a Fellow of the American Medical Association.

Dr. Henry D. Moore of Philadelphia died on May 27 at the age of 50 years. He was graduated from Jefferson Medical College in the class of 1887. He was a member of the Philadelphia County Medical Society and of the Medical Society of the State of Pennsylvania and a Fellow of the American Medical Association.

Dr. Arthur Worrall Palmer of New York, a graduate of the New York Homeopathic Medical College and Hospital in 1883, a member of the American Institute of Homeopathy, the Homeopathic Medical Societies of the State and County of New York, the American Editors' Association, and the Academy of Pathological Science, surgeon to the New York Ophthalmic Hospital and laryngologist to the Metropolitan Hospital, and formerly editor of the *Journal of Ophthalmology, Otology, and Laryngology*, died at his home, on June 10, aged 54 years.

Dr. George W. Guthrie of Wilkes-Barre, Penn., a graduate of the University of Pennsylvania, Department of Medicine, Philadelphia, in 1873, a member of the American Medical Association, the Medical Society of the State of Pennsylvania, the Luzerne County Medical Society, the American Surgical Association, and the American Climatological Society, for many years president of the Wilkes-Barre City Hospital, and consulting surgeon to the Pittston Hospital and continuously since 1878 a member of the Wilkes-Barre School Board, died at his home, after a long illness, on June 1, aged 70 years.

Dr. Charles H. Colegrove of Willimantic, Conn., a graduate of the Detroit Homeopathic Medical College in 1873, and a member of the American Institute of Homeopathy, the Hahnemann Society of Michigan, and the Connecticut State Homeopathic Medical Society, died at his home, after a long illness, on May 29.

Dr. Gustavus Freedom Walker of Boston, Mass., a graduate of the Vermont Medical College, Rutland, in 1888, medical director of the Massachusetts Department of the Grand Army, and lieutenant surgeon of the Ancient and Honorable Artillery of Boston, died at his home on June 1, aged 72 years.

Dr. James Henry Joyce of Salem, Mass., a graduate of Tufts College Medical School, Boston, in 1903, formerly city physician of Salem, and a member of the Massachusetts Medical Society and the Essex District Medical Society, died at his home, after a long illness, on May 28, aged 35 years.

Dr. George Henry Hutchings of Woburn, Mass., a graduate of the Eclectic Medical College of the City of New York in 1884, died at his home, from heart disease, on May 30, aged 75 years.

Dr. James Orton Edie of Grand Rapids, Mich., a graduate of the Jefferson Medical College, Philadelphia, in 1874, a member of the Michigan State and Kent County Medical Societies, and the National Association of Railway Surgeons, formerly consulting physician to the Butterworth Hospital and the Union Benevolent Association Hospital, Grand Rapids, and on the staff of the Grand Rapids Medical College, died in Everett, Wash., on May 26, aged 78 years.

Dr. Robert Clement French of Natchez, Miss., a graduate of the Tulane University of Louisiana, School of Medicine, New Orleans, in 1906, and a member of the American Medical Association, the Mississippi State Medical Association, and the Adams County Medical Society, died in New Orleans, following an operation for appendicitis, on May 29, aged 37 years.

Dr. Joseph Walker Floyd of Tabor, N. C., a graduate of the Medical College of the State of South Carolina, Charleston, in 1900, and a member of the Medical Society of the State of North Carolina and the Columbus County Medical Society, died at his home, from apoplexy, on June 4, aged 41 years.

Dr. Daniel R. McCormick of Lancaster, Penn., a graduate of the Jefferson Medical College, Philadelphia, in 1882, and a member of the American Medical Association, the Medical Society of the State of Pennsylvania, and the Lancaster County Medical Society, died at his home on May 31, aged 50 years.

Dr. B. Frank Zerbe died of meningitis at Schaefferstown, Pa., on May 31 at the age of 61 years. He was graduated from Jefferson Medical College in the class of 1878.

Dr. JAMES MACARTHUR of London, Ont., a graduate of the Medical Faculty of Queen's University, Kingston, Ont., in 1878, and one of the founders of the London Medical Association, died at his home suddenly on May 23, aged 60 years.

Dr. J. M. GUESS of Centerville, Ga., a graduate of the University of Georgia, College of Medicine, Augusta, in 1878, died on May 26, aged 61 years.

Dr. ISAAC R. LANDIS died at Philadelphia on May 29 at the age of 74 years. He was graduated from Jefferson Medical College in the class of 1865.

Dr. HARRY H. SHERK of Camden, N. J., died at Philadelphia, on June 1 at the age of 56 years. He was graduated from Jefferson Medical College in the class of 1886.

Dr. JOHN S. MACK of Schaefferstown, Pa., died at Buffalo, N. Y., on May 30 at the age of 45 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1892.

Obituary.

COLONEL CHARLES E. WOODRUFF,

NEW ROCHELLE, N. Y.

CHARLES EDWARD WOODRUFF, Lieutenant-Colonel, U. S. Army, retired, died at his home in New Rochelle, N. Y., June 13, after a long illness. He was born in Philadelphia fifty-five years ago, received his early training at Annapolis, and in 1886 entered the United States Navy as a surgeon. A year later he resigned this commission to accept a similar one in the army. He became chief surgeon of brigade on Gen. Merritt's staff in the Philippines. Later he was commissioned by the Government to make a tour of inspection of foreign army posts. During his long service in the tropics Colonel Woodruff made a special study of ethnic conditions, the results of which study are recorded in his well-known works on "The Effects of Tropical Light on White Men" and "The Expansion of the Races." The last product of his pen, entitled "Medical Ethnology," has only recently been issued from the press. Colonel Woodruff wrote the article on this subject in the Reference Handbook of the Medical Sciences. He was a frequent contributor to the MEDICAL RECORD and other journals, and recently became associate editor of *American Medicine*. The death of Dr. Woodruff will be sorely felt by all who have recognized in him the scholar, the patriot, and the gentleman.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

THE WAR—ALLEGED SCARCITY OF DOCTORS AT HOME—PHARMACISTS' OFFER—R. S. M. TYROSINE—ANEURYSM—ISOLATING TYPHOID ORGANISMS—THYROIDISM—TUBAL PREGNANCY—OBITUARY.

LONDON, May 28, 1915.

THE war is still the uppermost subject at every casual meeting. Even medical men when they meet let it overwhelm all other topics. The National Health Insurance Medical Research Committee is devoting its energies to points connected with the war. They are compiling statistics as to the sick and wounded and assisting the military hospitals in their pathological work. In some instances they have equipped laboratories in these hospitals for special researches, mostly in connection with the R. A. M. C.

One effect of the state of war is more talked about than otherwise perceived; we are told that the needs of the army have already occasioned a scarcity of medical practitioners at home. No doubt, here and there the absence of busy men who have left civil practice for military service makes some difference to those remaining, but I feel sure they will be able to cope with the extra work. Indeed we have long been accustomed to lament the overcrowding of the profession and yet with a prospect of some diminution there is an opposite outcry. There is a movement to allow medical students who have enlisted towards the end of their curriculum to return and fulfill it, as they would serve their country better as surgeons than in the ranks. This is perhaps reasonable provided the clinical part is not diminished, the lectures being of less importance than the bedside work in the wards.

Taking advantage of the outcry certain pharmacists are putting forward a claim to be admitted to the medical profession on special terms, such as being excused from examination in the matriculation and on subjects they have already been tested in, *e. g.* chemistry and materia medica. This may not be very objectionable, but obviously hospital work must not be diminished in the least and the entire examination can be on a clinical and practical basis.

At the Royal Society of Medicine Dr. H. Charlton Bastian, in a paper on "Tyrosine as an Aid in the Demonstration of the Present-Day *de novo* Origin of Living Organisms," has put forward some reply to the incredulity with which his deductions from experiments as to spontaneous generation or "archebiosis" as he terms it, have been received. The attempts to explain them away he ranges under three suppositions: (1) That the bodies found were mere simulacra or pseudoorganisms. (2) That they were dead, having preexisted in the material experimented with and been killed in the sterilization. (3) That they had come from an impure pipette, or dropped from the air on to the slide before a cover glass had been applied. In answer to 1 and 2 he held that tyrosine had proved valuable since a small quantity of a very dilute solution caused any living organism present to grow and multiply freely. He described the effects observed on tubes opened at different periods and compared with one another and reclosed and opened again at another period. Growth was always found, proving they were neither dead nor simulacra. When tyrosine was added to new tubes they all remained sterile.

Dr. Kingston Fox exhibited an aneurysm of the left ventricle which projected from cardiac apex and looked about as big as a cricket ball. The aortic valve showed sclerotic change and the coronary artery some thickening of its walls.

The arc light method of isolating typhoid organisms devised by Professor Dreyer was demonstrated by him jointly with Dr. W. Ainley Walker. The former said the maximum effect was shown by the ultra-violet rays, but the ultra-red were also very effective. It was possible to isolate microorganisms by this means when ordinary bacteriological methods were of no avail. Professor Dreyer also demonstrated the agglutination method named after him. Dr. Ainley Walker considered this method reliable and an easy way of distinguishing an active case of typhoid from one in which immunity had been reached. It allowed

comparison of the agglutinating power of a patient's sera on succeeding days.

In another section (psychiatry) Dr. M. Kojima gave the results of examination of the thyroid gland in 110 cases of mental disorder. In this "consecutive series" all the ductless glands were carefully removed from the body and weighed. The minimum average weight in the non-insane was 22 to 25 grams. In the insane much less, 16.5 in males and 16.87 in females. But great variation was noted in the insane, especially in females. He considered all exhibited hypothyroidism. Dr. Mott (president) gave a microscopic demonstration of changes in the nervous system in hypothyroidism. Dr. Armstrong-Jones showed cases to illustrate a condition due to loss of function of the thyroid gland. Sir V. Horsley had shown the effect of removal. In children absence of thyroid produced sporadic cretinism, in adults myxedema.

In the obstetrical and gynecological section Dr. C. E. Purslow demonstrated a case of tubal pregnancy, showing the fetus undergoing dissolution removed by abdominal section from a married multipara Oct. 31. Menstruation had been regular until twelve weeks before admission to hospital., then amenorrhea until a fortnight before admission, since when there had been continuous slight loss. Two attacks of pain and faintness had occurred. On examination tubal pregnancy was diagnosed, though some signs were unusual. The swelling was above the pelvic brim and could not be reached by the finger per rectum or per vaginam. The specimen showed unruptured distended tube. Cross sections had been made showing diameter to be 2¼ in. Tube filled with firm blood-clot with cavity in center containing turbid fluid, in which was the macerated head of a fetus of about 10 weeks growth —no other part of fetus found.

Dr. Blair Bell read a paper to show that infundibulin introduced by him in 1909 had established its power of promoting rhythmical contractions during and after parturition, for which purpose he first introduced it.

The annual meeting of the Medical Society of London was held on the 12th inst. when there was an exhibition of early books on naval and military surgery besides other works in the society's library and objects of interest from various sources. The president, Mr. D'Arcy Power, gave a demonstration with the epidiascope and exhibited a silver penny struck in the reign of Henry III.

Surgeon-General Arthur James Payne died on May 21 in his eighty-ninth year. His career was in the Indian Medical Service in which he attained the rank of surgeon-general in 1885.

JAVA AND ITS MEDICAL SCHOOL.

(From Our Special Correspondent.)

A TRIP TO JAVA—ITS HOTEL ACCOMMODATIONS—THE JAVA MEDICAL SCHOOL.

BUITENZORG, JAVA, April 2, 1915.

A TRIP to Java is a very interesting journey not only for the tourist but for the medical man as well. Batavia, the largest city of Java, is 528 miles from Singapore. Steamers are frequent and the journey over the equator is pleasant. The steamers Melchor Treub and the Rumphius are the pride of the Dutch people. They are beautifully appointed and fast. One or the other of these vessels leaves Singapore every Friday evening and arrives at Tandjong Priok, which is the seaport for Batavia, early Sunday morning. There is a train about once an hour and Batavia is reached in 20 minutes.

The hotels are built entirely different from those in other parts of the world. A first class hotel consists of many two story buildings, arranged around a square that is as large as the average city block. These buildings have two sets of quarters on the first floor and two on the second floor. The quarters are entirely separate; each has its own entrance. There are separate driveways from the street, and the rooms can be entered or left with the same privacy as though the house were located in a park. When a guest registers for a room he is assigned to one of these sets of quarters. Each consists of a vestibule, a huge front veranda, a bedroom about 20 x 20 feet, a rear veranda, a toilet room, and a bath room. The office and dinings rooms are located near the center of the square. At other places in the grounds there are buildings which are used for reading rooms, library, billiard rooms, social hall, etc. The grounds contain many trees, flowers, shrubs and other plants, and artistically arranged walks lead in all directions. A servant is assigned to each guest, who looks after the quarters, waits upon him in the dining room and attends to his personal wants.

For the medical man one of the principal objects of interest is the medical school. As a rule anything undertaken by the Dutch in Java is done well, and the medical school is no exception. It maintains a standard that would serve as an excellent example to many schools in the United States. The only medical school in the Netherlands India is located in Batavia and is called the Schoot Tot Opleiding van Inl. Artsen. Another school is now being started in Sourabaya but it will be very small.

The Batavia institution was founded about 1865. It now has 116 students, and graduates from 10 to 15 per year. As only a few men come from abroad to practise, and as the population of Netherlands India is about 52,000,000, it will be noted how hopelessly inadequate this small number is to meet the needs of the inhabitants.

The course is nine years, but only six of these are spent in the medical department proper. It differs from most medical schools in that it has an academic department where a three-year preparatory course is given before the study of medicine is begun. The academic department was found necessary because there are no universities or other higher schools in Java where an education suitable to enter a medical school can be obtained.

Entrance to the preparatory course requires credits comparable to the first year of the average high school of the United States. An excellent general education is given in this school, and on account of its being conducted in connection with the medical school, it is possible to lay special stress on those parts of the course which are believed to be desirable to meet the needs of the medical school. To graduate from this course three years' attendance is necessary as well as to pass the examinations, which are equivalent to those of the first college year of an American university.

The medical course is six years, and compares very favorably with the standard established for class A colleges by the American Association of Medical colleges, and in some respects the requirements are higher. The school year extends over ten months of the year and an average of 26 hours instruction per week is given. A study of the curriculum and an inspection of the work of the stu-

dents, and seeing the teachers and pupils at work gave the impression that the course is thorough. There are eight whole time professors. The school is located near the military hospital, which has over 500 beds which are accessible to the students. During the last two years the students are required to live in the hospital and render regular duty as internes in so far as their school studies will permit.

The instruction is given entirely in Dutch. Much time is required to prepare Javanese students to receive medical instruction in that language. Every effort is made to make the course practical and much bedside teaching is done. Over 40 cadavers are dissected each year, which is an average of approximately 2 per student during the time he is studying anatomy.

The students are practically all Javanese males, although girls are admitted, and one is taking the course now. They enter the preparatory course from 12 to 16 years of age. By the time the preparatory course is finished most of the undesirable students have been weeded out. The Javanese are eager to learn, and make excellent students. The teachers report that they compare very favorably with students in European schools in their ability to assimilate knowledge. Discipline is excellent and very little difficulty is experienced in having them obey the rules. They pay no tuition fees. They are furnished with free board, lodging, books, in short, everything required to study medicine, and in addition they receive an allowance of $6 to $10 per month.

The government meets the entire expense of the school. There is now in course of construction at Salemba, a new medical school building which will accommodate 400 students. Even the present building is well adapted for the purpose. The laboratory space and equipment is excellent.

In addition to the clinical instruction at the military hospital there is actually conducted in the school by the instructors an outpatient dispensary. The students are required to take an active part in the work of the clinic under the immediate supervision of their teachers.

There is also conducted in connection with the school a students' club in which there are a general reading room, billiard tables, etc. The professors state that the contentment and discipline have improved greatly since the club was started.

Progress of Medical Science.

Boston Medical and Surgical Journal.

June 3, 1915.

4. Urethral Caruncle. E. L. Young, Jr.
5. Cutaneous Tuberculosis. Report of a Case of Folliclis and Erythema Induratum. J. H. Bufford and C. G. Lane.

2. Surgical Treatment of Flexed Scapulæ.—H. W. Marshall states that Goldthwait has devised the operation of removing the tips of the superior angles, and has proved that painful symptoms in backs may be stopped if offending exostoses or abnormally flexed upper parts which scrape over the ribs are trimmed sufficiently to prevent further friction and irritation. This operation has been performed by orthopedic surgeons at the Massachusetts General Hospital upon eleven patients during the four years ending January 1, 1912. In the routine examination of many back cases in any large orthopedic clinic there are discovered numerous examples of slight tenderness without crepitus among scapulæ of debilitated persons. Pain is referred to the scapulæ, to the region between them, and around to the sternum in acute cases. It radiates up behind the ears at times and also down the arms, and there may be crampy sensations in the trapezius muscle as the latter tries involuntarily to hold the shoulder in a comfortable position. Pain is noticed upon motion, especially when the arms are moved in directions that demand greatest rotation of the blades. Shrugging the shoulders, with arms hanging passively at the sides, will produce painful symptoms due to the scraping of abnormal scapulæ. The pains of subdeltoid bursitis, inflammation of the shoulder joint itself, injuries of the acromioclavicular joint, neuritis, and myalgias have to be differentiated; but in combination with local tenderness and scapula crepitus there is usually little difficulty in determining scapula lesions. All the patients exhibit greater or less degrees of round shoulders. The condition originates in an habitual bad posture of the shoulders during early life when the bones are readily moulded into various degrees of flexion. As the bones strengthen and harden in adult life they retain their peculiarities, and can be changed only by operation.

4. Urethral Caruncle.—E. L. Young, Jr., notes that the pathological examination of this type of growth shows a surprisingly large percentage of cases in which the question of malignancy is raised. As there is clinical evidence to show that certain cases turn out to be carcinomatous later, it would seem wise to examine all specimens when possible and to watch carefully the suspicious ones. About 50 per cent. of caruncles have no accompanying symptoms and where urinary symptoms are present a large proportion are probably not due to the growth. Thirty-three per cent. of all cases of the author's series have recurred regardless of the type of operation and where a stricture was present it has always recurred.

10. "Lest We Forget." J. W. Kennedy.

3. Prognosis in Mental Disease.—M. J. Karpas points out that psychoses may assume any of the following terminations: (1) Complete recovery with or without recurrence. (2) Recovery with defect symptoms. (3) The course of the disease may be progressive and may terminate in a state of intellectual deterioration varying in intensity. (4) Progression of mental symptoms (as in the paranoiac group) but without true dementia. (5) Fatal termination by reason of the nature of the mental infirmity. All forms of psychoses, be they organic, functional, or toxic, develop upon an inferior mental soil. In dealing with the prognosis of mental diseases, we should take into consideration not only the acute disturbance but also the constitutional make-up of the individual. After one has succeeded in carrying our patient through the critical period of the disease, one should then adjust the mental organism to an environment that would meet its needs without deleterious effects.

4. **Secondary Carcinoma of Bone.**—A. A. Matthews calls attention to the fact that when bone metastases occur early, while the primary area is still small and insignificant, the patient seeks the physican on account of the secondary suffering. Examination by the physician then reveals that prostatic, breast, gastric carcinoma, etc., is the primary focus of the bone tumor or there is a history of operation for cancer at some previous time. The symptoms of bone metastasis depend on the location and rapidity of growth of the cancer. Bone pain occurs in the later stage and is often unbearable. The affected skeletal areas show various deformities after localization. In vertebral metastases growths, angular or curved, with or without spinal cord symptoms, occur. Metastases in the bones of the skull cause symptoms aside from the local bone pain. In metastases of the extremities, pain, loss of function, and deformity occur. As to the operability of bone carcinoma, this is indicated only in solitary tumor, and even in these cases it is doubtful whether surgical procedures effectively remove all cancerous strata.

7. **Papilloma of the Bladder.**—C. W. Shropshire and C. Watterston conclude that all papillomata should be treated primarily with the high frequency current in view of the high percentage of recurrences following open operations—50 per cent.—and the high mortality —10 per cent. They should be watched for recurrence over a period of one year. A specimen should be examined in every case by a pathologist and, if found malignant, the tumor should be treated accordingly, for up to the present time fulguration has not proved effective in cases of malignancy.

3. **Alcoholic Injection of Nerves.**—W. B. Cadwalader states that intraneural injections of alcohol have been successful in the relief of the severer forms of neuralgia, the alcohol destroying the sensory fibers, at least for a time. The motor fibers, however, must also suffer, as alcohol has no selective action on the differently functionating fibers of the nerve. This is of the greatest importance in mixed nerves, as paralysis, more or less permanent, occurs. If a method of using such injections could be perfected that would diminish the degree of motor paralysis without lessening the sensory effects, it would be a boon. The author gives an account of experiments on dogs, in which the sciatic nerve was injected with the required solutions. After a certain time, the animals were killed, and the nerves removed for microscopic study and comparison. With 80 per cent. alcohol paralysis was immediate and complete; but with 50 per cent., it was not so severe; while 25 per cent. alcohol had little or no effect and examination showed no destructive changes. Salt solution caused no degeneration or paralysis and the mere procedure of inserting the needle caused no disturbance or hemorrhage or subsequent scar tissue. The deductions from these points were that strong alcoholic solutions completely destroyed the nerve fibers but, nevertheless, they were still capable of regeneration and recovery of function. There is abundant clinical evidence to prove that regeneration and functional restoration do occur, provided there are no complications. The experiments, however, do not warrant conclusions as to the length of time required. It is not impossible that in some cases the effects of very slight injury, like puncture of a needle, might be severe. In cases of facial spasm, for example, it would seem that repeated and gradually increased injections of the weaker alcoholic solution might relieve spasm at the cost of a greatly diminished paralysis.

5. **Indications for Surgery in Goiter.**—V. P. Blair concludes that toxic simple goiters and exophthalmic goiters that are still active are entitled to some sort of operation that tends to lessen the bulk or activity of the gland. Adolescent goiters, with rare exceptions, require no operation. Simple goiters are to be dealt with according to the indications of the individual case. Pregnancy greatly increases the risk of radical goiter surgery.

6. **The Abderhalden Reaction.**—F. H. Falls reviews the present status of this reaction as follows: The Abderhalden test is not a specific and infallible test for the diagnosis of pregnancy, carcinoma, or any other condition. A negative reaction in a given case is of great value as speaking against the possibility of pregnancy. A positive reaction must be interpreted as only speaking for the diagnosis of pregnancy, and that only in the absence of a large number of pathological conditions, to some of which I have already called attention. The ferments are increased in the blood during pregnancy. As yet, however, no way has been devised of differentiating between these ferments and the ferments mobilized in many pathological conditions. The test should be performed in all cases in which the diagnosis of pregnancy is in doubt, with a full knowledge of its limitations and possible error. It should be regarded as corroborative evidence together with other clinical phenomena.

7. **The Feeding of Bile in Biliary Obstruction.**—J. C. A. Gerster reports the case of a man who, after an operation for gallstones, suffered from a biliary fistula through which all the bile escaped, leaving him in a pitiable condition. The tentative closure of the fistula caused cramps and failed to divert the flow of bile into the duodenum; evidently there was an obstruction of the common duct. The patient's general condition forbade operation and, following the method described by Schmilinsky in a similar case, all the bile was collected through a catheter snugly fitting the fistula and passed into the stomach by the stomach tube twice a day (8 ounces each time). The procedure was followed by remarkable improvement. Fifteen days later a stone impacted in the papilla of Vater was taken out under local anesthesia. After the second day convalescence was uneventful and the man was discharged cured three weeks later.

3. The Ciliary Body.—H. P. Dunn lays stress upon hypothyroidism as a causative factor in cases of iridocyclitis and upon the usefulness, clinically, of its recognition. That the ciliary body, so sensitive to toxemic influence, should readily respond to thyroid treatment is a natural sequence to the vascularity of its structure. Thus there is placed in the hands of the ophthalmic surgeon a means of relief, yielding results which can be obtained in no other way. The dose of the extract employed by the author for children beyond five years of age and for adults is three grains twice daily, and from this dosage he has never seen any ill effects.

5. Hypertrichosis in the Insane.—C. T. Ewart states that one cannot pass through the wards of an asylum without being impressed by the number of female patients showing an excessive overgrowth of hair on the face—a number much larger than can be seen in any haphazard collection of women selected from the every-day world. The overgrowth is not a mere pencilling of down on the upper lip and chin, but consists of hirsute appendages capable of arousing in some men a feeling of envy. It would also be observed that these cases are represented by a lusty and strong type of physique, thus conveying the impression that the overgrowth is correlated with animal vigor. The author suggests that there is evidence which goes to show that the secretions of the suprarenal glands may be important factors. Some forms of cortical overgrowth of the suprarenals cause an early adolescence and sexual precocity. The young male acquires hair on the face and pubes years before the proper time, and his body at nine years becomes that of a diminutive but strongly built man. The female, curiously enough, under like conditions, loses the characteristics of her sex, hair growing on the face, and her body assuming a masculine contour.

2. Traumatism and Tuberculosis.—Sir Thomas Oliver describes the relationship of traumatism and tuberculosis as follows: Tuberculosis develops in a person who, until the accident, was believed to be quite healthy; a latent tuberculosis is roused into activity by the accident; a tuberculous lesion becomes localized at the site of injury, the microorganisms having been carried thither from a focus elsewhere in the body, or injury has simply aggravated a localized lesion which was previously present. Although there is no tuberculosis without the tubercle bacillus, the part played by the condition of the body, as exemplified in general and local resistance, cannot be ignored, and it is here that injury, by reducing resistance, comes in as a possible factor in the development of the disease.

6. The Cause of Appendicitis.—B. Hughes advances the theory that all cases of appendicitis are in the first place due to a mechanical cause, and this consists in a rotation of the organ about its mesoappendix. I consider the acute inflammatory process, whether it go on to abscess formation or not, is purely secondary to this rotation. This is assumed for the following reasons: The valve of Gerlach is by no means a reliable valve. In almost all quiescent appendices, which have never given rise to any symptoms and which have been removed during pelvic operations, the author has always been able to culture intestinal organisms from their cavities—that is, the normal contents of the appendix are not sterile. What happens when the appendix rotates? Anatomically the appendix is quite free to rotate on its mesentery, and as to what actually takes place will depend upon the degree of rotation. If the rotation be complete, then the condition is similar to that of an ovarian cyst completely twisted about its pedicle. The venous return is stopped, but the arterial supply is not wholly cut off. There is initially a state of acute congestion. Infection supervenes on this damaged organ, and gangrene with abscess is the usual termination. This type of case is familiar in that its onset is sudden, the pain is acute, the patient vomits, which vomiting the author regards as purely reflex; in fact, the initial symptoms are similar to those of a twisted ovarian cyst in the female. In less acute cases the rotation is not complete,and the venous return is not wholly cut off. These patients, if put to bed and kept quiet, invariably get over their first attack. The symptoms at the onset are not so acute; there may be vomiting, certainly some pain; there is tenderness over McBurney's point, but all this usually subsides. These patients, if operated upon in the acute stage, have always, in the author's experience, shown some degree of rotation of the appendix. The organ is stiff and congested, and there are subserous hemorrhages. Similar cases operated upon in the quiescent periods have shown the familiar kink in the organ, and if this be carefully examined it will be found to be produced by a partial rotation of the organ about its mesentery. The third type of case is that in which there is a long mesoappendix and the organ from mechanical conditions is rotating on its mesentery and recovering itself. The chief factors which bring this rotation about are a movable loaded cecum and a loss of tone in the abdominal muscles. The more important is the second of these two factors, for on it in some measure depends the first. A loaded movable cecum is free to move in three ways: it can descend, it can move laterally, or it can expand forward. These three conditions are just those required for a rotation of the appendix on its mesoappendix, and the only condition that can bring these about is constipation. Loss of tone in the abdominal muscles is one of the commonest causes of constipation and later of some amount of enteroptosis.

Typhoid Abscesses.—Willimczik states that the formation of cutaneous abscesses is one of the rarest complications of typhoid fever, meaning, of course, abscesses due directly to Eberth's bacillus. During the present war the author has had the opportunity of studying many cases of complicated typhoid on the eastern war front. He has seen hemorrhagic forms, arthritides, cardiac complications of many kinds, emboli and pulmonary abscesses. Quite a number of patients presented the cutaneous abscesses. Of these the author made a special study with reference to bacteriology. The genesis of the abscesses might be due partially to

want of care of the skin, uncleanliness, and general want of sanitary conditions. Literature teaches that an abundance of abscesses due to ordinary pyogenics have been seen to affect typhoid patients, and are akin in cause to furuncles and in part to severe decubitus lesions. On the other hand, Curschmann never saw more than one case of abscess due to typhoid bacilli, and the total number known to exist must be exceedingly small. The question arises as to the possibility of such abscesses developing at the site of hypodermic injections. The author has now been able to place on record three cases of these abscesses thoroughly studied, and has accumulated a number of data as follows: Abscesses in typhoid fever which are due to uncleanliness, etc., contain only pyogenics; abscesses caused by metastases through the blood stream are specific and caused by the typhoid bacillus. These differ notably from the common type, which shows evidences of irritation and tend to occur in the more cachectic subjects. The metastatic abscesses show no signs of irritation, are cold and resemble tuberculous abscesses. We may assume as necessary for their origin a local factor—a locus minoris resistentiæ—or an embolus. The former factor was well in evidence in all three cases. In two of them it was associated with the site of hypodermics of caffein and camphor, both mechanical and chemical irritation thus being in evidence. Other less pronounced local factors might also be accused. In none of the cases, on the other hand, was there any evidence of embolism, or any reasons for believing in the existence of a general blood contamination like typhoid septicopyemia.

Essential Thrombopenia.—Under this title Frank describes constitutional purpura, otherwise pseudohemophilia, originally morbus maculosus Werlhoffii. Formerly this was erroneously regarded as one form of hemorrhagic diathesis, but while profuse hemorrhages occur in this condition no hemorrhagic diathesis is present. Hemophilia is an exquisitely familial disease, while purpura hemorrhagica is not handed down. It will suffice, therefore, if we call the latter pseudohemophilia. The so-called purpura simplex and purpura rheumatica, once regarded as a degree of purpura hemorrhagica, is probably only an anaphylactic phenomenon. The true morbus maculosus is in reality a very rare affection at the present time. The author has seen four cases, which were well followed up and cites as many more cases recently reported by others. The article will be continued.

April 27, 1915.

Principles in the Treatment of Individual Local Wound Inflammations.—Von Herff first discusses numerous disinfectants, including bactercides, and substances with penetrative powers which diminish the virulence of germs. He next introduces a class of substances which "injure the culture bed." The latter have been worked out *in vitro*, and it is now known that the action of sublimate is due much more to the latter property than to any germicidal power. We need, therefore, some admixture of substances which possess a maximum of penetration with a minimum of toxicity along with some destructive action on the nutrient substances in the injured tissues. Phenol exerts a notable penetrative action, and hence while not a germicide of the first rank can greatly weaken the virulence of the bacteria. On the other hand, phenol is toxic. To begin with the surface, the author recommends mechanical disinfection of all kinds, stopping short of injuring the protective granulation wall. Forced irrigation under high pressure seems at present ideal. The water flushes out all recesses. A suction element can readily be combined with flushing. While sterile water may answer for irrigation, the author thinks it well to add some antiseptic powder. Unfortunately, not many of these are soluble either in water alone or with addition of glycerin, acetone or alcohol. The author discusses many solutions, such as iodine in dilute alcohol (1 part of the former to 1,000 parts of 50 or 60 per cent. alcohol). Warm disinfectants possess greater bactericidal powers than cool ones. If hydrogen peroxide is warmed to body temperature it furnishes one of the most practicable disinfectants for irrigation. Thus a 0.6 per cent. warm solution is equal in power to a 2 per cent. cold solution. The choice of disinfectant, however, is largely determined by the cause of the individual lesions. Should this be the staphylo- or streptococcus, nothing does so well as an initial application of 4 or 5 per cent. of carbolic acid, to be removed at once by irrigation. Hydrogen peroxide, by reason of its property of foaming, makes a superior irrigation fluid, and the nascent oxygen developed tends to destroy the tissue culture media. It is nontoxic, and as already stated, has a much stronger antiseptic action when warmed. The author adds that its action is also much enhanced by acidulating with a little acetic acid. For gas forming bacilli irrigations with chlorine water, iodine tincture, and especially oxidizing solutions such as H_2O_2 and permanganate of potassium are indicated.

Treatment of General Septic Conditions.—Hüssy, who is associated with von Herff, gives a supplementary article with the preceding title. The dicta of both men repose largely on their experience in the treatment of puerperal fever. Naturally the first step, that of diminishing the blood contamination, has already been covered under local treatment. This is indeed our chief dependence. Of internal remedies we know of but two which possess any power over the course of general sepsis. These are silver derivatives and formaldehyde derivatives. But little is said of the latter, beyond that urotropin has shown power over typhus. In regard to silver Hüssy speaks with encouragement of a combination of methylene blue and that metal which has recently been placed on the market by a well known firm of chemists.

April 22, 1915.

The German Physician and the Therapeutic Springs of France.—Kionka writes in the interest of German subjects who have made free use of certain foreign springs either by personal visits or through the use of the exported waters. Nonmedicinal table waters may be excluded from consideration. Of medicated French waters the chief demand has been for Vichy and Evian. The alkaline waters of Vichy have but relatively little carbonic acid gas, and are therefore less palatable than some of the German carbonated waters, and can readily be replaced by the products of the springs at Fächingen, Ems, Salzbrunn, etc., whose composition resembles that of the Vichy waters, and notably the former. The waters at Evian contain alkaline earths chiefly, and the total mineralization is small, as is also the amount of contained gas. Until recently these waters had no German counterpart, but in 1910 similar waters were found in South Germany in a spring now known as the Bissinger-Auer. These have a total radioactivity of 3.8 Maché units, due to the presence of radium emanation. A large quantity of gas escapes from these springs, which consists chiefly of nitrogen (84 per cent.). Oxygen is

represented by 9.5 per cent., and carbonic acid by 1 per cent. The remainder consists of the so-called "noble gases," by which term is implied the substances helium, neon, argon, crypton, xenon, in addition to radium emanation. These gases are given off at the rate of 33 minute liters.

Recent Foreign Remedies and Specialties, etc., in Germany.—Zernik takes the opportunity of informing the profession that certain imported popular remedies are really by no means what they are represented to be. Naturally certain American proprietaries have been sufficiently exposed by our own analysts. A well-known digestive tablet, for example (ethically marketed), contains sodium bicarbonate and charcoal, but no enzyme. A so-called "bromo-quinine" of English origin, which also has laxative properties, consists of phenacetin and jalap. A well-known English "fruit salt" is an effervescent preparation of tartaric acid and soda. French secret remedies are attacked by wholesale. "Kola" preparations contain no kola, but in some cases caffein. A gout remedy is alleged to contain "crystallized" colchicine, but this substance does not crystallize. The pills are no more than ordinary 1-grain colchicine pills. An alleged nutritive phosphorus preparation for children, sold at a high figure consists of phosphate of lime, starch, sugar and cocoa. Various sandal-wood preparations sold at a high figure are no more than ordinary sandal-wood capsules. Fancy, high-priced preparations of menthol, sold under various names, preparations of tamarinds, cacodylates, glycerophosphates, all can be dispensed cheaply by chemists who know the formulæ. A French apiol preparation is evidently an exception to the preceding, as it represents a valuable trade secret. The German chemists have been seeking a logical substitute, as a particular botanical source was evidently concerned in the French preparation. Thus far they have been unsuccessful.

Treatment of Subacute and Chronic Eczema with Filtered Röntgen Rays.—Meyer, at the close of a long article, hopes that he has demonstrated the superiority of hard filtered rays over the medium rays for these conditions. Results are more prompt, certain, and regular, doubtless because of a higher biological efficacy. No longer can from 7 to 7.5 Wehnelt units be considered the ideal radiation for skin diseases, for the author obtained his results with 10 and 11 units. The filter was an aluminum plate 1 mm. in diameter and the focal distance invariably 20 cm.

April 29, 1915.

Bread and Its Properties.—Rubner states that the daily bread problem is today one of the most important for the whole of Europe, not only for militant but for neutral nations. Everywhere there is difficulty in obtaining grain as a result of the disturbances of commerce. Bread grain is such a necessity that diminution of the regular supply is to be regarded as a serious danger. The ancient Germans raised oatmeal and barley originally. The cultivation of wheat came from the Galls on the west, that of rye from the Slavs on the east. The exotic grain was purchased both in bulk and seed. France as well as England have been wheat eating countries. No countries, in fact, can be termed rye countries; but rye is cultivated wherever it yields a more profitable return than wheat. Those who raise rye as a business proposition may, however, prefer wheat for its greater palatability. The making of bread is not as primitive and universal a condition as is usually believed. It is first heard of in Egypt, from which country the Greeks borrowed the art of baking it. The custom had reached Rome 168 B.C. Defining bread as baked fermented dough, it may be said that from the three countries mentioned, the consumption of bread has spread over the entire world. For many centuries bread cereals consisted exclusively of wheat and rye. Attempts to introduce other kinds of grain for permanent use were always failures. Even at present the use of wheat and rye bread is still being diffused through the world. These cereals are by no means of equal food value, for wheat flour is rich in gluten in available form. Rye gluten cannot be kneaded out of rye meal. Meals of this type are beaten rather than kneaded before baking. Another property possessed alone by wheat bread is that of forming a light crumb, and this in turn is due to the condition of the gluten in the dough. Good bread never goes out of use, one never gets tired of it, and it can be consumed continually every day of the year. When we speak of white bread we refer to that made of flour so fine that it can be passed through meshes 0.1 to 0.2 mm. wide. However, in the consumption of bread as a whole milling plays an enormous rôle in comparison with earlier years in which simple flat millstones were alone available. Grain can be milled in numerous ways and degrees. The whole grain meals furnish various breads, long in use, which while popular with many people and communities, are highly indigestible, and hence of relatively low nutritive value. By keeping the bowels open, however, they acquire the reputation of being salutary. Most of these breads are made from rye, pumpernickel being one of the best known. The first step toward fine milling was decortication of the outermost envelope, something which should be done at least in the interest of sanitation, as the outermost hull is filled with dirt and has besides little or no nutritive value. Flour and bran may be separated completely, and the bran subjected to various degrees of milling. In whole wheat the greatest available percentage of wheat is 75 per cent., while in the decorticated grain this figure may reach 96 per cent. For over thirty years the author has studied the problem of the utilizability of bran, with reference to the limits of use of whole grain flours. Bran alone can be ground exceedingly fine, but when whole wheat is ground the bran cannot be ground as fine as the wheat kernel. Separate bran has to be washed very thoroughly before milling. The question of utilizing the bran is one of great moment, and the finest milled bran when mixed in a certain proportion with the wheat flour proper should conserve to the bread all its original utilizable ingredients, while not interfering with its digestibility to any appreciable extent.

Value of Insect Powders.—Lehmann writes in the interest of the vast problem of the prophylaxis of typhus fever through warfare against the clothes louse. Immense quantities of insect powder have been and are being used for this purpose. The term insect powder is of course vague. Many pollen grains are always present and it is not difficult to count them. According to the number present we may judge of the quality of the powder. Microscopial and chemical studies show that first-class material should have 2000 granules of pollen for each mgm. of powder. This means that the powder is prepared from closed buds which contain all the pollen of the bud. If from 1000 to 2000 pollen granules are present the powder has been made from half open buds. If only 500 grains are present a large amount of inert matter from the bottom of the bud or the twig itself is present.—*Münchener medizinische Wochenschrift.*

Insurance Medicine.

THE GENERAL FACTORS DETERMINING MEDICAL SELECTION.

FROM "ALLGEMEINE LEBENSVERSICHERUNGSMEDIZIN" BY PROF. DR. GEORG FLORSCHÜTZ OF GOTHA.

(*Continued from page* 1001)

THIS objection *per se* seems well founded. For the expansion is the difference between the least chest measure during expiration and the greatest chest measure in inspiration, and consequently if we leave out of count the diaphragm it is the expression of the breathing power of the applicant. The more extensive the work of the thorax, and therewith the greater the difference, the more abundantly are the lungs provided with air, and, according to our biological views, the less is the danger of a disease.

Life insurance practice nevertheless does not support this assumption. It is not only not rare but indeed common to find in a tuberculosis loss that the applicant had a very good expansion, while conversely risks with small expansion survive. The explanation of this apparent paradox is not difficult to give. The expansion is brought about practically altogether by inspiration, which is effected by elevation of the ribs and sternum. Now, the simplest observation of insured material teaches at once that the volume of inspiration stands in proportional relation to the height; or, in other words, the taller the man the greater, *ceteris paribus*, his expansion.

While tall subjects may have a chest expansion of 8 to 10 cm. (3 1/5 to 4 in.), the average being between 6 and 7 cm. (2 2/5 and 2 4/5 in.), short subjects seldom attain an expansion of 7 cm. (2 4/5 in.), and the average does not reach 5 cm. (2 in.). These differences are due to the fact that in the tall the ribs are wider apart and the intercostal spaces are broader, so that thoracic movement may be more extensive than in short people, where conditions are reversed. The thoracic relations which are peculiar to tall subjects are, however, those which characterize the thorax paralyticus, so that it is not surprising that in this condition also expansion can attain great limits—but only *can*, and therein lies the characteristic which separates the two. For how is inspiration effected? Solely through the power of the inspiratory muscles and upon their efficiency depends the aeration of the lungs. In the habitus paralyticus, however, in conformity with the condition of the general strength, the efficiency is quite notably depressed, and for this depression the maximum inspiration-circumference demanded and established by the examining physician is no measure at all. With great effort the subject examined can reach a wide inspiratory position—because the requirements are all present, and despite the ossification of the thoracocostal joints which play so large a rôle in the etiology of tuberculosis, he can make a great inspiratory effort —but only one; for as a rule the inspiratory excussion is slight, the respiration being superficial.

Hence the chest expansion found by the medical examiner and indicated in the application is only a delusion. The laity make the effort during examination to "throw out a chest," and if life insurance placed a special value on the exact determination of the expansion the single measurement of the volume of respiration now required would be the most useless procedure imaginable.

We only refer in passing to the extremely slight chest expansion of women. Despite this, they do not die of tuberculosis more frequently than men. We cannot admit the etiological significance in tuberculosis of the shortening and premature ossification of the cartilage of the first rib, as described by Freund, nor the reduced excussion of the sternal angle. In any case it is not the local alterations but the constitution as a whole, which will determine the selection.

We must again say a few words regarding the infection of tuberculosis. We have already said above that it is very seldom actually observed in life insurance medicine, and that in 1428 deaths from tuberculosis there were but 11 instances in which the wife developed the disease. In like manner, Mollwo found among 1244 cases of tuberculosis in the Lübeck Life Insurance Company but 5 cases in which the wife was infected, and Runge obtained similar results, based on an investigation which he instituted with the material of the Nordstern Life Insurance Company. (*Zeitschrift für die gesamte Versicherungswissenschaft*, 1906, No. 4.) But the insignificance of marital infection is shown in another way. Thus, Thorn in the statistics of the Hohenhonnefer Company, found 3 per cent., Jacob and Pannwitz 3.4 per cent., and Haupt 5 per cent., while, conversely, Cornet could show such infection in 23 per cent., and Elsaesser in 39 per cent. The difference in these figures, however, is at once explained when one takes into consideration the composition of the material from which the percentages were obtained. The small figures came from sanatorium patients of the well-to-do classes, while the large percentages came from the lower classes.

Weinberg has very thoroughly investigated the subject of consumption in married couples. (*Beiträge z. Klinik d. Tuberkulose*, 1907), supporting himself upon the observations made in Stuttgart during the years 1873-1902 on the survivors of those dying of tuberculosis. He did not content himself, like the statisticians just named, with simple enumeration of cases, but put to himself the question whether the mortality of the survivors was essentially higher than the tuberculosis mortality of the population as a whole. He found that the mortality was indeed twice as great as general experience could expect; but only ¼ of the women and 1/3 of the men could have been infected from their spouses. For the rest the women, after the death of their husbands, lived under unfavorable economical conditions, especially as regards housing. Then, grouping his material according to the social position of the dead, he obtained the following gradations: Upper classes, 69 per cent.; middle classes, 184 per cent.; lower classes, 235 per cent. Weinberg thereby confirmed the axiom (to be discussed elsewhere) that tuberculosis is a disease of habitations, and that life insurance need not fear direct transmission, provided the external conditions of the matrimonial survivors are favorable and the predisposition is lacking.

Thus far we have shown what importance is to be imputed to the constitutional factor in the selection of tuberculosis. Not so simple is it to establish its relations to those diseases in which we have to deal not with an infection, nor with the penetration into the body of a microorganism, but with one of those many sided disturbances of metabolism (diatheses) or a definite organic disease. That hereditary processes are of importance here is taught by statistics already cited, but here again it is not the disease but the predisposition which is inherited.

(*To be continued.*)

Book Reviews.

TEXT-BOOK OF SURGICAL OPERATIONS, ILLUSTRATED BY CLINICAL OBSERVATIONS, FOR PHYSICIANS AND STUDENTS. By Prof. FEDOR KRAUSE, Privy Medical Councillor, Directing Physician Augusta Hospital, Berlin; in Association with EMIL HEYMANN, M.D., Chief Physician, Augusta Hospital. Translated into English and Edited for American Readers by ALBERT EHRENFRIED, A.B., M.D., F.A.C.S., Assistant Visiting Surgeon, Boston City Hospital; Junior Assistant Surgeon, Children's Hospital; Surgeon, Boston Consumptives' Hospital; Assistant in Surgery, Harvard Graduate School. In six volumes. Vol. I, 267 pages with 55 plates, having 233 illustrations in two or more colors and 61 figures in the text. Price, cloth, $6.00. New York: The Rebman Company, 1915.

THIS is the first of six volumes which are designed to cover the entire range of surgical operations. From the preface by Krause we find that the purpose of the work is to offer every properly trained physician a foundation upon which he can independently undertake the operations described; and in order to fulfill this purpose in all its details, pictures true to nature, explaining the different phases of each operation have been liberally supplied on special plates. He also states that the work not only includes all departments of surgical therapy but takes up systematically the surgical affections in the manner in which they are considered in the lecture room. Upon looking through this first volume we find that it gives every promise of successfully accomplishing this end. The operations are clearly described and the various steps adequately illustrated, while innumerable cases are cited to show methods of diagnosis and the type of operation suited to the individual case.

Upon reading the translator's preface, however, we find that the work has lost a large part of the authoritativeness of the original German edition; for although Ehrenfried says that in this American adaptation he has attempted first of all to give an accurate transcription of the German text, even at the expense of fluency, he also says: "I have modified and rearranged freely wherever it seemed advisable. Where German practice differs from ours I have entirely rewritten sections and paragraphs. Technical and controversial discussions have been abridged; *new matter, illustrations, and cases have been added.* To avoid complicating the text *no attempt has been made to distinguish the alterations and additions.*" (Italics ours.) To the mind of the reviewer this seriously detracts from the value of the work. We are interested in knowing *Krause's* methods, and prefer to use our own judgment in the selection of his or American ways of doing things, rather than have an Americanized version thrust upon us. It is evident that one must often be in doubt as to whether the advice given conforms to the teachings of Krause or his translator and editor, and this we believe to be a great mistake. With no intention of making invidious distinctions as to the relative worth of their contributions, we feel that all alterations or emendations should be clearly indicated; that if this had been done the value of the work would have been increased many fold, and that this course should be rigidly followed in the preparation of the remaining five volumes of the series. As the text now stands, some parts are manifestly from the pen of Krause and some as clearly contributed by Ehrenfried; but there is a considerable percentage where exact authorship is indeterminate.

In spite of this fact, the work deserves high commendation. The chapters on general surgical technique and the portion devoted to such of the operations on the head, face, eye, ear, nose, accessory sinuses, and nerves as are covered in this initial volume are exceptionally good; and we feel that succeeding volumes, if exact authorship of all statements is made evident, promise to be well nigh invaluable.

LEHRBUCH DER SPEZIFISCHEN DIAGNOSTIK UND THERAPIE DER TUBERKULOSE FÜR AERZTE UND STUDIERENDE. By Drs. BANDELIER and ROEPKE. Eighth edition. Price, Mk. 8.80. Würzburg: Curt Kabitzsch, 1915.

THIS is the eighth edition of Bandelier and Roepke's celebrated textbook on specific diagnosis and specific therapeutics in tuberculosis. The admirable introduction by Koch, which accompanied the fifth edition, is again reproduced. Compared with former editions the book is increased by one-third in volume and a few more temperature charts are added. The first portion of the work is consecrated to the theories of tuberculin reaction and its influence as a specific means of curing tuberculosis. All the various diagnostic methods, such as the cutaneous of von Pirquet, the percutaneous, the intracutaneous, the conjunctival, and subcutaneous way of introducing tuberculin are carefully described. It is refreshing to read in this edition a protest against the ophthalmic method devised by Calmette. The authors base their objection on the uncertainty of the ophthalmic reaction on the one hand and the likelihood of serious complication arising from the tuberculin instillation on the other. The modification of the conjunctival test recommended by Wolff-Eisner, which consists in the replacing of the solution by a tuberculin ointment, received equal condemnation from the authors.

In the chapter on specific therapeutics all the numerous culture products which are and have been in use are enumerated, including the Friedmann product and also that of Carl Spengler, known as "I K" (meaning "Immune Koerper" or immune bodies). Those interested in the value of these respective methods are advised to read carefully the tabulated results of the extensive observations of Drs. Bandelier and Roepke. For those unfamiliar with the German language it may be stated here that a former edition was translated into English by Wilfred B. Christopherson, is entitled "Tuberculin in Diagnosis and Treatment," and published by William Wood & Co., New York, 1913. This American edition is more condensed, which would seem rather an advantage. The conclusions as to the therapeutic value of tuberculin at which the authors arrive and of which they speak very fully in their final chapter are those characteristic of all tuberculin enthusiasts. The claim is set forth by them that there has not been a single case treated with tuberculin which resulted to the detriment of the patient when the injections have been made carefully and according to what the authors call the "mild method." As a whole the book deserves to be ranked as one of the best expositions of our present knowledge of specific therapeutics of tuberculosis.

LEGAL PRINCIPLES OF PUBLIC HEALTH ADMINISTRATION. By HENRY BIXBY HEMENWAY, A.M., M.D., formerly Health Officer of the City of Kalamazoo, Mich.; Secretary Kalamazoo Board of United States Examining Surgeons; Acting Professor of Preventive Medicine, College of Physicians and Surgeons, Chicago; author of a considerable number of articles on topics relating to preventive medicine or governmental problems. With an Introduction by JOHN HENRY WIGMORE, Professor of Law in the Northwestern University; Commissioner on Uniform States Laws, etc. Chicago: T. H. Flood & Co., 1914.

THE author of this timely volume is a remarkable instance of a medical practitioner versed in the law. His varied experience in public-health work has familiarized him with the legal aspects of preventive medicine, and he is thus particularly fitted to set forth the guiding principles that must decide the application of our governmental ideas to the facts of science in this field. Modern science has vastly enlarged the scope of modern law, and the question has come up whether the old and settled principles of the law will serve to deal with new conditions. We have reached a period when readjustment is demanded between the law and medical science. It is with the idea of assisting science and law to this better initial understanding that the author of this work discusses the relationship of public health to the body politic, the underlying principles of government, and the relation of the executive, the judiciary, and the police power to public-health administration. He describes "due process of law," "nuisance," and public-health powers and limitations, national, state, and municipal. He discusses the standing of the health officer in relation to the law, liabilities, and the legal remedies. In addition there are chapters on vital statistics, quarantine, medical licenses, water supplies, sewage and garbage disposal, pure-food and drug regulations, school inspection, and eugenics.

The book is clear, practical, well balanced, and should prove of great value at a time when many states are rushing into much ill-advised legislation on public-health questions. Although the legal part of the text may seem rather rudimentary to the lawyer and the medical portions somewhat trite to the sanitarian, yet every lawyer, judge, and health officer should read and ponder every chapter. The author admirably fulfills his purpose of finding a common meeting-ground for the legal and medical professions.

THE CARE OF THE SICK ROOM. By ELBRIDGE GERRY CUTLER, M.D., Cambridge: Harvard University Press, 1914.

THESE lectures were delivered at the Medical School of Harvard University and are edited by Dr. Bradford, Dr. Ernest, and Dr. Cannon. The little book will serve as aid for the nurse and family of a chronic invalid whose room has to be prepared in town or country.

THE QUESTION OF ALCOHOL. By EDWARD HUNTINGTON, WILLIAMS, M.D., formerly Associate Professor of Pathology, State University of Iowa; Assistant Physician in the New York State Hospital Service. Price, 75 cents. New York: The Goodhue Company, 1914.

THE author remarks that this pamphlet is the result of an investigation on the alcohol question undertaken for THE MEDICAL RECORD. Its tone is generally impartial and judicious, and the author's freedom from fanaticism may be seen from his advocacy of a club as substitute for the saloon in which it may perhaps be necessary to serve malted beverages as well as "soft drinks." The good results of such tempered methods have been seen in the Continental café system, where gross drunkenness is certainly less common than in the Anglo-Saxon countries.

THOMAS SHORTT (Principal Medical Officer in St. Helena). With Biographies of Some Other Medical Men Associated with the Case of Napoleon from 1815 to 1821. By ARNOLD CHAPLIN, M.D., (Author of "The Illness and Death of Napoleon."). With two portraits. Price, 2 shillings. London: Stanley Paul & Co., 1914.

THESE biographies all dwell on the fact of the concealment by the authorities that Napoleon really died from enlarged liver due to the St. Helena climate. Shortt fell into disgrace with Sir Hudson Lowe for expressing views unfavorable to the salubrity of the climate, James Roche Verling was dismissed because he stated that Count Montholon's illness was due to a pain in the liver and to an intermittent fever, and Alexander Baxter and Archibald Arnott received their M.D. degrees at Edinburgh later on from theses on "De Febre Remittente." In view of these curious facts, Barry O'Meara's report that Sir Hudson Rowe remarked that it would be better for Europe if Napoleon died no longer seems a calumny.

DISSECTION METHODS AND GUIDES. By DAVID G. METHENY, M.D., L.R.C.P., L.R.C.S. (Edin.), L.F.P.S. (Glas.) Associate in Anatomy and for some time senior demonstrator in the Daniel Baugh Institute, the department of Anatomy and Biology, Jefferson Medical College, Philadelphia. Octavo volume of 131 pages; illustrated; cloth, $1.25 net. Philadelphia and London: W. B. Saunders Company, 1914.

THIS book is a manual of local dissections in which both the external structures and viscera are dealt with. As it is intended for actual use in the dissecting room but 12 (schematic) illustrations are incorporated in the work. The small compass of the text is due to the fact that only the steps of dissection are described, with such regional anatomy as is comprehended in their results. Some of the regions involved are natural, some are artificial. All dissections are meant to be so carried out that no mutilation or waste results; they may, in fact, do double duty after preservation. Much of the dissection, especially that which results from exposing and isolating certain structures, must enter into the foundation of operative surgery.

CONTRIBUTIONS FROM THE THIRD DIVISION, NEUROLOGICAL INSTITUTE of New York, June, 1914.

THE contributions are fifteen in number and comprise papers and addresses most of which have already appeared in various medical journals. Both theoretical and practical topics are discussed. The attending physician of the Third Division is Dr. Pearce Bailey and seven of the articles are either by him individually or in collaboration with a colleague or assistant. The collection is chiefly of interest to the neurologist.

FOCAL SYMPTOMS IN GENERAL PARALYSIS. By C. MACFIE CAMPBELL, M.D., B.Sc., Associate Professor of Psychiatry, Johns Hopkins University, Baltimore. Price, $1.25 net. New York, Leipzig, London, Paris: G. E. Stechert & Co., 1914.

THIS is the author's thesis presented in July, 1911, to the University of Edinburgh for the degree of M.D. In it is taken the extreme view that, "In the discussion of the main issues, cases of general paralysis reported before 1900 should be used with the greatest reserve, even although the statement is made that the diagnosis was confirmed by post-mortem examination." Also, "One must accept with reserve purely clinical observations even if recent, especially if they do not include the examination of the cerebrospinal fluid; to publish as cases of general paralysis cases of atypical course, whether influenced by therapeutic measures or not, without an adequate examination of the cerebrospinal fluid indicates a want of realization of the difficulties of differential diagnosis." The author goes on to state that among the cases of general paralysis with atypical features and considerable diagnostic difficulties those presenting focal symptoms form a large group, and he subdivides them as follows: First, those cases of general paralysis with focal symptoms on the basis of vascular disorders; second, those on the basis of localized severity of the general paralysis process; third, cases of general paralysis with focal symptoms of traumatic origin; fourth, cases without clinico-anatomical correlation.

The bulk of the thesis is made up of carefully prepared histories of nineteen cases studied according to recent scientific methods. There are twelve photographs and microphotographs of pathological preparations. The clinical observations were made in the service of the Psychiatric Institute of the New York State Hospitals, and the autopsy studies and technical work were done in the laboratory of the institute. The monograph is very conservative and creditable. The writer acknowledges valuable assistance by his confrères of the laboratory.

NERVOUS AND MENTAL DISEASES. By ARCHIBALD CHURCH, M.D., Professor of Nervous and Mental Diseases in the Northwestern University Medical School, Chicago; Late Professor of Neurology in the Chicago Polyclinic; Neurologist to St. Luke's, Wesley and Mercy Hospitals; Consulting Neurologist for the Michael Reese Hospital, etc.; and FREDERICK PETERSON, M.D., ex-President of the New York State Commission in Lunacy; Formerly Professor of Psychiatry, Columbia University; Consulting Alienist, Bellevue Hospital; Manager of the Craig Colony for Epileptics, at Smyrna, New York; ex-President of the New York Neurological Society. With 350 illustrations. Eighth Edition, Thoroughly Revised. Price, $5.00 net. Philadelphia and London: W. B. Saunders Company, 1915.

THE popularity of this book, aside from its merits, may be considerably due to its convenience. It is unusual to find the correlated branches of medicine, neurology and psychiatry, each discussed by a separate writer, appearing in one and the same volume. Reviews of previous editions have already appeared in the MEDICAL RECORD. In the preface of this edition, it is stated that revisions have been made in the section on Nervous Diseases to the extent of 114 interpolations and over 200 minor alterations. The chief additions noted comprise Bárány's researches concerning vertigo and the vestibular apparatus; late important discoveries in relation to syphilis and the nervous system; new investigations of the spinal fluid; recent studies of infantile paralysis and the relationship of the glands of internal secretion to nervous disorders. There is no mention of revision of the section on Mental Diseases. Six hundred and seventy-six of the nine hundred and forty pages of the book are taken up by the neurological part. The style of both authors is clear and concise. The illustrations are numerous and good and the book is a valuable text book for the general practitioner.

PATHOLOGICAL TECHNIQUE. A Practical Manual for Workers in Pathological Histology and Bacteriology, including Directions for the Performance of Autopsies and for Clinical Diagnosis by Laboratory Methods. By FRANK BURR MALLORY, A.M., M.D., Associate Professor of Pathology, Harvard University Medical School; Pathologist to the Boston City Hospital; and JAMES HOMER WRIGHT, A.M., M.D., S.D., Pathologist to the Massachusetts General Hospital; Assistant Professor of Pathology, Harvard University Medical School. Sixth edition, revised and enlarged, with 174 illustrations. Price, $3.00. Philadelphia and London: W. B. Saunders Company, 1915.

THE sixth edition of this well known work has been improved by the inclusion of a number of the more recent methods, especially those for staining parasites in tissues, and of a number of new cuts, all of the same admirable quality which has characterized this exceedingly useful laboratory guide. It has been, and will probably long remain, the standard work on pathological technique.

Society Reports.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Annual Meeting, Held January 18, 1915.

THE PRESIDENT, DR. THOMAS S. SOUTHWORTH, IN THE CHAIR.

Election of Officers.—The following officers were elected: *Vice-President,* Dr. Edward E. Cornwall; *Corresponding Secretary,* Dr. Frank C. Raynor; *Treasurer,* Dr. Isaac Hartshorne; *Chairman for the Borough of the Bronx,* Dr. Nathan B. Van Etten; *Member of the Council,* Dr. Frank H. Daniels.

The Tuberculosis of Migrants.—Dr. CHARLES E. WOODRUFF, Lieutenant-Colonel Medical Corps, U. S. A., retired, in this paper said that for the explanation of the ethnic phenomena of tuberculosis death rates it was immaterial whether we accepted the view that infantile infection is harbored throughout life or that the individual succeeds in overcoming this, to be later reinfected. The facts were better explained by considering that some always harbor their latent lesions, which spread with greater or less rapidity according to the damage sustained from the climate; but we might also consider that they have become susceptible to reinfection. His attention was first directed to this matter in 1899 by the appalling rapidity of tuberculosis among our soldiers in the Philippines, where there was a climate which was ideal according to the theory prevalent at that time, and still held by many physicians. The temperature was equable, there was a maximum of sunshine, and everyone lived outdoors. An order was issued to send cases home by the first boat, as a delay of a single month in getting to a cooler, darker climate would be fatal. The patients would get well if sent home in the early stages, or even after bacilli were found in the sputum. To explain the matter we had to go back to the basic principle of biology, the law of adaptation to environment. While the characteristics of plants and animals were found to be evolved by the survival of the fittest variations, for a long time man was excepted from this universal law because he was not immediately killed after migration to an unfit climate. If the damage were slight, a type might survive for many generations, or even centuries. If variations appeared which were of survival value, these would survive while the rest perished and in this way many localized types had been evolved after migration from the cradle of the race. A recent discovery of great importance was that adaptation to the environment must be much more exact than had been thought necessary for permanent survival. A type evolved in one environment must, then, always be more or less injured in any other, and the greater the difference between the two, the greater would be the mortality rate, age for age, and the shorter the average age as compared with the same type in its place of origin. It was quite evident that tall men who migrate to lands of small stature should suffer more from tuberculosis than the short migrants. He had frequently noticed this among Americans in the Philippines, and he had also found that stout and muscular men, particularly athletes who exposed themselves to the sun, would occasionally develop tuberculosis. The native or adjusted physique was frail, and the small American brunettes did not furnish many cases of the disease. Blonds were particularly harmed in all light climates where the heat was above the critical temperature for long periods. Such were out of adjustment, and the course of tuberculosis was apt to be exceedingly rapid in them, as he had observed in the Philippines. In the Phipps Institute, of Philadelphia, the third annual report showed that of 725 consumptives, 371 had light eyes; and this in a city population notoriously brunette. In the Agnes Memorial Sanatorium in Denver there were, according to its report, 152 blonds to 44 brunettes. The Hebrews of New York and Boston had lower tuberculous rates than any other racial element of the population, yet they showed the universal phenomenon of elimination of the lightest, many of whom were perfectly adjusted to the darker and cooler cities of Europe. The race was notoriously dark, with only a few blonds, yet Rosenberg had reported that at the Montefiore sanatorium there were 417 light types and 733 dark, the "light" class including all variations from the prevailing brunetteness of the race. Moreover, cases in the few real blonds among them were said to be rapid, hemorrhagic and incurable, while those in patients of the ordinary complexion were slow, mild and curable. On the other hand, Shrubsall reported the greater tuberculosis mortality of the brunettes in those places in northern Europe where the blonds were the adjusted types; and this was more marked the blonder the population, and therefore the greater the unfitness of brunettes. In all parts of the United States the blonds were the unadjusted, and, while few statistics were available, it had been proved conclusively that blonds furnish more than their share of cases of tuberculosis, and are more difficult to cure. This phenomenon was more marked in the South, where also there were the highest tuberculosis rates in the country. The twelfth census showed that the death-rates from the diseases of the various races in the United States are approximately proportionate to their blondness. The climate of Ireland differed markedly from that of any part of this country except the extreme northwest coast. There had never been any selection of those fit for the extremes of heat, cold, light, darkness, or dryness met with here, and as a result some types of Irishmen who had been evolved as the fittest for Ireland were proving the unfittest for America. According to the census mentioned, the general death-rate and the death-rates from tuberculosis and alcoholism, for all over fifteen years of age in the registration area, were higher for those having Irish-born mothers than for any other division of the white population; while in New York City in 1906 the Irish death-rate from consumption was 476 per 100,000, or almost exactly double that for all classes. Italians, being from similar latitudes, had only a slightly higher rate than the average, in spite of their well known poverty and unhygienic and insanitary habits. Having referred to various other races, the speaker said that the tuberculosis mortality for each nationality varied little from year to year in New York. This was not temporary and accidental, but a permanent vital phenomenon, constantly eliminating the unfit among the newcomers. In a few generations, however, the survivors should show marked differences in the way of lessened mortality. Phthisiographers had once lauded climate as an essential in treatment, but the numerous failures in "good" climates and success in "bad" had caused some to change to the equally erroneous opposite extreme that no particular climate was needed for any case. In spite of this, a few still talked of the ideal climate with a maximum of sunshine; yet Dr. J. E. Stubbert mentioned that in his wanderings for the ideal climate he met with a place in China where the sun shone for five minutes in twenty-eight days, and intimated that he improved there. Each climate on earth was ideal for the type adjusted to it by ages of survival of the fittest, and harmful for every other type. Our eastern climates killed the tuberculous negro, but he got well if properly treated outdoors in hot, sunny places; while a tuberculous European promptly died outdoors in Central Africa. The practical point was that we must study the kind of man the disease had got, as well as the kind of disease the man had got. We could not send every case to the same place. Southern California was like Southern Italy, and it was reported that the Mediterranean type of man (the short brunette) furnished a higher proportion of cures there than any other. On the other hand, physicians of the rainy northwest coast had stated that an Italian who had progressed to the point of having bacilli in his sputum had never been known to recover there. It was to be greatly regretted that the reports by managers of sanatoriums did not go into this matter more fully, and describe the type of physique with which they had the most success. Rollier was the only one who had done this, and he had stated that his sun-baths injured the blonds who would not tan—a thing which might have been predicted. It was equally safe to predict that bulky patients as a rule would do better in cold climates, and the thin and frail in warm; while high altitude races should not be sent to the lowlands.

Dr. MAURICE FISHBERG said he thought Dr. Woodruff's contention that particular attention must be paid to the complexion as influencing the adaptability of the individual to certain climates required further confirmation. If we analyzed the conditions at the two sanatoriums mentioned, it would be found that the Agnes Memorial derived most of its clientèle from Americans of the middle class, who were mostly blonds. As to the Phipps Institute, it was not stated whether it was the hospital proper or the dispensary department which was referred to. If it were the former, the pre-

ponderance of blonds would be accounted for by the large number of Americans treated. All over the world it had been observed that tuberculosis went hand in hand with the time a people had been exposed to the disease. In remote South Sea Islands, where it had been previously unknown, tuberculosis became established and made havoc among the population after the whites came and brought the disease with them. The same had been true in the Philippines. Peoples which had been exposed for a long time to tuberculosis adapted themselves, not only to the country, but to the disease. Thus, the Jews, among whom, as had been remarked, the mortality from the disease was small, had been exposed to tuberculosis for two thousand years. The disease was always very fatal when implanted on virgin soil. The Italians, being almost all brunettes, should, according to Dr. Woodruff, be comparatively exempt; yet it was a fact that of the Italians returning from this country to their native land, from one-fourth to one-third were the subjects of tuberculosis. In Sicily, which had formerly been comparatively free from the disease, tuberculosis had in the last ten years become prevalent in consequence of the return of tuberculous emigrants from the United States and South America. So, while a great deal might be said concerning the matter of complexion, there were many other factors to be taken into consideration. This problem of tuberculosis was really a sociological one.

Dr. Woodruff said he hoped the impression had not been gained from his remarks that the physical type was of more importance than other causes in the production of tuberculosis. As he had endeavored to point out, it was only one of a thousand factors. Still, it was one which we must take into consideration in studying this subject. It was a fact that in slavery days tuberculosis had been very rare among the negroes of the South. This was because they were well taken care of, just as highly-prized domestic animals were, by their masters, to whom their death would have been an economic loss. As soon as they were free, however, and had to shift for themselves, tuberculosis began to start up among them. Many persons had got the idea that the disease was peculiarly fatal to negroes, but this was not the case; for it had been demonstrated that under proper conditions it was just as curable as among whites. If the point raised by Dr. Fishberg were true, he could not for his part understand why in all the days of slavery the blacks should not have been more subject to tuberculosis, since they were in constant association with white people among whom the disease was more or less prevalent. Of all the tuberculosis curves which he had obtained in Paris, that of Ireland was the only one which went up. The disease had gone on increasing for twenty or thirty years, but about eight or ten years ago it began to decline, just as typhoid fever, the curve of which was parallel, did. Hoffman had stated that the good results noted from the campaign against tuberculosis were really due to the diminution of the diseases causing it. We knew that during the prolonged political agitation in Ireland widespread poverty and distress had prevailed, conditions favorable to the development of tuberculosis; but of late there had been increasing prosperity in the country, and in consequence the disease had steadily waned.

Treatment and Prophylaxis of Whooping Cough, Based on the Bordet-Gengou Etiology.—Dr. Paul Luttinger read this paper, reporting work which was part of an extensive investigation on the etiology, diagnosis and treatment of pertussis undertaken by the Bureau of Laboratories of the City Health Department in collaboration with some private practitioners. During the spring and summer of 1913 the Bordet-Gengou bacillus was found, at the City Research Laboratory, in the sputum of whooping cough patients with enough constancy to warrant the preliminary experimental trial by the Department of Health of the vaccine treatment of the disease. Although Bordet himself had not reported any success with specific therapy, there were several American clinicians who had obtained encouraging results with small doses of commercial pertussis vaccine. The speaker described the types of vaccine and the method employed in preparing the vaccines, and stated that the eight varieties made use of appeared, with one exception, to be about equally potent. The vaccines were given subcutaneously with an ordinary hypodermic syringe. The skin over the biceps was first rubbed with a piece of cotton soaked in alcohol, and if the needle had been sterilized there was no danger of infection. To infants, large doses might be given in the gluteal region. At the beginning an initial dose of 50,000,000 was given, and the dose was doubled every three or four days. Later, the initial dose was increased to 250,000,000, and the dose was doubled every other day, provided there was no reaction. For the purpose of prophylaxis three doses were given at intervals of three days, and these were respectively of 500 millions, one billion, and two billions. In nearly 3,000 injections given he had not observed a single severe reaction; it was well, however, to warn the parent against a possible local or slight general reaction. The preliminary series of cases numbered 107, in addition to 25 treated prophylactically, but the histories were complete in only 45. Of these patients, 60 per cent. had stopped whooping within one month. If Holt's figure of 30 days as the average duration of the paroxysmal stage were adopted, it would have to be conceded that these cases were only slightly, if at all, benefited by the vaccine treatment. It was a fact, however, that at St. Joseph's Orphan Asylum, where a portion of the cases were treated, some patients who had been given the ordinary whooping cough mixtures had been whooping for from 45 to 180 days, and in an epidemiological investigation made in the spring of 1914, it was found in the borough of Manhattan that the average duration of the whoop was two months. Thus, by comparison, some beneficial effect might be ascribed to the vaccine. The prophylactic cases were all at the asylum, and in none of them was the disease contracted except in that of a child who received one injection and refused to have any more. This experiment, however, lost a good deal of its significance on account of lack of information as to the exact time of exposure, and it could also be assumed that probably a certain proportion of the children were immune to the disease. In the summer of 1914 the Health Department, in order to secure more uniform views upon the subject, as well as more abundant material for bacteriological investigation, organized its whooping-cough clinic. Of the 376 cases treated at the clinic from August 10 to December 31, only a fraction were available for comparative study. Of all cases treated coming in with the diagnosis of pertussis, 17.5 per cent. were negative, this diagnosis proving upon further examination to be erroneous. The diagnosis of the discase was made on the evidence of the whoop with vomiting, and in doubtful cases this was confirmed by the isolation of the Bordet-Gengou bacillus from the sputum. A negative sputum, however, did not exclude pertussis. On account of other Gram-negative bacilli frequently found, one could not diagnosticate the disease from the bacterioscopic picture alone. The sputum must be planted on a special blood-agar-glycerin-potato medium, and other organisms having the same morphological and staining characteristics excluded. The complement-fixation test had not so far proved of any practical value in the diagnosis of pertussis for therapeutic indications. In over 100 cases studied at the Research Laboratory positive complement fixation was found in about 50 per cent., and not earlier than the fourth day of the paroxysmal stage—a time when anyone could make the diagnosis if it depended on the whoop. These negative cases were probably responsible for the extremes of opinion regarding vaccine treatment held by private physicians treating a limited number of cases. A child with a non-specific cough with regurgitation, which was magnified by an anxious mother into paroxysmal attacks with vomiting, was apt to improve "miraculously" after the second dose of vaccine, while one with a severe bronchitis simulating whooping-cough would of course wholly fail to respond to the treatment. There were 20 doubtful cases, and from the table, showing both vaccine and drug treatment, no definite conclusion as to the superiority of one over the other could be drawn. It was possible that some of these doubtful cases were abortive forms of the disease. Of 76 cases treated with drugs, only 35 had been tabulated, as in the others the whoop had at the time they came for treatment already lasted longer than in the average case. A basis for comparison with the vaccine cases had to be found, and, somewhat arbitrarily, 21 days was selected as the longest duration which would admit of comparative study. In the cases of less than three weeks' duration treated with drugs the average for the paroxysmal stage of the disease was found to be 40 days. In most of them antipyrine and sodium bromide were given, with an orange flower syrup as the vehicle. Of 138 cases treated with vaccines, 115 came under observation within the first three weeks of the paroxysmal stage. The average duration was 25

days, and this figure could have been much reduced if certain cases had been excluded: such, for instance, as that of a child with low resistance who had coughed for 84 days before the whoop commenced. It was brought to the clinic on the 21st day of the paroxysmal stage, and it whooped for 111 days; being finally discharged with an occasional whoop. On the whole, the vaccine treatment appeared to have shortened the paroxysmal stage, as compared with the drug treatment, by over two weeks; and of more significance was the prompt amelioration which had resulted in nearly all instances. In some cases, however, especially when a moderate reaction followed the first injection, a slight aggravation occurred during the first one or two days. In the cases treated with antipyrine, which showed, first, a decrease in the number but not the severity of the paroxysms, vomiting was apt to continue until or after the whoop stopped; both were apt to return as soon as the medicine was withdrawn or on the least provocation due to a new "cold," gastro-intestinal trouble, etc. Such relapses were rare in cases treated with vaccine. In only a few instances were more than three injections given. As a rule the mother would refuse further "needle treatment" as soon as there was a marked amelioration in the character and number of the paroxysms. Among the vaccine cases, four developed pneumonia, and three of these made perfect recoveries. The fourth contracted pneumonia after it had drifted away from the clinic, and died in a hospital. The only other fatality occurred in an infant with marasmus, which died six weeks after the treatment, from intestinal complications and pneumonia. Of 34 prophylactic cases tabulated, only 9 could be called strictly prophylactic (exposed to pertussis, but showing as yet no symptoms of the disease). The others had either a plain cough or a mildly paroxysmal one with vomiting, and to them the treatment was given with a view to aborting the disease, rather than preventing an infection which seemed to be already present. The 9 gave histories of exposure from one to fourteen days, and to date (from two to four months after immunization), all had remained without any symptoms. Of the remaining 25 cases, 19 patients stopped coughing during or soon after the treatment. In the other five the vaccine was not successful in aborting the disease, and one of these was the marasmus child who died. The following conclusions might be drawn from this work: 1. Pertussis stock vaccines, as prepared by the Bureau of Laboratories, seem to have a prophylactic value when given in a high dosage. 2. In the treatment of pertussis they seem to have shortened the duration and severity of the paroxysmal stage. 3. Further experiments, with the view of obtaining more effective vaccines and a closer cooperation of the profession in public health education, may help in the eradication of pertussis, this scourge of childhood which yearly kills ten thousand American children.

Dr. E. Mather Sill said that his experience with the vaccine had been limited to between sixty and seventy cases. In the matter of prophylaxis he believed that it would be of greatest value. As a prophylactic he had employed it in only ten cases, but none of these children, although exposed, developed the disease. In treating whooping cough with it he had not, in the beginning, paid so much attention to the age of the child as to the frequency and severity of the paroxysms. His dosage, in the majority of instances, was from 50,000,000 to 100,000,000; so that the young infants received a proportionately larger dose than older children, and it seemed to him that he obtained better results in these cases. The average time for a cure in his cases, after vaccine treatment was begun, had been from three to four weeks. He did not consider the vaccine a specific for the disease, but did believe that it was a great addition to our armamentarium in its treatment; in many cases diminishing the severity of the paroxysms and shortening the course of the disease to a greater extent than had hitherto been possible with drugs.

Dr. Alfred F. Hess spoke of the great advantages he had had personally in observing the effects of the vaccine, both therapeutic and prophylactic, from the fact that this occurred in an endemic in an infant asylum. He was thus enabled to have complete control of the cases to the end. Another advantage was that, in all probability, all the cases were due to the same type of bacillus. In the third place, no other medication was employed, while the conditions as to food, care, etc., were the same for all the children. Fourth, it was possible to know just when the disease began. In all, 85 children were treated. The treatment was commenced very early—sometimes on the second or third day—and two or three doses, of from 100,000,000 to 200,000,000, were usually given. Four different vaccines were employed, one of them autogenous, and it was not observed that the vaccine appreciably lessened the paroxysms either in number or violence. Of the 400 children in the institution, 244 had the vaccine administered to them prophylactically—in every instance before there was any sign of an attack—and 20 of them developed the disease. This seemed a fair result, though by no means as good as was ordinarily met with in antityphoid vaccination. From his experience in this epidemic the conclusion at which he had arrived was that pertussis vaccine is of no curative value, but is of some value as a prophylactic.

Dr. W. Morgan Hartshorn gave a *résumé* of the cases treated at the Roosevelt out-patient clinic, and stated that because of the unsatisfactory results observed the use of the vaccine had now been given up there. Up to the present it had seemed to him, he said, that the vaccine was not of much service except as a prophylactic. It had not as yet been proved that the Bordet-Gengou bacillus was positively the causative agent in pertussis, and there were various other microorganisms which might perhaps be concerned in its etiology. The Bordet-Gengou vaccine was uncertain, although with an autogenous vaccine we might combat the causative organisms, whatever these might be. The cases he had treated medically were always well, or nearly well, inside the six weeks limit which had been fixed upon at the clinic.

Dr. Luttinger said it could not be expected that results could be obtained from a vaccine equal to those from a serum such as diphtheria antitoxin. Still, he believed that the reason why some of the speakers had not secured better results was because they had not given larger doses. At the whooping-cough clinic it was customary to begin with a dose of 250,000,000, and in many instances with as much as 500,000,000. Therefore the results obtained appeared to depend somewhat on the size of the dose. As to Dr. Hess's cases, it ought perhaps to be taken into consideration that the children in infant asylums do not, as a rule, have as much resistance as others—not forming antibodies as readily. All that he had claimed was that the vaccine treatment gives better results than drug treatment, and it seemed to him that the results which had now been obtained at the clinic had shown that the vaccine favorably modifies the paroxysms, shortens the duration of the attack, and diminishes the mortality of the disease.

Pathological Society of Philadelphia.

At a stated meeting held May 13 Dr. Alfred Gordon presented a specimen of "Hydromyelia." The patient had been a young woman, 22 years old, in whom hydrocephalus had been observed since the age of 12. On post-mortem examination all of the cavities of the brain as well as the central canal of the spinal cord were found to be enormously distended.

Dr. George W. Outerbridge presented a specimen of "Adenoma Hidradenoides Vulvae," illustrated by means of lantern slides.

Drs. John A. Kolmer and Emery Marvel presented a specimen of "Multiple Intestinal Polyps, with Intussuception of the Small Intestine." The patient had complained of a good deal of abdominal pain and obstinate constipation, and with the development of symptoms of intestinal obstruction operation was performed and a segment of bowel removed.

Dr. John A. Kolmer presented a communication entitled "A Method of Transmitting Trypanosomes, with a Note on the Numerical Relationship of Trypanosomes to Infection." The number of trypanosomes was counted in a cubic millimeter of blood obtained from the tails of rats inoculated with trypanosomes by way of the peritoneum and by this means known grades of infection could be set up. It was found that the larger the number of trypanosomes to induce infection, the shorter was the period of incubation.

Dr. George W. Outerbridge presented a communication entitled "Non-teratomatous Bone-formation in the Human Ovary," illustrated by lantern slides. He had gained the impression from the literature that the occurrence of bone in the human ovary apart from such growths as dermoid cysts and teratomata was exceedingly rare, but observations directed especially toward this point seemed to show that the reverse condition may prevail, inasmuch as the examination of the ovary for ossification is not commonly made. He had

found such a condition present in not less than seven cases in the course of two years.

Dr. JOHN A. KOLMER, Miss MARY TRIST, and Dr. GEORGE A. HEIST presented a communication entitled "Complement Fixation in Intestinal Parasitism." It was found that in the presence of intestinal parasites the blood contained amboceptors and immune bodies with respect to preparations made from the respective parasites.

Dr. ROBERT A. KEILTY and Mr. F. E. PACKER presented a communication entitled "Experimental Studies on the Diffusibility and Bacterial Inhibitory Qualities of Various Antiseptics." The investigation was undertaken to determine the antiseptic activity of various drugs and their efficacy in the presence of wound infections. The most useful combination was found experimentally to consist of thymol and tricresol, 20 per cent., mixed with castor oil, white wax, and spermaceti.

Dr. G. K. STROBE read a paper entitled "Meckel's Diverticulum: A Resumé and Report of Four Cases of Acute Diverticulitis," with demonstration of specimens. He described the several varieties of diverticulum and the complications to which they may give rise, as well as the difficulty of differentiation of these especially from appendicitis, for which usually they are mistaken, the actual condition being discovered at operation.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

STATE BOARD OF MEDICAL EXAMINERS OF GEORGIA.

Atlanta, October, 1914.

ANATOMY.

1. Give origin and distribution of the facial nerve.
2. Describe in detail the humerus.
3. Give origin and insertion of the sartorius muscle.
4. Describe the palmar arch.
5. Describe the gall-bladder and give its relations.
6. Describe the popliteal space.
7. Describe the patella.
8. What is the function of the third cranial nerve?
9. Describe the prostate glands.
10. Where are the Peyer's glands situated?

PHYSIOLOGY.

1. Give the physiological composition of the blood and the function of each part.
2. Where are the red blood cells formed? Where the white blood cells?
3. From what do the new tissue cells originate in the process of repair?
4. What causes the (a) first sound of the heart? The (b) second sound? Locate the point of maximum intensity of each.
5. Give the distribution of the secretory fibers of the facial nerve.
6. How does the acidity of gastric digestion control the passage of food from stomach to intestine?
7. Describe the influence of hydrochloric acid on the pancreatic activity.
8. Give in detail the digestion of fat, stating the channel of absorption.
9. What proven function has the pituitary gland?
10. What effect has atmospheric pressure on respiration?

CHEMISTRY.

1. Name the elements constituting the chlorine group, also its symbol, atomic and molecular weights.
2. What are the symbol, atomic weights, and valence of bismuth and its physical properties?
3. Explain the terms anhydrous, deliquescent, and efflorescent.
4. What is the difference between calcium chloride and chloride of lime?
5. With what substance is calomel liable to be contaminated and how may this impurity be detected?
6. Of what four elements are organic compounds principally composed and name them?
7. What is an alkaloid and into what two classes are they divided?
8. What are the characteristics of the acidulous elements?
9. Describe the prominent symptoms of poisoning by digitalis and what treatment should be adopted.
10. What relation does apomorphine bear to morphine and how is it produced?

BACTERIOLOGY.

1. What is the relation of bacteria to disease?
2. What is the effect of temperature upon the growth and destruction of bacteria?
3. On what theory is tetanus antitoxin administered?
4. Describe in detail the bacterial findings in puerperal septicemia.
5. Give technique of the Widal test.
6. Describe the microscopic blood findings in a case of pernicious anemia.
7. Give most accurate method of determining the opsonic power of the blood.
8. Give average number of bacteria in each leucocyte.
9. Describe the best method of examination (microscopic) of sputum for the presence of tubercle bacilli.
10. What disease conditions are excited by gonococci?

ANSWERS.

ANATOMY.

1. The *seventh or facial nerve* has its superficial origin in the upper end of the medulla oblongata, in the groove between the olivary and restiform bodies. It passes "forward and outward to enter the internal auditory meatus; it lies upon a groove on the auditory nerve, with portio intermedia of Wrisberg between, and at the bottom of the meatus it enters the aqueductus Fallopii, along which it runs first outward between cochlea and vestibule as far as hiatus Fallopii; then backward in internal wall of tympanum, just above fenestra ovalis, at the turn presenting a swelling, the geniculate ganglion; and finally it passes downward, to emerge from the bone at the stylomastoid foramen; it then passes outward and forward in the parotid, dividing behind the ramus of the jaw into temporo-facial and cervico-facial branches, which further subdivide and intercommunicate, forming the pes anserinus."—(*Aids to Anatomy.*)

It *supplies* the muscles of expression in the face, the muscles of the external ear, the Platysma, Buccinator, Stylohyoid, and the posterior belly of the Digastric.

2. "The HUMERUS, or arm-bone, the largest and longest bone of the upper extremity, consists of a shaft, head, neck, greater and lesser tuberosities, and lower extremity.

The *shaft*, cylindrical above, flattened and prismoid below, becomes twisted in the middle, and presents: A rough triangular surface about the middle of its outer surface for insertion of the deltoid muscle, and a musculo-spiral groove for the musculo-spiral nerve and superior profunda artery, on each side of which arise the external and internal heads of the triceps muscle

The *upper extremity* presents—the head, forming nearly a sphere, projecting upward, backward, and inward, articulating with the glenoid cavity; the anatomical neck, immediately beneath, is slightly grooved for the attachment of the capsular ligament; greater tuberosity, external to the head and lesser tuberosity, with three facets from before backward for attachment of supraspinatus, infraspinatus, and teres minor muscles; lesser tuberosity, smaller but more prominent than greater, is anterior to head, for the subscapular muscle; bicipital groove, passes downward and inward between the two tuberosities and lodges the long tendon of biceps; the anterior bicipital ridge, bounds the groove in front and receives insertion of pectoralis major muscle; the posterior bicipital ridge receives the latissimus dorsi and teres major; the surgical neck, including the head, neck, and both tuberosities; a rough impression near the center of the inner border for the coraco-brachialis muscle; nutrient canal, below and toward the lower end.

The *lower extremity* presents from within outward the following: Internal condyloid ridge, extending upward from the condyle; internal condyle, more prominent than external, gives origin to the flexors and pronator radii teres; epitrochlea, an eminence separating the trochlea from the internal condyle; trochlea, a pulley-like articulating surface for greater sigmoid cavity of ulna; coronoid fossa, a small depression bounding the trochlea in front, and receiving the coronoid of the ulna in flexion; olecranon fossa, a larger depression behind, and receiving the olecranon process of ulna in extension; supra-trochlear foramen, sometimes formed by perforation of one fossa into the other; radial head, or capitellum, a smooth, rounded eminence articulating with cup-like depression on head of radius; external condyle, less prominent, gives origin to the extensors and supinators; external condyloid ridge, extending upward on the shaft from the condyle.

It *articulates* with three bones—scapula, radius, and ulna.

Its *muscular attachments* are twenty-five—subscapularis, supraspinatus, infraspinatus, teres major and minor, pectoralis majo., latissimus dorsi, deltoid, coracobrachialis, brachialis anticus, triceps, pronators and flexors to inner condyle, pronator radii teres, flexor carpi radialis, palmaris longus, flexor sublimus digitorum, flexor carpi ulnaris, supinators and extensors to outer condyle, supinator longus, extensor carpi radialis longior and brevior, extensor communis digitorum, extensor minimi digiti, extensor carpi ulnaris, anconeus and subanconeous, supinator brevis." (Young's *Handbook of Anatomy.*)

3. Sartorius. *Origin,* from anterior superior spine of ilium; *insertion,* into inner surface of upper part of shaft of tibia, behind the anterior tubercle.

4. The *superficial palmar arch* is formed by the ulnar artery, and is completed by the ulnar artery anastomosing with a branch of the radial (superficial volar or princeps pollicis). It gives off the four digital branches.

The surface marking is a line drawn transversely across the palm from a point where the web of the thumb joins the palm.

The *deep palmar arch* is formed by the radial artery, and is completed by the radial artery anastomosing with a deep branch of the ulnar. Its branches are the palmar interosseous, perforating, and palmar recurrent arteries.

The surface marking is a line drawn transversely across the palm, one-half inch nearer the wrist than the superficial arch.

5. The *gall-bladder* is a conical bag placed in a fossa on the under surface of the right lobe of the liver. Its upper surface is attached to the liver, and its fundus and posterior surfaces are invested by peritoneum reflected from the adjacent surface of the liver. The body is in relation in front with the liver, and behind with the first part of the duodenum, the pylorus, and the hepatic flexure of colon. The fundus is in contact with the parietes opposite the ninth right costal cartilage. It is about four inches long, and holds about one ounce. Its duct passes from the neck of the gall-bladder downward, backward, and to the left to join the hepatic duct.

6. The Popliteal Space is *bounded: Above, and externally* by the Biceps; *above, and internally* by the Semimembranosus and Semitendinosus; *below, and externally* by the Plantaris and external head of the Gastrocnemius; *below, and internally* by the inner head of the Grastrocnemius. *Contents:* Popliteal vessels with branches, external saphenous vein, external and internal popliteal nerves, small sciatic nerve, lymphatic glands, and loose areolar tissue.

7. The *patella* is a flat, triangular bone situated in front of the knee-joint; it is said to be a sesamoid bone developed in the tendon of the quadriceps extensor. Its anterior surface is convex and shows perforations for nutrient vessels; it is separated from the skin by a bursa. Its posterior surface is smooth and oval-shaped, and has two facets separated by a vertical ridge; these facets articulate with the two condyles of the femur. The superior border gives attachment to the rectus and crureus; the lateral borders give attachment to the vastus externus and vastus internus. The apex gives attachment to the ligamentum patellæ. The anterior surface is covered by the tendon of the quadriceps extensor, which is continuous below with the ligamentum patellæ.

It serves to protect the front of the knee-joint, and it increases the leverage of the quadriceps extensor muscle, by making it work at a greater angle.

8. The *third cranial nerve* is the motor nerve for the following muscles of the eye: Superior rectus, inferior rectus, internal rectus, levator palpebræ superioris, and inferior oblique.

9. *Prostate gland* is about 1½ x ¾ x ½ inches, and weighs about three-quarters of an ounce. It resembles a chestnut in size and form. It is situated at the neck of the bladder, and surrounds the first part of the urethra. It consists of fibromuscular (unstriated) tissue with imbedded follicular pouches, the whole enclosed in a firm fibrous capsule, continuous in front with the triangular ligament, and behind with the posterior layer of the deep perineal fascia. *Arteries* are from the vesical, hemorrhoidal and internal pudic.

Relations of prostate. *Anteriorly:* Symphysis pubis, anterior ligaments of bladder, branches of dorsal vein of penis. *Posteriorly:* Rectum. *Laterally:* Levator ani. *Base:* Surrounds neck of bladder, seminal vesicles, and vasa deferentia. The *apex* rests on triangular ligament.

10. *Peyer's glands* are situated in the ileum, with a few in the jejunum, and occasionally in the duodenum.

Physiology.

1. The physiological composition of the blood is: Plasma, red corpuscles, white corpuscles, and platelets.

The *function of the red blood corpuscles* is to carry oxygen from the lungs to the tissues.

The *function of the white blood corpuscles* is:—(1) to serve as a protection to the body from the incursions of pathogenic microorganisms; (2) they take some part in the process of the coagulation of the blood; (3) they aid in the absorption of fats and peptones from the intestine, and (4) they help to maintain the proper proteid content of the blood plasma.

The *function of the platelets* is not determined; it is possible that they take some part in the coagulation of the blood. In number they vary from about 200,000 to more than 500,000 in each cubic millimeter of blood.

Plasma conveys nutriment to the tissue; it holds in solution the carbon dioxide and water which it receives from the tissues, and takes them to be eliminated by the lungs, kidneys, and skin; it also holds in solution urea and other nitrogenous substances that are taken to and excreted by the liver or kidneys.

2. The *red blood cells are formed* in bone marrow; in fetal life they are formed in "blood islands," and in spleen and liver.

White blood corpuscles are formed in the spleen, lymph glands, and lymphoid tissue; also from other white cells by direct cell-division in the blood stream; the eosinophiles may be derived from the bone marrow.

3. "True regeneration may occur in bone, tendon, nerves, and striped muscle. . . . Exudation of plasma from the neighboring blood vessels occurs, and its fibrinogen is converted into fibrin, so glueing the edges of the wound together. Leucocytes are poured out and infiltrate the wound, absorbing any blood clot present. These are followed by fibroblasts (connective-tissue cells), which take their place. New capillaries form by budding out from adjacent ones, and vascularize the new tissue. Fibrous tissue is formed by intercellular exudation from the fibroblasts and so the fibrocicatricial union is complete, for at the same time epithelium is spreading over the narrow surface line."—(*Aids to Surgery.*)

4. There are two normal heart sounds which follow in quick succession, and are succeeded by a pause. The first, or systolic, sound is dull and somewhat prolonged, the second, or diastolic, sound is sharper and shorter. The sounds may be expressed by the syllables *lubb—dup.*

The first sound is heard best at the apex beat in the fifth left intercostal space; the second sound is heard best over the second right costal cartilage.

The *causes* producing the *first* sound of the heart are not definitely ascertained; the following are supposed to be causatory factors: (1) The vibration and closure of the auriculo-ventricular valves, (2) the muscular sound produced by the contraction of the ventricles, and (3) the cardiac impulse against the chest wall.

The *second* sound is caused by the vibration due to the closure of the semilunar valves.

5. The secretory fibers of the facial nerve are distributed (by the chorda tympani) to the submaxillary, and sublingual glands.

6. "After an ordinary mixed meal the pylorus usually opens for the first time about half an hour after digestion begins, and some of the acid chyme passes into the duodenum. The action of this muscular ring is intermittent, and the explanation of its alternate openings and closings may be briefly summed up in the phrase used by Cannon: "The acid control of the pylorus." It is necessary that the food should be retained in the stomach until it is acid; otherwise it would not, on reaching the duodenum, give rise to the formation of secretin, the chemical stimulus for the flow of pancreatic juice, and bile. He has found that acid on the gastric side of the pyloric sphincter opens it, and acid in the duodenum closes it. As soon therefore as the chyme is neutralized by the alkaline juices of the duodenum there is no longer any hindrance to the action of the acid chyme in the pyloric end of the stomach in opening the door which was temporarily closed by acid on its duodenal side. This action does not occur if a ring is cut through the muscular coat immediately beyond the pylorus, and so the effect from the duodenum is a local reflex action mediated like the movements of the small intestine by the plexus of Auerbach."—(*Halliburton's Physiology.*)

7. The acid in the gastric juice, when it reaches the duodenum, causes the production of secretin; this latter is absorbed by the blood and carried to the pancreas, where it incites pancreatic activity.

8. *Digestion of fats.* In the stomach, the gastric juice dissolves the connective tissue binding the fat cells together, and sets free the fat, which passes into the duodenum. Here the steapsin of the pancreatic juice (aided by the secretions) splits up the fats into glycerin and fatty acids.

Absorption of fat. "Fat is not absorbed as fat, but as glycerin and fatty acid or soap. It is generally accepted that the fatty acid set free in the intestine is dissolved by the bile salts, and in this way, together with the glycerin, is absorbed by the columnar cells, but that during absorption a lipase which is contained in the columnar cells re-synthesizes, by reverse action, the glycerin and fatty acid. In this way minute fat particles are found near the bases of the columnar cells, and these may be demonstrated by staining with a 1 per cent. solution of osmic acid. The fat globules are further taken up from the columnar cells by some of the lymphocytes, which are capable of exhibiting ameboid movements, and which are found in the lymphoid tissue between the columnar cells and the central lacteal. The fat is then deposited in the central lacteal by these ameboid cells, and in this way it gets into the general lacteal stream, and thence into the thoracic duct. The bile salts, which have been absorbed by the columnar cells, in all probability get into the portal vein radical, and in this way are taken back to the liver to be excreted again in the bile. After a fatty meal minute globules of fat may be demonstrated in the blood plasma of an animal; but they disappear rapidly, possibly existing in a soluble and invisible form absorbed to the blood proteins before they are deposited in the fat depots of the body."

9. *Function of the pituitary gland:*—"The *anterior* lobe is concerned with the process of growth, hypertrophy leading to overgrowth of the skeleton, and partial removal to failure of development of the body as a whole and of the sexual glands. Extracts of the *posterior* lobe, when injected into an animal, have a direct action on plain muscle all over the body; they cause constriction of the arterioles and a rise of blood pressure, contraction of the muscular coats of the digestive tract and of the bronchioles, and contraction of the uterus. The extracts also produce an increased flow of urine, which was at first attributed to the presence of a substance having a specific effect upon the renal cells; it is probable, however, that the diuretic effect is merely an indirect result of the more rapid flow of blood through the kidney which follows the injection of the extract. Extracts of the posterior lobe increase the secretion of milk, and after the injection a larger amount of milk is formed by the animal in the course of twenty-four hours." (Bainbridge and Menzies' *Essentials of Physiology.*)

10. Effect of atmospheric pressure on respiration. "*Effect of lowered pressure:*—When a person ascends from near sea level to a height of 5,000 to 10,000 feet or more, he is apt to suffer from symptoms which are generally described as mountain sickness: these symptoms are headache, mental confusion, blueness of the lips, and nausea or vomiting. They may occur when the individual ascends to this height in a train, and are therefore not due to muscular exercise, although they may become more severe when exercise is taken. They are caused entirely by lack of oxygen. With increasing altitude the barometric pressure, and therefore the partial pressure of oxygen in the atmosphere and in the alveolar air, gradually fall; and when the alveolar pressure of oxygen falls to about 60 mm. Hg. the symptoms just described make their appearance. Similar symptoms are produced in animals and in man, when they are placed in closed chambers and the barometric pressure is gradually reduced. If the individual remains at a high altitude, the symptoms pass off in the course of a day or two, and after a time exercise may be taken without their recurrence. The adaptation of the body to the altered conditions is brought about by changes in both the circulatory and respiratory systems. In the first place the lack of oxygen leads to the passage into the blood of lactic acid, which stimulates the respiratory center; and the breathing becomes deeper, with the result that the partial pressure of carbonic acid in the alveoli decreases and that of oxygen rises. At a high altitude, when the alveolar oxygen pressure is low, even a small rise in the partial pressure of oxygen appreciably increases the extent to which hemoglobin can be saturated with oxygen as the blood passes through the lungs. . . . Secondly, a more gradual compensatory process takes place in persons who remain at a high altitude for a long period. The number of red corpuscles and the percentage of hemoglobin in the blood are increased, and the oxygen-carrying capacity becomes much greater.

The *effect of raised pressure.*—Men engaged in the building of bridges and tunnels are often compelled to work in caissons, which are filled with compressed air to prevent the inrush of water. They suffer no inconvenience, and the respiratory movements are not affected while they are in the caisson, even though the pressure may be three or four atmospheres. Under this pressure, however, the blood dissolves an increased amount of oxygen and nitrogen, and when a man leaves the caisson, and the pressure to which the blood and tissue fluids are exposed is reduced to one atmosphere, most of the nitrogen, previously in solution, is evolved as bubbles, which may obstruct the flow of blood along the blood-vessels or through the heart. The symptoms caused by this obstruction, and known as caisson disease are very varied, and include paralysis, severe abdominal pain, and collapse. The disease is prevented by allowing the man to pass from the caisson into a special air chamber, in which the pressure is gradually lowered to that of the atmosphere so as to prevent any sudden evolution of nitrogen." (Bainbridge and Menzies' *Essentials of Physiology.*)

CHEMISTRY.

1. *The chlorine group:*—

ELEMENT	SYMBOL	ATOMIC WEIGHT	MOLECULAR WEIGHT
Fluorine	F.	19	38
Chlorine	Cl.	35.5	71
Bromine	Br.	80	160
Iodine	I.	127	254

2. Bismuth. *Symbol,* Bi; *atomic weight,* 208.5; *valence,* 3; *physical properties:*—A hard, brittle, crystalline solid; usually contaminated with arsenic; combines directly with chlorine, bromine, and iodine; is only slightly oxidized in cold air; it dissolves in hot sulphuric and nitric acids, becoming, respectively, a sulphate and nitrate.

3. An *anhydrous* substance is one that contains no water. A *deliquescent* substance is one that has a tendency to absorb moisture from the air. An *efflorescent* substance is one that, if exposed to the air, loses its water of crystallization and falls to powder.

4. *Calcium chloride* is $CaCl_2$. *Chloride of lime* is either $CaCl_2 + Ca(ClO)_2$, or $CaCl(OCl)$.

5. Calomel is liable to be contaminated with corrosive sublimate; the presence of the latter may be detected by the formation of a black stain upon a bright copper surface immersed in the calomel, moistened with alcohol.

6. Organic compounds are chiefly composed of carbon, hydrogen, oxygen, and nitrogen.

7. An *alkaloid* is an organic, nitrogenized, basic substance, capable of combining with acids to make salts in the same way that ammonia does. Alkaloids are divided into two classes: (1) Volatile and (2) fixed.

8. The acidulous elements do not form salts with the oxyacids, and their hydrates are acids, and their oxides unite with water to form acids.

9. *Symptoms of poisoning by digitalis:* "Nausea, and occasionally vomiting. Sometimes colic and diarrhea. After two or three hours, marked diminution in the frequency of the pulse, which may fall to 40 or even 25. Dyspnea, attended by a sense of oppression in the chest and coldness of the extremities. Headache, vertigo, and tendency to sleep. Usually attacks of syncope occur, provoked sometimes by the slightest movement of the patient. Death is generally by syncope, sometimes after several hours of coma succeeded by convulsions. *Treatment:* The patient must be kept strictly in the recumbent position. The stomach should be washed out with infusion of tea by the stomach tube. Stimulants should be given."—(Witthaus' *Essentials of Chemistry.*)

10. *Apomorphine* is morphine minus water. It is produced by heating morphine with hydrochloric acid to 150° C., under pressure.

BACTERIOLOGY.

1. To *prove that bacteria cause disease* it is essential: (1) That the microorganism be found in the tissues, blood, or secretions of a person or animal sick or dead of the disease; (2) the microorganism must be isolated and cultivated from these same sources; it must also be

grown for several generations in artificial culture media; (3) the pure cultures, when thus obtained, must, on inoculation into a healthy and susceptible animal, produce the diseases in question, and (4) the same microorganisms must again be found in the tissues, blood, or secretions of the inoculated animal. These are called the rules or postulates of Koch.

2. *Effect of temperature upon bacteria:* As a rule bacteria will rarely grow below 16° C. and above 40° C. A few will grow at a temperature between 60° and 70° C. and are called thermophilic. Most bacteria are killed by temperatures above 60° to 75° C., but their spores can resist boiling water for some minutes, though killed by dry heat if exposed to 150° C. for an hour or to 175° C. for ten minutes. Cold inhibits the growth of, but does not destroy, bacteria; immersion in freezing mixtures kills many bacteria; but some bacteria and spores are capable of resisting intense cold. Bacteria usually grow best at room temperature; many of the pathogenic bacteria grow best at body temperature and some at a temperature a little above that of the body.

3. *How* antitoxin produces immunity and effects cure is not known, but *theories* deduced from observed facts are as follows: "As the various pathogenic bacteria produce the causative toxins of their respective diseases, so the organic cells of the body, reacting under the stimulus of the poisons thus introduced, immediately proceed to elaborate defensive bodies, which if produced in sufficient quantity will neutralize the effects of the toxins. Residual antibodies remaining in the blood after recovery render the animal immune for a time against the disease. The immunizing and curative effects obtained by the injection of the blood serum of an immunized animal into the circulation of another animal are due either to direct chemical neutralization of the toxins themselves by the antibodies so introduced (Behring, Kitasato), or to a particular influence exerted by the antibodies upon the living cells of the organism which, being affected in two opposite directions, remain neutral to the disease (Buchner). Some authorities hold that these results are due to the conjoint action of leucytic and chemical forces. Ehrlich's sidechain theory assumes that every toxin contains toxophore molecules having direct toxic action, and haptophore molecules which combine the toxophores with a similar combining group of molecules in the tissue cell of the attacked organism. The tissue cell molecules being destroyed by the toxophores, a rapid and profuse regeneration of similar molecules occurs in side chains, and these molecules overgrowing are carried into the circulation, becoming the antitoxin, which acts by combining with the haptophores of newly-arrived toxin, using up their combining power before they can reach the tissue cells."—(Potter's *Materia Medica*, etc.)

4. The *bacterial findings in puerperal septicemia* include the *Streptococcus pyogenes, Staphylococcus pyogenes, gonococcus, Bacillus coli communis, Bacillus diphtheriæ Bacillus ærogenes capsulatus, and Bacillus typhosus.*

5. *The Widal reaction:* "Three drops of blood are taken from the well-washed aseptic finger tip or lobe of the ear, and each lies by itself on a sterile slide, passed through a flame and cooled just before use; this slide may be wrapped in cotton and transported for examination at the laboratory. Here one drop is mixed with a large drop of sterile water, to redissolve it. A drop from the summit of this is then mixed with six drops of fresh broth culture of the bacillus (not over twenty-four hours old) on a sterile slide. From this a small drop of mingled culture and blood is placed in the middle of a sterile cover-glass, and this is inverted over a sterile hollow-ground slide and examined. . . . A positive reaction is obtained when all the bacilli present gather in one or two masses of clumps, and cease their rapid movement inside of twenty minutes."—(From Thayer's *Pathology.*)

6. The *microscopic blood findings in pernicious anemia:* Diminution in the number of red blood corpuscles (this may be excessive, as low as 500,000 per cubic millimeter); the hemoglobin is also diminished, but not so markedly as the number of red cells; normoblasts, megaloblasts, microcytes, and macrocytes may be found; crenation and poikilocytosis may be observed; there is no leucocytosis.

7. To *determine the opsonic power of the blood:* "For this estimation it is necessary first to prepare a quantity of living human leucocytes from some indifferent source (either the patient or some normal individual), from which the plasma has been completely removed. This is done by receiving the blood, as it exudes from a needle puncture, into a weak solution of sodium citrate, centrifugalizing the mixture thoroughly, pipetting off the citrated plasma, adding normal saline solution to the deposited mass of red cells and leucocytes, mixing thoroughly and again centrifugalizing. A repetition of this "washing" with normal saline and the subsequent removal of the supernatant fluid leaves a sufficient quantity of leucocytes and cells entirely freed from the fluid (which possibly contained excess of opsonin) in which they were originally suspended. Next a small quantity of blood to be tested is collected in a small pipette and allowed to clot, and the serum is separated. Similarly the serum from the normal individual or "control" is prepared. Finally a homogeneous suspension of the test-bacterium is prepared by emulsifying some of the bacterial growth in distilled water and carefully centrifugalizing, in order to throw down any possible clumps or masses of microorganisms. By means of a suitable measuring pipette, equal quantities of washed cells, of bacterial emulsion and of the patient's serum are taken up and thoroughly mixed, and the mixture incubated at body temperature for fifteen minutes. At the end of this time, after preliminary manipulations to ensure that there is thorough incorporation of the mixture, blood-films are spread there—from on an ordinary glass slide, fixed, and stained. A second mixture, in which the normal serum is substituted for the patient's serum, is prepared in an identical manner. The two slides are examined microscopically, and the number of bacteria taken up and ingested by the first fifty consecutive polymorphonuclear leucocytes encountered in each film is noted. The ratio between the resulting sums is then expressed in the form of a fraction, of which the total contents of the fifty cells mixed with the patient's serum forms the numerator, and that of those with the normal serum the denominator. This fraction is, however, usually expressed as a percentage of unity—which is represented by the normal serum. Thus, supposing 150 bacteria were counted in fifty cells of the preparation made from the patient's serum, and 100 in a similar number in the preparation from the normal control, the index would be represented by $\frac{150}{100}$ or 1.5. If, however, the specimens chosen had given the figures 60 and 90 respectively, the fraction would have been $\frac{60}{90} = 0.66$."—(Bosanquet and Eyre's *Serums, Vaccines and Toxins.*)

8. Three or four bacteria to a leucocyte would be a fair average.

9. To demonstrate the existence of *tubercle bacilli* in the sputum: The sputum must be recent, free from particles of food or other foreign matter; select a cheesy-looking nodule and smear it on a slide, making the smear as thin as possible. Then cover it with some carbolfuchsin, and let it steam over a small flame for about two minutes, care being taken that it does not boil. Wash it thoroughly in water and then decolorize by immersing it in a solution of any dilute mineral acid for about a minute. Then make a contrast stain with solution of Loeffler's methylene blue for about a minute; wash it again and examine with oil immersion lens. The tubercle bacilli will appear as thin red rods, while all other bacteria will appear blue.

10. *Diseased conditions excited by the gonococci:* Gonorrhea, ophthalmia neonatorum, arthritis, tenosynovitis, perichondritis, subcutaneous abscess, intramuscular abscess, salpingitis, pelvic peritonitis, adenitis, pleuritis, endocarditis, septicemia, acute cystitis, chronic cystitis, pyonephrosis, and diffuse peritonitis.—(From McFarland's *Bacteriology.*)

(*To be continued.*)

Infection of Middle Ear with Vincent's Organisms.—J. Adam reports four cases of this condition, three of which came under his observation during a period of six months. He believes that this type of infection is more common than has been supposed. The condition for which one is apt to mistake it is diphtheria. The disease is chronic marked by the presence of a foul-smelling and profuse discharge, masses of profuse and readily bleeding granulations in the more pronounced cases, erosion of the external parts of the ear, slight tendency to the formation of membrane, and slight glandular involvement. There is not much disturbance of the general health and there is no pyrexia. —*British Journal of Children's Diseases.*

RECENT ADVANCES IN DERMATOLOGY AND SYPHILOGRAPHY.

BY CHARLES MALLORY WILLIAMS, A.B., PH.B., M.D.,

NEW YORK.

PROFESSOR OF DERMATOLOGY, UNIVERSITY OF VERMONT.

SOME of the best of the recent work in dermatology has been devoted to the study of psoriasis, but so far with very meager results. Schamberg[28, 29] has recently published a number of very interesting articles upon this disease, examining particularly the evidence in favor of its bacterial origin. He found no organism constantly present, but a considerable number present now in one case and now in another. Preparing antigens from psoriatic scales, and from cultures of the various organisms found, he attempted complement fixation with the serum of psoriatic patients, and failed in all cases. He examined also the bactericidal power of chrysarobin, pyrogallic acid, and arsenic—drugs of known value in psoriasis—and found it very slight, while calomel in suspension showed decided germicidal qualities, but was without effect on psoriasis. As far as these experiments go, they are in opposition to the theory of the parasitic origin of the disease. Another part of his work, however, shows more positive results. A number of patients with well developed psoriasis were kept in private rooms at the Polyclinic Hospital, where all their food was carefully analyzed and measured, and analyses made also of the daily discharge of feces and urine, and of the scales produced by the eruption. He concludes that these patients store nitrogen with extraordinary ease—that even on a very low protein diet, the discharge of nitrogen is less than the intake, and that a very low protein diet has a distinct and remarkably beneficial effect on the course of the disease. The patients were given no local treatment whatever, but improved wonderfully, the eruption almost disappearing when the diet was made sufficiently poor in nitrogen. In some of them a high nitrogen diet was given for a short period, to try the effect, and the eruption regularly grew worse. To get good results the diet must be *very* poor in nitrogen—about 4-5 g. a day—and must be followed for several weeks. After improvement was well established he found it possible to increase the amount of nitrogen without causing a relapse. The diet called for by this treatment is hardly sufficient for a man at hard work—even the patients living quietly in hospital were often hungry, but were willing to stand the discomfort because of the very evident improvement. In ordinary practice it would be difficult to maintain so strict a regimen, but it is possible to approach it, at least, and the results are good. Indeed, Schamberg was able to do this with some of his dispensary cases, and Bulkley's boiled rice diet is but a variant of the same method. Of course, this treatment does not prevent relapses, and it tells us little of the true nature of the disease, but it is often very useful in practice. Its effects are most evident in the worst cases, where large areas of skin are involved; while in the mild types with only a few scattered lesions, the improvement to be expected is but slight.

The most recent proposal for the treatment of psoriasis is the injection of autogenous serum. Gottheil[15], Hilario[17], and Howard Fox[14], in this country, have each reported series of cases, and claim very good results. The technique is very simple. Under antiseptic precautions, 40 to 200 c.c. of blood is drawn from a vein in the arm into a sterile container, and allowed to clot. The serum is then separated, either by allowing the blood to stand, or by centrifuging, and the clear serum is injected into a vein. Usually, the operator injects all the serum he recovers, but some observers state that the results are as good with small amounts as with large. With a high speed electric centrifuge, the whole operation can be finished in an hour. If more convenient, the clotted blood may be kept in an ice box, and the serum injected 24 or 48 hours after it is drawn. The whole operation must be conducted under the strictest antiseptic precautions, but a strong reddish color in the serum, due to a few red corpuscles, does not unfit it for use. As a rule, six to ten injections are made at weekly intervals. In a few cases, the psoriatic patches disappear under the serum treatment alone, but generally they do not do so: the advantage claimed for the treatment is that after its use patches will yield to a 2 per cent. chrysarobin ointment, which previously had been rebellious to all treatment, even the most energetic. The method is still on trial, and it is by no means certain that it will do more than can be accomplished by careful diet with vigorous application of strong ointment. As pointed out by Wise[33], the vigor of the rubbing seems to be an essential feature of the local treatment of psoriasis, and the physician should see that it is thoroughly carried out. The rationale of the serum treatment is still an entire mystery. The only change in the blood, as far as known, is the removal of the corpuscles and the fibrinogen, and at present there is no known explanation of how this affects the skin, or other organs. There seems to be some change, by virtue of which the reaction of the skin to certain drugs and other substances is altered; more than that we cannot say. The most probable field of usefulness lies among those cases which are very extensive, and resistent to all other methods.

The treatment with autogenous serum has been used in other diseases also, and with very encouraging results. The cases selected have been, as a rule, those in which itching is a marked feature; cases in which the skin seems to be abnormally irritable; such as general pruritus, chronic eczema, urticaria,

and prurigo. Another class that is often improved is the pemphigus group, including dermatitis, herpetiformis. One of the most recent articles is by the late Arthur Swann[42], recording the successful treatment of a case of chronic and very rebellious urticaria with serum from the patient's brother. Spiethoff[43] who has done a great deal of work in this line, claims that the results with the patient's own serum are as good as those with the serum of another, and of course the use of autoserum avoids the risk of conveying disease. Bruck[5] claims equally good results from the injection of normal salt solution, but later reports are contradictory.

Tinea cruris, or eczema marginatum, has received attention lately, and the disease is probably much more common than is generally supposed. It involves usually the region of the crotch, and may appear also in the axillæ, between the toes, and rarely between the fingers. It is very probable that many cases formerly called eczema of the toes, and which proved very resistant to treatment, were really caused by this epidermophyton inguinale. The organism, unlike most of the tineas, does not attack the hair, but thrives in the deeper layers of the epidermis. Warmth and moisture seem to favor its growth. The recognition of the micelia and spores with the microscope is usually easy, but may be very difficult. Treatment is very satisfactory, but as the organism is usually deep in the epidermis, and as it leads to a proliferation of horny cells which protect it from external applications, treatment must be very thorough, and tincture of iodine may be inefficient. A very good preparation recommended by Hartzell[18] is an ointment containing 3 per cent. of salicylic acid and 5 per cent. of benzoic acid, to be rubbed in thoroughly. Montgomery[26] recommends thorough softening and removal of the superficial epidermis, and then rubbing with an ointment containing 5 per cent. of chrysarobin in lanolin and vaseline.

The treatment of various dermatoses by vaccines is still a subject for discussion, and reports are very variable. Naturally, the favorable results get into print; the failures go unrecorded. In acne, the vaccines seem to be beneficial in some cases, especially those in which there is deep suppuration, but, nevertheless, they should not be relied upon to the exclusion of other measures. Nothing can take the place of careful local treatment—removing comedoes as they appear, opening pustules, keeping the scalp clear of infection. In furunculosis the results are often excellent, but the dosage must be carefully watched, as too large or too frequent doses are apt to make the disease worse. All forms of cutaneous tuberculosis are improved by tuberculin, the dosage being so regulated as never to produce a reaction, and the cases carefully selected, since a complicating pulmonary tuberculosis with fever is usually aggravated by this treatment. Towle[44] has devised a new method of vaccine therapy, applying the material in ointment form, and claims results as good as those obtained by injection, but his work needs confirmation.

But after all, the most important advances have been in the study of syphilis, advances so great that our whole conception of the disease has been revolutionized in the past ten years. The *Spirochæta pallida* of Schaudinn and Hoffman has been definitely established as the causative organism, but of its life history we have learned almost nothing. A number of papers have been published, describing complete life cycles, resting stages, etc., but until these have been confirmed by other observers judgment must be suspended. Noguchi[29] was the first to succeed in cultivating the spirochæta in vitro. He found it difficult to get his first generation to grow in artificial media, but once it was started, transplants were fairly easy to get, and spirochætæ grown under these conditions proved pathogenic to rabbits. He has thus fulfilled all the conditions required to prove the pathogenicity of the organism, and his work has been confirmed by others. In none of his cultures did he observe any material alteration of the organism. Important as this work is, it would lose half its value, without the discovery that the rabbit, one of the commonest of laboratory animals, is susceptible to syphilis, and gives the investigator the opportunity to obtain pure cultures in vivo, and to test the infectiousness of various tissues. Monkeys have been used in this work ever since the epoch making experiments of Metchnikoff[24] and Roux, but they are expensive and difficult to handle, and progress was therefore slow. Bertarelli[3], however, succeeded in inoculating the anterior chamber of rabbits' eyes, carrying the strain through a series of rabbits, and then inoculating an ape from the last of the series. Later[45], it was found that the testicle of the rabbit was an even better culture medium, and they could be inoculated also on the eyelid, and by intravenous injection, the organism being recovered in all cases. After inoculation there is a period of incubation, corresponding roughly to that in man, in which no lesions are observed. Then an infiltration appears in the infected part, and later secondary lesions may appear, resembling the papular syphilide. The disease is usually self-limited—at least the lesions disappear spontaneously, although this disappearance is more rapid under the influence of salvarsan. After the lesions have disappeared, relapses may occur. It is interesting to note that at least one case has been observed[16] in which a male rabbit, inoculated in the testicle with blood from a patient with paresis, developed an ulcer on the prepuce, and infected two females in mating, the spirochætæ being found in all the lesions.

Our conception of the course of the disease has been clarified in several ways. In the first place, we now know that the poison is spread throughout the system long before the appearance of the secondary eruption, even before the appearance of the chancre as is shown by the appearance of a positive Wassermann reaction, in some cases, on the day the primary lesion was first observed, and in the majority of cases by the end of the third week. Hartwell[17] inoculated rabbits with defibrinated blood from seven patients with primary syphilis, and obtained positive results in three. As further evidence of this rapid distribution of the poison, Audry[1] and Lavan report a case in the fourth week after the appearance of a lesion on the penis, in which the blood showed a positive Wassermann reaction, the spinal fluid was under increased tension, and contained an increased number of cells, and the administration of salvarsan was followed by meningeal symptoms lasting a week, but which did not recur under further treatment. Wile[51] and Stokes made careful neurological and serological studies of six cases of primary syphilis, from one to six weeks after the appearance of the chancre and before any eruption had developed. General adenopathy was discoverable in only two of the six cases. The Wassermann re-

action in the blood was positive in five—and by accident not performed in the sixth—and all six showed some involvement of the nervous system. The headaches which often mark the onset of the secondary period are undoubtedly due to the presence of spirochætæ in the central nervous system; and I have myself observed in the past year at least four cases in which disturbed hearing was a prominent symptom at this time. Beck[7] reports that in 80 per cent. of cases of secondary syphilis examined by him, in which no salvarsan had been given, and in spite of normal hearing, there was a distinct shortening of the period of bone conduction.

It has always been recognized that the poison is distributed throughout the system in the secondary period, but we are only beginning to realize the frequency with which vital organs are attacked. Warthin[47] reports finding the spirochæta in all of fifty hearts from patients with hereditary syphilis, and in the hearts of about half of a series of one hundred and fifty patients in whom there was a suspicion of acquired syphilis. He believes the localization in the heart to be more frequent than that in the liver, and he found the spirochætæ in hearts in great numbers when they were not to be found elsewhere in the body.

Of equal importance with this wide and rapid distribution of the spirochæta is its persistence. There are authentic records[62] of the transmission of syphilis twenty years and more after infection, the spirochæta has been found in the brain of paretics, in the spinal cord of tabetics, and in the hearts of old syphilitics many years after infection, and inoculations with blood and with tissue at a very late period have been successful. Graves[16] succeeded in inoculating one rabbit with the blood of a taboparetic who had been infected eighteen years before, and another with blood from a paretic infected fourteen years before. Levaditi[23] also inoculated a rabbit with the blood of a paretic who had been infected fifteen years before. Noguchi[30] inoculated rabbits with an emulsion of the brain of patients recently dead of paresis. In view of these facts we must revise our views of the duration of the period during which the disease may cause clinical symptoms, and during which there is danger, even though slight, of its spread to others. The possibility of transmission ends only with the death of the last spirochæta; until that happens the disease may at any time enter upon a new period of activity, and a fresh lesion may develop upon a mucous or a cutaneous surface, whence the organism may be carried to a new host.

It is now possible to make a positive diagnosis of syphilis from the first appearance of the chancre by the detection of spirochætæ in fluid obtained from it. The simplest and quickest method is by examination of the fresh specimen with dark field illumination, and in ordinary cases the diagnosis can be made in a few minutes. The enormous importance of this lies in the fact that it enables us to begin treatment at once.

The Wassermann reaction is still the most useful laboratory test at our disposal for constitutional syphilis. It may appear as soon as the chancre, but in the majority of cases not till the third or fourth week, and in a few it does not become positive till much later. It is not certain how long it may remain, but apparently for life, in some cases. It is important to notice, however, that it varies from time to time, even in untreated cases[7], an occasional negative reaction appearing between positive ones. After the ingestion of alcohol—about 1½ pint of beer or 6 oz. of whiskey—the reaction is regularly negative for from one to three days[10]. It is also important to remember that about 5 per cent. of cases having active secondary symptoms give a negative reaction, even if the test be repeated. A single negative reaction, therefore, has very little diagnostic value.

It is commonly stated that an interval of two weeks should be allowed to elapse after stopping mercurial treatment, before taking blood for the test. As far as I have learned, there is no experimental proof of this requirement. Nelson[27] states that of fifty patients undergoing energetic treatment with mercury for seven weeks, the serum reaction has not changed in a single case. I have had a similar experience myself, with patients receiving an injection of 2 grains of salicylate of mercury once a week for several weeks, and Craig[9] states that even "prolonged treatment with mercurials does not cause the reaction to disappear permanently," and prints statistics to prove it. He adds, to be sure, that "in many cases, if the drug is being taken at the time of the examination, the test will be negative," but he cites no instances to support the statement.

Treatment with salvarsan, even a single dose, will in many cases convert a positive reaction into a negative one, especially if the drug be administered early in the course of the disease, but the change is not immediate, like that observed after the administration of alcohol. It is more gradual, occurring usually about two to four weeks after treatment, and is probably to be explained by the gradual elimination of the substances responsible for it, while no more are produced, as the spirochætæ have been destroyed. It often happens, however, that a reaction which has become negative under treatment will later become positive again, so that a series of negative reactions over a considerable period of time is necessary before it is safe to assume that the disease is extinguished. And even this is not enough. There may be in the body a colony of spirochætæ so inactive, or so shut in, that they give no symptoms, clinical or serological, for the time being. In such cases, a dose of salvarsan will usually be followed within forty-eight hours by a positive Wassermann reaction, though the change may be delayed for a week. This provocative injection of salvarsan is now recognized as essential before any case can be discharged as cured.

In all estimates of the value of the Wassermann reaction, the technique used must be considered. Reports from different laboratories may show marked divergences. Thus Revaut[35] sent the blood of syphilitics to three different laboratories in Paris, and the results were in entire accord in only 61 per cent. of the cases. In 3 per cent. all three reports were different, while in the remaining 36 per cent. one report differed from the other two, usually because one report was doubtful and the other either single plus or negative. About the only conclusion to be drawn from these statistics, however, is that some laboratories use more delicate antigens than others: in the strongly positive cases, as a rule, all agree, and the clinician is coming to lay stress only on the strong reactions, all others being considered more or less doubtful.

The occurrence of positive reactions in other diseases than syphilis has aroused a good deal of dis-

cussion, and the question is not yet settled. Ravaut, in the paper quoted above, found the reaction very variable in non-syphilitic cases, the different laboratories giving different results, and the reaction changing rapidly in the same patient. In fourteen such cases treated with salvarsan, the reaction became positive in five, turning quickly negative again. He cites a case of large and inflamed tonsils in which the report of the reaction was positive from two laboratories, negative from a third, and partially positive from a fourth. Nicolas and Gaté[25] report sixty-three cases, in which very careful examination and anamnesis failed to show any trace of syphilis, yet twenty-four—*i.e.* 39 per cent.—gave a positive reaction. It is to be noted, however, that in fifty-one of these sixty-three cases the reaction was performed twice at intervals of eight to 15 days, and in only three was the reaction positive both times. Craig[5] states that out of 1957 patients diagnosed as suffering from some other disease than syphilis, only eleven, or 0.56 per cent., gave a strongly positive result. Four of these eleven were suffering from malarial fever, and the reaction disappeared with the subsidence of the fever. In three cases the diagnosis was tuberculosis, but all three recovered under specific treatment, and in two of them a history of syphilitic infection was afterward obtained. The reaction is regularly positive in yaws, relapsing fever, leprosy, and the febrile stage of certain malarial infections. It is often positive in acidosis, carcinoma, pemphigus, septic conditions, tuberculosis, trypanosomosiasis, and there are other diseases also which occasionally give slight reactions. It is evident, therefore, that in the diagnosis of syphilis the weak reactions are of little value, and even the strong ones must be interpreted in connection with the history and clinical signs.

As a guide to treatment, a positive diagnosis being once established, the weak reactions are almost as important as the strong ones, and the aim of all therapy is to extinguish all symptoms, serological as well as clinical. As long as the reaction is positive, even to a slight degree, there are presumably living spirochætæ in the body, and there is the possibility that they will multiply and later produce symptoms. The first sign of relapse, in latent syphilis, is usually the development of a positive Wassermann reaction.

Noguchi's[12 21 22 31 42 46] luetin test has not yet come into general use, on account of the great care necessary in preparing the reagent. Now that a preparation is on the market, we may expect a rapid spread in its use. The reagent is a suspension of killed spirochætæ grown on artificial media, and sterile on artificial media, and when inoculated into animals. In performing the test, 0.07 c.c. of the reagent is injected into, not under, the skin. There may be a slight erythema, which soon subsides. In positive cases, a papule appears at the point of injection, usually in 24 to 48 hours, though its appearance may be delayed a few days, and gradually increases in size for four or five days. At the end of that time, the papule may recede, or go on to form a pustule, which soon dries to a crust, and heals, leaving a small scar. It is well to inject a little sterile salt solution at another point, when making the test. It is not uncommon for this control injection also to cause the development of a papule, on account of the susceptibility to trauma of syphilitic skin, but the reaction is seldom as intense or as lasting as that caused by luetin. Practically all observers agree that the test is negative in primary and in untreated secondary cases, and unreliable throughout the early stages of the disease. In the later stages, however, the majority of cases react, and the test is then probably at least as delicate as the Wassermann, some cases with a negative Wassermann giving a positive luetin, and vice versa. There are not yet enough statistics to give percentages. Certain European observers have reported positive results in non-syphilitic cases, but others, and practically all American observers, believe that the test is absolutely specific. It is a valuable addition to our means of diagnosis, especially as it is most serviceable at a time when the Wassermann reaction often fails.

The best method for treating syphilis is still unsettled, but certain ideas are gradually coming into general acceptance. In the first place, all authorities agree that treatment must be started at the earliest possible moment. If treatment is begun wihin a week or two of the appearance of the chancre, and is thoroughly carried out, we may reasonably expect a cure in from 80 to 90 per cent. of the cases, whereas later in the disease a radical cure is difficult, and often impossible, to obtain. The standard of cure adopted by the United States Army is rigorous, but nothing less is satisfactory, and it is probably sufficient. It is as follows[33]: "One year without treatment, without any suspicious clinical signs, with several negative Wassermann reactions and no positive ones, and with a negative provocative Wassermann reaction and luetin test at the end of the year." "An examination of the spinal fluid should also be made, if possible." To attain this, vigorous treatment is necessary. It is best to begin with mercury, preferably an injection, or if this is not available, with a week of inunctions, and then to give salvarsan or neosalvarsan, beginning with a small dose. If mercury is given first, the resistance of the body is increased, and a certain number of spirochætæ are destroyed, so that the first dose of salvarsan is seldom followed by a reaction. The use of salvarsan should then be continued for four to six weeks, and mercury should be administered, either between the doses of salvarsan, or for six weeks following it. So far all authorities agree. Up to the present time, the habit has been to give the salvarsan once a week, but the tendency is growing to give smaller doses twice or thrice a week, and this probably is the better way, as the drug is eliminated rapidly, and very little is left in the system after 48 hours. Scholtz[40] gives salvarsan twice a day for two days—agout 1.0 g. in all—and then mercury for four or five weeks. He claims 90 to 100 per cent. cures in primary syphilis, and 80 to 90 per cent. cures in early secondary cases. After an initial course like that outlined above, the use of the active drugs is suspended for a month or six weeks, during which time iodide of potassium, or sulphur, or both may be used. A Wassermann reaction is then taken and the treatment repeated, to the full extent if the result is positive, but shortened if the result is negative. After another six weeks interval the Wassermann reaction is again taken, and if it be positive, the whole course must be repeated. If, on the other hand, the Wassermann reaction has been negative ever since the first course, the chances are that a radical cure has been obtained. Nevertheless, it is safer to give another short course. In the secondary period the chances of a radical cure are not so good, but the attempt should be made.

In latent and in tertiary syphilis the problem is more difficult, and there is no general agreement as to what had best be done. Vigorous treatment will remove all cutaneous lesions, and will relieve many symptoms of visceral involvement, if such exist, but in a large proportion of cases the Wassermann reaction remains positive in spite of all that we can do. Of course, such cases should remain under treatment, but there is no agreement as to how intense this should be, or how much salvarsan should be used.

Since tabes and paresis have been shown to be true syphilitic diseases, there has been a notable increase in the efforts to cure them. Treatment administered in the ordinary way was shown to be inefficient, or to produce, at most, merely temporary improvement. It seems as if the spirochaetae in the central nervous system, particularly when growing in the nerve tissue itself, were almost beyond the reach of drugs circulating in the blood. For this reason, attempts were made to reach them by direct injection of neosalvarsan into the spinal canal,[34, 45, 49, 50] but the doses used were too large, and were, in many cases, very irritating. Then Swift[44] and Ellis advised their method of using salvarsanized serum. The patient first receives intravenously a full dose of salvarsan, and an hour later, 50 to 60 c.c. of blood is drawn, and the serum separated by clotting, or centrifuging, or both. The clear serum so obtained is heated at 56°C. for half an hour, cooled, and then injected at body temperature, either pure, or diluted with salt solution. The dose of serum is 10 to 20 c.c. After injection, the foot of the bed is kept elevated. The injection is often followed by a temporary increase in the severity of the symptoms, after which there is usually some improvement. From eight to ten such treatments are given at intervals of two weeks. In order to be able to give an exact amount of salvarsan, Ogilvy[32] modified this technique by first drawing and centrifuging blood and adding to the serum a definite amount of salvarsan in solution—usually 0.25 to 0.5 mg., heating at 37°C. for 45 minutes, then at 56°C. for 30 minutes, cooling and injecting at once. He claims that the method is more efficient than that of Swift and Ellis, and equally well borne. Other workers have returned to the direct injection of neosalvarsan, using very small doses, and report good results. It is quite too early to decide which method is best. By any of them it is possible to bring about considerable improvement in most cases of tabes and in some cases of early paresis, and to check the disease in some few instances. The effects in paresis are in general not so good as those in tabes, and of course there is no chance, in either, of restoring any nervous tissue that has once been destroyed. Curiously enough, reports are now being published[15, 20, 36, 37] of equally good results from the use of salvarsan by the intravenous method only, given in small and repeated doses, and in conjunction with mercury, so that it is by no means certain that the intraspinous method will maintain itself. The most important thing in the treatment of nervous, as of all forms of syphilis, is to begin early, and to keep it up. Byrnes[6] of Johns Hopkins reports the administration intraspinously of blood serum containing 1/50 to 1/25 of a grain of $HgCl_2$ in solution; and claims marked improvement in cases of tabes, better than that obtained with salvarsanized serum, and with less reaction.

Since the introduction of the Wassermann test, the evidence has become almost overwhelming, that the mother of a syphilitic infant is herself always syphilitic. The cases in which the mother shows a negative reaction, and no signs or history of the disease, past or present, are so few that they may be safely ascribed to errors of observation. Colles' law is explained: the mother cannot acquire syphilis, because she already has it. There is still some discussion about the possibility of a purely paternal origin of congenital syphilis, but the weight of opinion is increasingly against that supposition, which was required only to explain those cases in which the mother seemed to remain healthy; if she is really infected, why assume a roundabout course through the fetus? The absence of a chancre proves nothing, as it is found in only about 37 per cent of recently infected women, in any case. It is hardly conceivable that an ovum infected at the time of impregnation should ever develop, and we now know that the spirochæta will not live on egg albumen alone, but requires differentiated cells, which are not present in the ovum. Boardman[4] has published a very good summary of the whole subject of congenital syphilis. On the basis of his own observations, as well as a careful study of the literature, he concludes that abortion in the first three months is very rarely due to syphilis; and that miscarriages from the fourth to seventh month are rarely due to syphilis; if the fetus is born alive. On the other hand, syphilis is a frequent cause of miscarriage, when the fetus is dead, and a very frequent cause of premature birth. It is highly probable, therefore, that the infection of the fetus occurs in the later months of pregnancy.

There have always been exceptions to Profeta's law, that the child of a syphilitic mother, though apparently healthy, is immune to the disease. *A priori*, there is no reason to suppose that a woman in whom the disease is latent must necessarily infect her offspring, though she does so in at least 80 per cent. of the cases and probably in nearly all. In fresh, untreated cases, the infection of the fetus is practically invariable. This is true also of cases in which the mother receives her infection during the first five months of pregnancy; while if the mother is infected after the sixth month, the fetus usually escapes contamination. It is probably this last group of cases which has furnished the greatest number of exceptions to Profeta's law.

The most important part of the treatment of congenital syphilis is the treatment of the mother, especially during her pregnancy. Mercurial treatment before pregnancy is of little use in saving the child, while active treatment with this drug before and during pregnancy will secure a very high percentage of healthy children[25]. The treatment with salvarsan and mercury gives even better results, but it must be begun early, and must be energetic. If the fetus is already infected, it is doubtful if treatment of the mother will be of much benefit.

All children born of syphilitic parents should be regarded with suspicion, and should be treated energetically with salvarsan and mercury. Many who are apparently healthy at birth give a positive Warsermann reaction, and others develop a positive Wassermann and other symptoms after a few weeks, and these get the best chance of life if treatment is begun at once.

The recent improvements in the methods of recognizing syphilis, both in life and post mortem, have given us an entirely new conception of the frequency of its occurrence, of the multiplicity of its

lesions, and of the difficulty of eradicating it. At the same time, we should beware of taking too pessimistic a view of the situation. Many a man, in the past, has lived out his life with no reminder of the plague that once afflicted him, and our methods of combating the disease are now better than ever they were before. If we are perhaps less confident of obtaining a radical cure in old cases, we can promise them at least a better chance than they used to have, and in recent infections the chances of eradicating the disease are enormously multiplied.

THE EFFECTS OF RADIOACTIVITY UPON NASOPHARYNGEAL FIBROMA.*

BY D. BRYSON DELAVAN, M.D.,

NEW YORK.

AT the end of more than a decade since my last articles upon the treatment of nasopharyngeal fibroma, I again wish to direct attention to this subject. It has seemed well to review it from time to time, in the hope that the value of improved methods might be studied and their superiority, if any, clearly stated. The spark drawn from the clouds by the kite of Franklin could not have conveyed even to his fertile imagination an appreciation of the pos-

*Read before the Thirty-seventh Annual Congress of the American Laryngological Association, Niagara Falls, June 1, 1915.

sibilities of applied electricity, since the full import and value of any great scientific discovery is something which cannot be at once realized. Year by year in medicine old methods are supplanted, not alone by new and original ones adapted especially to the particular object in hand, but often by the application to them of principles already understood and utilized in other directions. This has been particularly true in the department of radiology, which, has been already tested in many ways, and is constantly finding new fields in which to exercise its usefulness.

The value of radiology in the treatment of fibroma in various parts of the body, especially the uterus, has already been somewhat extensively exploited. Of its application in the treatment of fibroma of the nasopharynx, however, nothing, so far as I am aware, has up to this date been said. It has seemed desirable, therefore, to bring this subject to notice in the hope that the method may be given fair consideration and trial. Its success would mean the ending of a dark chapter of surgery.

By nasopharyngeal fibroma is meant that rare form of growth which, composed mainly of connective tissue and highly vascular, usually takes its origin from the basilar process of the occipital bone, extending downward into the retronasal space, occluding the natural passages, creating pressure upon the parts in its vicinity, and in many cases giving rise to more or less frequent and abundant hemorrhages. The period of the greatest activity of its development is about the time of adolescence. Following this, the tendency to its enlargement diminishes and, in fortunate cases, if enough time be allowed and the conditions due to the presence of the tumor be not too urgent, it may gradually disappear. Such a result, however, is unusual. In nearly every instance the conditions arising from the presence of the growth are so serious as urgently to demand relief. This has been recognized for many generations, and a great number of methods of treatment for it have been devised.

Heretofore, three varieties of treatment have been presented: (1) Removal of the growth after preliminary operation done for the removal of obstructing parts. (2) Removal through the natural passages by avulsion or with the cold snare, and (3) The reduction of the size and of the vascularity of the tumor by electrolysis or by the injection of various chemicals, followed by the removal of the mass thus reduced by means of the galvanocaustic loop.

Of these methods, the first is illogical, unsurgical and, as statistics abundantly prove, deadly. Shock from the preliminary operation is severe; nemorrhage profuse, and recurrence common. In spite of this, it gained the support of the most eminent surgeons of almost two centuries, and even to-day still has its adherents. The second method is a vast improvement upon the first, but is nevertheless liable to provoke serious hemorrhage and shock and to be followed by recurrence of the growth. The third procedure is by far the best, as it is followed neither by shock, hemorrhage, nor the deformity resulting from the extensive removal of important parts. On the other hand, however, the application of the electrolytic needles is a tedious process and sometimes is attended with considerable pain.

While the application of the needles and the manipulation of the galvanocaustic écraseur require much experience and skill, nevertheless a statistical comparison of the three divisions of treatment above referred to leaves no doubt as to which is to be preferred. Thus, of 27 cases removed after severe preliminary operation in which the end results were stated, 59.25 per cent. were cured and 25.9 per cent. died. Of 41 cases removed through the natural passages by avulsion or the cold snare, 95 per cent. were cured, 5 per cent. died. Of 66 cases treated through the natural passages by electrical methods, 100 per cent. were cured.

For several years past much attention has been given to the treatment of uterine and other tumors of the order of the fibromata or myxomata by means of the *x*-ray and of radium. Many cases have been experimented upon, and a sufficient number have been recorded to make it possible to begin to draw conclusions as to definite results. Both in the United States and in Europe the method has gained strong advocates, and if in some instances the enthusiasm of these may seem unduly sanguine, even the most conservative must admit that the success attained renders the method at least worthy of the respectful consideration of the gynecologist; while the similarity of type between the uterine and the pharyngeal growth at once challenges the interest of the laryngologist in the new method of treatment.

Thus, among its advocates in this country may be mentioned Abbe,[2] Kelly,[3] Tousey, Frank and Stern, and in Europe, Krönig, Gauss, Bumm, Wernekro, and Doderlein, all of whom report favorably upon it and recommend it. Pfahler[5] reports of 20 cases, 16 cured or 80 per cent.; Kohler[6] reports of 80 cases, tumor reduced in size, 30 per cent.; Mohr[7] collected 669 cases, cured 56.2 per cent., improved 17.9 per cent., cured and improved (no details) 13 per cent., and not cured 11 per cent. In Mohr's collection of cases the tumor actually disappeared in only 5.3 per cent. These were mainly cases of uterine fibromata, presumably of considerable size and somewhat remotely situated. Fibromata of the nasopharyngeal region are, however, relatively very much smaller and much more directly accessible.

The success of the radium treatment in nasopharyngeal fibroma would not necessarily depend upon the absolute disappearance of the growth. It is a well recognized fact that nasopharyngeal fibroma, unlike other new growths, manifests its greatest activity during the years of adolescence and early youth. Toward the approach of the eighteenth year the tendency to its development steadily decreases. During this period the growth may diminish spontaneously and finally disappear. If, therefore, the size of the tumor can be controlled during the earlier years and until the period of its activity has been passed, nature herself will often intervene and by her own processes render artificial interference unnecessary.

The most hopeful cases seem to be those of slow development occurring in older rather than in younger patients. But even in the case of rapidly growing tumors in patients far removed from the period of retrogression, the success attained by the use of radium in other types of fibroma would hold out strong hope for its usefulness in these. There is reason for believing, moreover, that the effect of the radium upon the growths is active and profound, and that more may reasonably be expected from its use than a moderate reduction in their size.

To Dr. Robert Abbe of New York belongs the

credit of being the pioneer in the use of radium in the United States. For its application to various organs of the body he has originated many ingenious devices, none more so than the one intended for use in the nasal and nasopharyngeal regions. A description of this will be found interesting. In the application of the radium, two objects are to be gained: First, the parts to be treated must be exposed to the rays, and, second, the healthy surrounding structures must be protected from them. It is not necessary that the radium should be introduced actually into the substance of the tumor. All that is required is the exposure to the rays of the surface of the growth, since the blood vessels of the tumor are more abundant near to its surface, and the rays penetrate at least a quarter of an inch, so that the treatment is entirely effective in accomplishing the desired result of profoundly affecting the circulation and thus causing by degrees the reduction of the size of the growth. In order to carry the radium to the desired part, Dr. Abbe uses the following simple methods:

A tube of celluloid, about 3/16 of an inch in diameter and with one end closed like the end of an ordinary test-tube, is cut to the proper length. In the bottom of the section of tube is put the radium. Upon it is packed a bit of cotton or gauze, to keep it in place. The end of a handle made of stout wire is thrust into the tube, and the tube is secured to the handle by a wrapping of adhesive plaster. For the protection of the normal parts, a piece of thin sheet lead, of proper size and shape, is adjusted to the outside of the tube and retained in place by a sufficient wrapping of India rubber gauze, the side covered by the lead being directed away from the tumor.

In using this device one of the nasal cavities of the patient is first locally anesthetized and the radium carrier, properly lubricated, is then passed backward through it until the radium is brought into proper relation with the growth. Proper regulation of the strength of the radium and of the duration of the exposure will prevent injury to the surrounding healthy parts. In a case of Dr. Cornelius Coakley's now under treatment in New York one application of radium has already produced remarkable results.

Should the radium treatment of nasopharyngeal fibroma prove as effective as it promises, and as we already have good reason to hope that it may, we shall be able to congratulate ourselves and the world that the unhappy record of surgical failure made in the past in the treatment of this disease will have been closed.

Incidentally, again, another leaf will have been added to the wreath of fame which so justly covers the brow of Madame Curie.

40 EAST FORTY-FIRST STREET.

THE PRESENT STATUS OF THE DIAGNOSIS OF CANCER OF THE STOMACH.

BY WILLIAM J. MALLORY, A.M., M.D.,

WASHINGTON, D. C.

INSTRUCTOR IN MEDICINE IN THE GEORGE WASHINGTON UNIVERSITY, DEPARTMENT OF MEDICINE, AND ATTENDING PHYSICIAN TO THE OUT-PATIENT DEPARTMENT OF THE UNIVERSITY HOSPITAL.

THE profession should take a less pessimistic view of this subject than it does at present. One eminent physician states that "the search for an early symptom of cancer is nothing more than a beautiful dream";[1] and another writes that "no symptom or symptoms seem sufficient by which to make a diagnosis of cancer."[2]

There are several good reasons why a more optimistic spirit should govern us. It is true that many cases escape recognition till palliative treatment only is possible, but it is equally true that, with the methods of diagnosis in use during the preceding five or ten years, cancer of the gastrointestinal tract from mouth to anus, has been recognized early enough for one-fourth of the cases to be permanently cured, while the number of five-year cures varies from 10 to 50 per cent.[3]

During recent years, the cooperative work of physicians, surgeons, and pathologists has thrown additional light on the early symptomatology of cancer, a number of useful tests have been evolved, which, if not specific are at least of additional aid in the early recognition of cancer, and lastly, surgical procedure has been improved to such an extent that the prospect of the prolongation of life, or even of permanent cure of this disease is better now than ever before. It is therefore reasonable to suppose that a more general familiarity with the early symptoms of gastric cancer, and a more universal, diligent and prompt application of all those tests which have been found to be of diagnostic value, will lead to the recognition of the disease early enough for surgical treatment to be permanently curative in an increasing number of cases.

In the discussion of the early diagnosis of cancer the terms "precancerous disease" and "precancerous stage" are often used. In this connection we should distinguish between the effort to recognize the precancerous *disease* (such as chronic ulcer), which is an easy clinical problem, and the effort to recognize the precancerous *stage* in the ulcer itself which is a problem in pathology.

It is now well recognized that a very large number of chronic ulcers of the stomach develop into cancer. In 79.5 per cent. of cases of cancer examined the pathological evidence was good or fair that ulcer was the first cause.[4] The ulcers which develop into cancer pass through a stage to which the term "precarcinoma" or "precancer" may be applied. This term refers to the microscopic changes in the tissue cells, and their relation to each other, which immediately precedes cancer, and should not be utilized to simply indicate chronic inflammation.[5]

One observer, after studying 684 specimens states that the clinical history, gastric analysis, *x*-ray and serum examinations cannot positively differentiate between chronic gastric ulcer and cancer, especially those without pyloric obstruction.[6] And whenever the clinician feels positive of the clinical diagnosis of chronic gastric ulcer, he should consider that cancer cannot be ruled out by our present methods of clinical investigation. In

the light of such evidence as this no time should be wasted trying to make a refined diagnosis, but the chronic ulcer should be nicely and completely excised. The place for such tissue is in a pathological museum, not in the stomach of our patient.

Graham[2] states that, "In developing histories from those suffering from cancer, we have found them to fall into three classes: first, those in whom the disease seemed to appear suddenly during the enjoyment of perfect health; second, those in whom an attack or attacks in earlier years are definitely stated, and who for years have been well until sudden grave symptoms (as in Class 1) threaten, and third, those who for years have had typical attacks of chronic gastric ulcer.

"In the first and second cases we may find tumor, advanced lesions, and symptoms of previous chronicity suddenly and very acutely developed. We may find those patients whose only complaint is a diffident, weak feeling, and who are chiefly concerned because an epigastric tumor has been discovered. Others complain of languor, weakness, loss of appetite and emaciation, and on physical examination nothing is revealed. The test meal is of value here. We feel sure that, however great the difficulties here met with in reaching a diagnosis, they are less than in Class 3, where ulcer has been present for years. Some patients are weak, emaciated and cachectic when ulcer is the only lesion, but tumors of the stomach are usually cancer (95 per cent.).

"The face of a patient suffering from cancer of the stomach has certain morbid characteristics. Palor is often most noticeable about the eyes, nose and mouth. Wasting, too, shows here, giving a pinched, wrinkled look. The expression is one of stolidity; there is intense conviction of impending danger, and while the patient is intent, as though eager to read your opinion, the expression is not so much pained as hopeless, calm and dejected."[7]

In 85 per cent. of cases the appetite is impaired, and in many instances there is a marked revulsion against meat. Thirst is greatly increased in cases accompanied by obstruction. Pain in cancer is quite a common symptom, though less often noted than in ulcer, but when present it is less acute, more continuous, is described as a dull, strange, depressing ache, and is usually immediately intensified by taking even the simplest food or drink, such as water or milk. Vomiting is often an important symptom, and is of course earlier and more voluminous when the tumor is situated at the pylorus, and causes obstruction. It is usually preceded by pressure, pain, nausea, and salivation, and is followed by temporary alleviation. It often differs from the vomiting of ulcer, occurring immediately after the ingestion of bland fluids.

The above symptoms, or even a few of them should arouse the greatest suspicion, and lead to the application of every test that will yield additional information, for although there is now no specific test, any more than there is a pathognomonic symptom, it is only by a painstaking application of such tests as we have, and a careful evaluation of the information so obtained, together with the clinical symptoms, that we may hope to increase the number of early diagnoses and reduce the present high mortality.

The careful physical examination for the presence of a tumor, although often giving negative results, should never be neglected, for in a few instances of favorable situation for palpation it is an early sign, and since 95 per cent. of tumors of the stomach are cancer, their recognition is of the greatest importance.

The numerous tests which are applied for the recognition of cancer of the stomach fall in two great classes: first, those having as their purpose the demonstration of significant changes in the function of the stomach itself, and second, those for the detection of alterations in the body fluids or secretions. In the latter class belongs the so-called specific or biological test for cancer in general, without reference to the particular organ involved.

The most marked change in the secretory function of the stomach is the deficiency of hydrochloric acid, or the absence of free hydrochloric acid from the gastric juice, as observed by van den Velden as long ago as 1879. While this is a valuable symptom, and was present in 77.5 per cent. of Boas's cases, it is no more characteristic of cancer than hyperacidity is characteristic of ulcer. Free hydrochloric acid or even hyperacidity is more commonly found when the growth involves the pyloric region, and absent when the fundus is involved.

In 125 cases Boas found free hydrochloric acid present 18 times in pylorus carcinoma, and only 4 times in fundus carcinoma. He considers this due to the fact that pyloric cancer usually remains circumscribed longer, while cancer of the fundus spreads more rapidly in all directions and soon produces extensive changes in the secretory glands of the stomach. It should be added that cancer of the pylorus probably is more commonly secondary to ulcer, and an account of its situation produces marked symptoms earlier in its development, than cancer in other situations does. In my judgment, a deficiency in hydrochloric acid, especially if it develops gradually, is of greater diagnostic value than its total absence. For when cancer of the stomach has progressed far enough to produce total absence of hydrochloric acid, there is no difficulty in distinguishing it from other conditions of anacidity, such as true achylia gastrica, neuroses and reflex disturbances such as occur in association with chronic appendicitis and gall-bladder disease.

There is not always a simultaneous loss of gastric ferments. Although this is not of diagnostic value, Glässner has used the fact that both pepsin and rennet are produced in the fundus, and pepsin only in the pyloric part of the stomach, to determine the location of the growth.

The presence of lactic acid in the stomach is a sign of great importance. It occurs, according to the different observers, in from 75 to 95 per cent. of cases. The condition favoring its development are absence of hydrochloric acid and stagnation of food in the stomach. It is therefore found in nonmalignant disease also, but the importance of the presence of lactic acid is further emphasized by the fact that 84 per cent. of gastric diseases accompanied by lactic acid fermentation are cancers. The absence of lactic acid nautrally does not exclude cancer.

The diagnostic value of blood in the gastric contents is very great. It is manifest in from 36 to 40 per cent. of cases, and the presence of occult blood is noted in from 70 to 100 per cent. by different observers, the variability being probably due to the particular method of examination used.

The great importance of occult blood is not limited to its presence in the stomach contents, but is greatly increased by the fact that it is even more frequently found in the feces, and furthermore, to

its *constant* presence in a given case. For while occult blood may appear in the stool in a great variety of diseases, it is apt to be variable; that is, present for a few days and then absent for a few days or longer, while in malignant disease of the stomach the bleeding is apt to be moderate in amount, but when once begun, continuous. This fact is of value in distinguishing cancer from the disease which most closely resembles it, that is, chronic gastric ulcer.

The Solomon test, which consists of an examination for an increased amount of soluble albumin and increased nitrogen in the wash-water after irrigating the empty stomach, has been applied clinically by a large number of observers, and is considered by Boas to be of value in differentiating cancer from chronic gastritis, while simple ulcer and non-ulcerated cancer cannot be distinguished by this method.

The glycyl-tryptophan test of Neubauer and Fischer, is based upon the observation of Abderhalden that cancerous tissue contains a ferment which digests (splits up) protein to a point far beyond the peptone stage. Neubauer and Fischer believed that in the peptid glycyl-tryptophan they had found a substance which was split into glycyl and tryptophan only by the juice of the carcinomatous stomach. If the tryptophan is present in the gastric contents, it is recognized by a rose-red color on the addition of bromine water or bromine vapor. Since serum, blood, pancreatic juice or a large amount of hydrochloric acid interferes with the test and the ferment looked for is present only in ulcerating cancer, its value is limited. Still Smithies[8] reports the test positive in 40 per cent. of 566 cases of cancer of the stomach.

In the Wolf-Junghans test the presence of a relatively large amount of soluble albumin with a low pepsin and hydrochloric acid value, is supposed to be more or less characteristic of cancer of the stomach.[9]

The presence of the Oppler-Boas bacillus is very common in cancer of the stomach, but occurs in non-malignant disease in acid-free stagnating gastric contents. The infusoria, trichomona and megastoma have been noted in malignant disease, and, with other signs and symptoms, are significant but not characteristic.

Fluid removed from the fasting stomach and water used in irrigation should always be examined for pus, blood, and fragments of tissue. The latter may be of great value when examined microscopically.

Schutz[10] considers groups of large round cells with large refractive nuclei very significant, while Simon and Caussad,[11] two French observers, claim that a microscopic examination of the detached cells obtained by irrigating the stomach with normal saline solution gives great aid in diagnosis. Such findings, must, however, assume a position of secondary importance when we recall that it is the relation of the cells to the surrounding tissue which constitutes malignancy, rather than the character of the individual cell.

In the anemia and cachexia of cancer, nothing specific is to be found. The anemia is of the secondary type, but is sometimes so extreme as to resemble pernicious anemia, and may be mistaken for it if a complete examination of the blood is not made.

Schneyer's[12] observation that the digestive leucocytosis is often absent in cancer of the stomach should be noted in studying the blood.

The urine of patients suffering with cancer has been studied in the hope of finding some change which would aid in the recognition of cancer of the internal organs. Ury and Lilienthal[13] found albumose present in two-thirds of cancer cases, and although this varied from time to time in the same patient, the repeated presence of a marked reaction for albumose in the urine should be considered as speaking in favor of the existence of cancer.

The absence of traces of pepsin from the urine was noted by Fuld and Hirayama,[14] but other investigators consider that, at most, the absence of pepsin from the urine is indicative of cancer rather than simple achylia. The increased amount of neutral sulphur found in the urine by Solomon and Saxl[15] was believed to be peculiar to malignant disease of some internal organ, but subsequent wider application of the reaction showed it to be present in other diseases and sometimes absent in cancer.

The so-called hemo-urochrome reaction,[16] obtained by boiling urine with hydrochloric acid and then shaking with ether, was shown by Butterfield[17] to be simply a test for urinary indican, and without diagnostic significance of cancer.

An early attempt was made by Kelling to develop a specific test based upon biological principles. He assumed that cancer cells were foreign or exogenous protein introduced into the system from without. The test as recently applied is based upon hemolysis, and by his improved method he obtained positive results in 90 per cent. of cases examined.[18] His method did not produce uniform results in other hands.

The method of Briger and Trebing,[19] based upon the increased antitryptic action of the blood-serum of cancer patients, seems to have been tried and discarded as inapplicable.

The meiostagmin reaction of Ascoli[20] depends upon a reduction of the surface tension of the diluted serum, which occurs when serum of cancer patients is treated with antigen prepared from malignant tumors. The change is indicated by an increased number of drops in a given quantity of serum, and is measured by an instrument called a stalagmometer. Roosen and Blumenthal[21] report this test positive in 96 per cent. of cases of cancer, but unfortunately, also positive in some other conditions which one might wish to distinguish from cancer, namely, pregnancy and chronic inflammations.

Piorkowski quite recently[22] worked with a polyvalent enzyme emulsion obtained by saponification of cancer tissue from various sources, and found that this precipitated the serum of cancer patients in 99 per cent. of cases.

Of all such serological or biological tests, the one generally known as the abderhalden dyalization method has attracted most attention. It has been applied clinically by a great number of laboratory workers, with varying results, and resulting conflicting reports.

It should be remembered that originally he did not claim the reaction to be specific. It seemed improbable that it would be, but subsequent experiments seemed to indicate that it was, and at that stage he left its further demonstration with pathological cases to clinicians. The question of its specificity is still unsettled, but the fact remains of a positive ferment in the serum, following the parental ingestion of a foreign protein, and the digestion of placental tissue by the serum of pregnant women.[23] The reports by the various workers on its

clinical value are as conflicting as the theoretical discussion, and one receives the impression that, as it has been applied, it is not specific, but like most other laboratory examinations, is of value when taken in conjunction with laboratory and clinical findings.

One unfavorable report noted is from Leitch, of the Cancer Hospital in London.[24] He examined 100 cases, and found of 51 cancer cases, 28 or 55 per cent. positive, and of 49 non-cancer cases, 18 or 37 per cent. positive, and he therefore considers it of no diagnostic value in his experience. Frankel[25] obtained such conflicting results that he considered the method not useful clinically.

On the other hand, Schawlow[26] reported more favorable results. Of 100 cases, making more than a thousand examinations, in 40 cases of cancer of the stomach there was only 7.5 per cent. of failure. He therefore considers that this method gives a higher number of successes than any other at present known, and therefore of great clinical value. Levin[27] applied the method in the study of cases of cancer and tuberculosis, and the analysis of the findings, in his opinion, show that while the test is most frequently positive in cancer, it cannot be considered actually specific.

Blanch Forster,[28] working in the medical clinic of the University of Tubingen, thinks the method clinically appplicable and of value in differential diagnosis. The positive reaction alone, however, is not sufficient to make a diagnosis, but the whole clinical picture must be considered, and the Abderhalden reaction used as one method of examination. Frasiani[29] obtained a positive reaction in 96 per cent. of cancer cases, and negative results in 65 per cent. of non-cancerous cases, and states that the reaction, while not specific, is clinically valuable. Smithies[8] studied 566 cases of cancer in which the diagnosis was confirmed operatively and pathologically, and noted the presence of symptoms and signs in the following percentages:

	Per Cent.
Coffee-ground vomit present	15
Delayed vomiting	40
Glycyl-tryptophan positive	40
Presenting persistent early symptoms of chronic ulcer	41.8
Hemolytic test positive	47
Dyspeptic (chronic ulcer) symptoms	60
Delayed emptying of stomach	66⅔
Abdominal tumor or ridge	75
Occult blood (benzidin or guaiac test)	77
Periodicity	81
Wolf-Junghaus test positive in	86-90
Oppler-Boas bacilli present	83.8

The value of the radiographic examination of the stomach for the diagnosis of cancer is based on the fact that it will reveal the size, shape, position, mobility and peristaltic movements.

Now, while cancer in the course of its development produces changes in one or more of the abovementioned features of the stomach, which may be detected by radiography, the value of this method of examination is limited to a certain extent by the following facts: The above-mentioned facts are not demonstrable until the disease has already involved the stomach to a considerable degree. While the changes produced by cancer have their peculiar characteristics, there are other lesions producing similar changes, sometimes hard to be distinguished. Chronic gastric ulcer is the most common of these, and syphilitic lesion, though rare, cannot be ignored, for it may produce a radiographic picture indistinguishable from that of cancer. In such a case, the Wassermann examination and the result of specific treatment is the specific test.

Despite these facts there are many instances in which the radiographic examination will furnish decisive data, and it should therefore be employed in all suspicious cases.

From this brief review it is apparent that while the early diagnosis of cancer of the stomach offers very great difficulties there have been recent commendable improvements, both in methods and in results. Present facts seem to indicate that immediate increased accuracy in the early recognition of this disease is to be hoped for, not from any single laboratory test or method of clinical examination, but by a more faithful and diligent study of suspicious cases by all methods at our command. While there are many diseases to be considered in the differential diagnosis, the greatest practical difficulty is presented by chronic gastric ulcer. This should not be allowed to pass as "chronic indigestion" and be treated as such indefinitely by medical means, but should be recognized for what it is, and excised in that interesting stage of development when it would furnish material for debate among pathologists, and not be allowed to remain as a menace to the life of the patient and a reproach to the physician.

PROGRESS IN THE USE OF STANDARD SALVARSANIZED SERUM INTRASPINALLY.

A SECOND REPORT ON THE STATUS OF FIFTEEN CASES.

By HANSON S. OGILVIE, M.D.,

NEW YORK,

CHIEF OF CLINIC, THIRD DIVISION, THE NEUROLOGICAL INSTITUTE.

In a former paper* I described a method of preparing *in vitro* a salvarsanized serum of standard strength suitable for administration intraspinally in syphilitic disorders of the central nervous system and reported fifteen cases which had been treated with the preparation. The value of this article was practically limited to the description of the technique elvolved, since at that time the cases had only been under observation for a few months and consequently no attempt was made to draw conclusions regarding the permanency of either the clinical or biological improvements noted. The employment of this serum in a large number of cases over a period of eighteen months has shown that it is a safe and practical procedure when the proper care is exercised in its preparation and administration. Diseases of this kind, however, must be observed over a considerable period before the efficacy of the curative agent, or the manner of its administration, can be established, and I therefore determined to supplement my first, or preliminary, paper with a further report on the status of fifteen cases originally reported. Fortunately I have been able to follow all of these cases clinically, and with the exception of two, I have obtained records of analyses of the blood and cerebrospinal fluid from time to time.

*"The Intraspinal Treatment of Syphilis of the Central Nervous System with Salvarsanized Serum of Standard Strength; Report of Cases." (Amer. Med. Assn., 1914, LXIII, 1936-1941.) Read before the American Association of Immunologists at Atlantic City, June 22, 1914.

The series consisted of seven cases of tabes, six of paresis (two of tabo-paresis), one of cerebrospinal syphilis, and one of syphilitic myelitis. Those cases that still showed serological evidences of the disease when the data for the first paper was collected have been treated consistently, while those that were negative at that time have simply been kept under observation and treated only when there were clinical or laboratory evidences suggestive of a renewed activity of the specific process. The technique as originally described has not been changed in any particular. The strength of the serum employed, and the frequency of administration, have been determined by the character of the case under treatment, the physical condition of the patient, and the degree of resistance offered.

For purposes of comparison the following reports will give the laboratory findings last noted in the article referred to above, as well as these most recently obtained.

Case No. 1. Tabes. Man. Aged 41.		
May 29, 1914	Cerebrospinal Fluid	Blood
	Wass. ++in 1.0 and 0.8 c.c. −below*	−
	Cells None	
	Glob. None	
May 15, 1915		April 21, 1915
	Wass. Negative in all titrations	−
	Cells 2 per cu. mm.	
	Glob. None	

*++=Complete inhibition.
−=Complete hemolysis.

He had four intraspinal treatments between these dates, no salvarsan by vein, no mercury, and no potassium iodide. He has retained all of the clinical improvement noted in June, 1914, and in addition thereto his legs have gained materially in strength. He shows a slight tendency to sway when attempting to turn suddenly, but otherwise his gait and station are only very faintly impaired.

Case II. Tabes. Man. Aged 41.		
June 6, 1914	Cerebrospinal Fluid	Blood
	Wass. ± in 1.0 c.c. −Below	−
	Cells None	
	Glob. ±, 0.2 c.c. (very faint).	
March 11, 1915		Jan. 28, 1915
	Wass. Negative in all titrations.	−
	Cells None	
	Glob. ±, 0.2 c.c. (very faint).	

Between these dates he had three intraspinal treatments. Clinically his condition is markedly improved over what it was in June, 1914. There has been no indication of a return of any of his subjective symptoms. He has gained eight pounds in weight (making a total of eighteen pounds since treatment was first instituted in December, 1913), and can be on his feet the greater part of an entire day without undue fatigue. The improvement in the pupillary light reflex, noted nine months ago, remains as definite as at that time. The deep reflexes and other physical signs are unchanged.

Case III. Tabes. Man. Aged 54.		
May 23, 1914	Cerebrospinal Fluid	Blood
	Wass. ++ in 1.0, 0.8, 0.6, 0.4 c.c. −Below.	Not made
	Cells 4 per cu mm.	
	Glob. +, 0.2 c.c. (slight excess).	
Feb. 9, 1915		
	Wass. Negative in all titrations.	−
	Cells 2 per cu. mm.	
	Glob. ±, 0.2 c.c. (faint excess).	

During this time he had eight intraspinal treatments of 0.25 mg. each, eight treatments of salvarsan by vein, and mercury intramuscularly. The only symptoms that have persisted in this case are the paresthesia and tingling in the lower extremities, and the slight bladder weakness. The latter, however, is much less marked than when treatment was started and on several occasions has disappeared entirely for three to four weeks. There is pronounced improvement in the strength of his legs. He has gained eleven pounds in weight.

Case IV. Tabes. Postman. Aged 23.		
June 9, 1914	Cerebrospinal Fluid	Blood
	Wass. Negative in all titrations.	−
	Cells None	
	Glob. ±, 0.2 c.c. (very faint excess).	
March 11, 1915		Dec. 21, 1914
	Wass. Negative in all titrations.	−
	Cells None.	
	Glob. ±, 0.2 c.c. (very faint excess).	

The patient received one intraspinal treatment when

fluid was withdrawn for the last analysis. He had had no salvarsan by vein and no mercury in any form. After the examination June 1, 1914, and until January, 1915, he gained steadily in walking, but during the past two and a half months he has shown no further improvement. He has never had a return of the tabetic pains however, his bladder gives him practically no trouble and he can walk the length of thirty to forty city blocks with the aid of a light cane. (A note made on his condition in Feb. 1914, before treatment was started, read "He is unable to walk more than twenty feet without assistance.") He has gained six pounds in weight and his general health is good. The improvement in the pupillary light reflex, noted ten months ago, has not been evident for the past four months. At the present time his pupils are about 2 mm. in diameter, round, and fixed to both light and accommodation. The deep reflexes and other physical signs are unchanged.

Case V. Tabes. Man. Aged 50.

		Cerebrospinal Fluid	Blood
May 21, 1914	Wass.	Negative in all titrations.	++
	Cells	5 per cu. mm.	
	Glob.	+, 0.2 c.c.	
April 6, 1915	Wass.	Negative in all titrations.	++
	Cells	None.	
	Glob.	±, 0.2 c.c. (faint excess).	

There was no intraspinal treatment administered between the above dates. He had six intravenous treatments of salvarsan, but was unable to take mercury in any form. The clinical improvement in this case has been more striking than in any of the foregoing, considering the age of the patient and the fact that he was addicted to the excessive use of alcohol for more than twenty years prior to the onset of his trouble. He has been absolutely free from pain during the past nine months and has gained steadily in weight and strength. With the aid of a cane he walks from three to four miles each day that the weather permits. There has been no change in the objective manifestations of the disease.

Case VI. Tabes. Man. Aged 39.

		Cerebrospinal Fluid	Blood
May 9, 1914	Wass.	++ in 1.0 and 0.8 c.c. −Below.	+
	Cells	4 per cu. mm.	(50% inhib.)
	Glob.	Normal content.	
March 27, 1915	Wass.	Negative in all titrations.	+
	Cells	2 per cu. mm.	(50% inhib.)
	Glob.	Normal.	

This case was very resistive to treatment. Between the above dates he had eight intraspinal treatments of 0.25 mg. each, ten intravenous treatments of salvarsan and thirty intramuscular injections of mercury. He had one severe attack of root pain in November, 1914, and two very mild ones during December. For three and a half months he has been entirely free from pain and has gained very markedly in strength. He has not had a return of bladder trouble which was a prominent symptom before treatment was instituted. Objectively there is marked diminution in the extent of sensory disturbances noted at the original examination.

Case VII. Paresis. Man. Aged 46.

		Cerebrospinal Fluid	Blood
June 12, 1914	Wass.	+ (50%) in 1.0 c.c. −Below.	−
	Cells	14 per cu. mm.	
	Glob.	±, 0.2 c.c.	
March 20, 1915	Wass.	Negative in all titrations.	Dec. 1, 1914 −
	Cells	None.	
	Glob.	Normal content.	

This case is perhaps the most interesting of the entire series. When treatment was started in April, 1914, he presented every symptom and sign of an advanced paretic and had been confined to an institution for the insane for more than two years. He reacted badly to both intraspinal and intravenous treatment, and after he had had four of the former and five of the latter it was considered unwise to proceed, owing to his weakened physical condition, and because his mental condition was apparently growing worse. After an interval of two months he was able to resume his treatments and showed signs of marked improvement both physically and mentally. He had nine intraspinal treatments. Eight months ago he was paroled in the custody of his wife and for this length of time it has been practically impossible to detect the slightest evidence of his psychosis. He is bright and alert, has the normal retentive power and shows no trace of the marked speech defect that was strikingly evident at the original examination and during the earlier part of his treatment.

Case VIII. Paresis. Man. Aged 35.

		Cerebrospinal Fluid	Blood
June 2, 1914	Wass.	+ + in 1.0, 0.8 and 0.6 c.c. Below	−
	Cells	None.	
	Glob.	±, 0.2 c.c. (faint excess).	
April 9, 1915	Wass.	Negative in all titrations.	April 16, 1915 −
	Cells	None.	
	Glob.	Normal content.	

During the interval between the above dates this patient received eleven intraspinal and thirteen intravenous treatments. (The latter were made necessary because there was a return of the blood Wassermann in August, 1914.) For more than twelve months he has been actively engaged in business and during this time he has exhibited no clinical manifestations of the disease of any kind whatsoever. The improvement in the pupillary light reflex, noted in June, 1914, is still apparent. The other objective phenomena are unchanged.

Case IX. Paresis. Man Aged 46.

It has been impractical to secure a serological status on this patient since April 14, 1914. At that time the spinal fluid Wassermann was negative, contained no cells, and no excess of globulin. Clinically, however, the change in his condition noted in May, 1914, has persisted without relapse until the present time. He is quiet and tractable and willingly co-operates with his physicians and attendants, a condition quite opposite from the one he was in when treatment was instituted. (Although treatment in this case was followed promptly by improvement it could not wholly be attributed thereto, since the change was of a character not infrequently seen in the ordinary course of the disease; *i.e.* from a wildly maniacal to a quiet passive state.)

Case X. Taboparesis. Woman. Aged 46.

		Cerebrospinal Fluid	Blood
May 17, 1914	Wass.	++ in 1.0 c.c. −Below.	−
	Cells	None.	
	Glob.	+, 0.2 c.c. (moderate excess).	
March 24, 1915	Wass.	Negative in all titrations.	−
	Cells	None.	
	Glob.	Normal content.	

This patient had one intraspinal treatment between these dates with salvarsan intravenously. She was discharged from the sanitarium nine months ago. Her mental condition, although not perfect, is better than it has been for five years, according to statements of members of her family. The marked emotional disturbances, delusions, and obsessions, which characterized her condition at the time treatment was instituted in August, 1913, completely disappeared twelve months ago and have shown no tendency to return. She is bright and cheerful, has a good memory, and shows no speech or emotional defect of any kind. Unfortunately the reaction she suffered after an intraspinal treatment in May, 1914, has caused a spastic condition of her lower extremities. This represents the only severe and permanent reaction that I have observed in more than twelve hundred treatments. In this instance it was probably due to an irritation of the roots in the lower extremity of the dural sac, caused in part by the excessive arsenical content of the serum employed, and in part, by post-operative mismanagement of the patient. It is also possible that there was a sudden intensification of the specific process in the cord resembling the Herxheimer reaction.

Case XI. Paresis. Man. Aged 44.

		Cerebrospinal Fluid	Blood
May 18, 1914	Wass.	++ in 1.0, 0.8, 0.6 and ± in 0.4.	−
	Cells	3 per cu. mm. −In 0.2 c.c.	
	Glob.	Normal content.	
April 21, 1915	Wass.	++ in 1.0, 0.8, and 0.6 c.c. −Below.	April 14, 1915 −
	Cells	2 per cu. mm.	
	Glob	Normal content.	

He had ten intraspinal treatments, ten intravenous, and thirty-four intra-muscular injections of mercury. Six months ago this patient developed an intercurrent disease which interfered with his treatment for over eight weeks. In the latter part of this interval he had one epileptoid seizure, similar to, although much milder than, those from which he suffered before the institution of treatment sixteen months ago. With the exception of this attack he has exhibited no clinical manifestations of the disease during this period. Mentally his condition is as good, and in many respects better, than it was when recorded in May, 1914. His speech,

retentive power, emotional tone, and insight are without defect. It will be noted that the serological picture in the spinal fluid is practically the same as in May, 1914, although it has fluctuated up and down during the past year.

Case XII. Taboparesis. Woman. Aged 33.		
June 12, 1914	Cerebrospinal Fluid	Blood
	Wass. ++ in 1.0, 0.8 and 0.6 c.c. – Below.	++
	Cells 3 per cu. mm.	
	Glob. +, 0.2 c.c. (moderate excess).	
Nov. 3, 1914		
	Wass. ++ in 1.0, 0.8 and + in 0.6 c.c. – Below.	++
	Cells None.	
	Glob. +, 0.2 c.c. (moderate excess).	

During this interim she received fourteen intraspinal and sixteen intravenous treatments. Although prior to September, 1914, there had been steady improvement in her condition, she failed utterly to respond either clinically or serologically after that time and began to grow worse. All treatment was discontinued. When the last analyses were made (Nov. 3, 1914) she was completely disoriented for time, place, and person. Delusions of grandeur were very marked. She had but little control over her extremities and her optic discs were becoming rapidly atrophic.

Case XIII. Spinal Syphilis. Man. Aged 46.		
May 15, 1914	Cerebrospinal Fluid	Blood
	Wass. ++ in 1.0 c.c. – Below.	
	Cells 3 per cu. mm.	
	Glob. +, 0.2 c.c.	
April 9, 1915		
	Wass. Negative in all titrations.	–
	Cells 2 per cu. mm.	
	Glob. ±, 0.2 c.c. (faint excess).	

Three intraspinal treatments were given. No salvarsan by vein and no mercury. The only evidence of the disease at this time, either subjective or objective, is a moderate degree of hyperactivity of the deep reflexes of the lower extremities. The sensory phenomena have entirely disappeared. The patient is on his feet ten to twelve hours each day.

Case XIV. Cerebrospinal Syphilis. Man. Aged 36.		
June 12, 1914	Cerebrospinal Fluid	Blood
	Wass. Negative in all titrations.	± (25°° inhib.)
	Cells None.	
	Glob. +, 0.2 c.c. (moderate excess).	
March 27, 1915		April 16, 1915
	Wass. Negative in all titrations.	–
	Cells None.	
	Glob. +, 0.2 c.c.	

This case has not received treatment of any kind. He has steadily gained in every respect since the examination recorded in June, 1914. His legs are stronger. The sensory changes have entirely disappeared. There is a moderate degree of bladder insufficiency when it is distended, but ordinarily he experiences no difficulty in retaining and voiding his urine.

Case XV. Tabes. Man. Aged 47.		
May 20, 1914	Cerebrospinal Fluid	Blood
	Wass. ++ in 1.0, 0.8, 0.6, 0.4 and 0.2 c.c.	Not made
	Cells 40 per cu. mm.	
	Glob. ±, 0.2 c.c. (faint excess).	
July 28, 1914		
	Wass. ++ in 1.0, 0.8, 0.6 and – below.	Not made
	Cells 16 per cu. mm.	
	Glob. ±, 0.2 c.c. (faint excess).	

One intraspinal and one intravenous treatment were given between these dates. It has been impossible to obtain a more recent serological status. Four weeks ago the patient reported that he had not had a return of the attacks of abdominal distress which constituted his chief complaint at the original examination.

Summary.—Out of the fifteen cases thirteen show a complete disappearance of all subjective manifestations, with improvement in the objective signs in one way or another, for an average period of one year, while one showed moderate improvement only, and one failed utterly to respond to treatment. Of the total number eleven cases (6 tabes; 3 paresis; 1 syphilitic myelitis; 1 cerebrospinal syphilis) show spinal fluids negative to the Wassermann reaction in all titrations, with normal cell and globulin contents; two remain positive, and in two recent analyses could not be secured. Ten cases (4 tabes, 4 paresis, 1 syphilitic myelitis, 1 cerebrospinal syphilis) show negative Wassermann reactions in the blood; three remain positive, and in two recent analyses could not be secured.

As to the value of the treatment when systematically and judiciously employed, further comment seems unnecessary. To those familiar with the resistive and tenacious character of these diseases it will at once be evident, from a study of this and other reports, that the intraspinal method offers far more in the way of therapeutic possibilities than the use of mercury and salvarsan intravenously alone. That the latter are of the greatest importance is readily conceded, but I have seen but few instances, probably less than 2 per cent. of my cases, in which their employment alone, even when given with heroic intensity, has accomplished a complete eradication of the laboratory evidences of syphilis in the spinal fluid. No matter how striking the clinical improvement may be the treatment has been inadequate unless this has been accomplished.

As in the treatment of all other disease processes the success attainable is largely dependant upon the promptness with which the infection is recognized, and the discretion exercised in employing curative agents or other measures to combat it. In neurological syphilis the field of greatest opportunity lies in instituting treatment in the *predestructive* stage. With this end in view the spinal fluid should be subjected to a rigid examination in every case presenting indefinite or transitory symptoms referable to the central nervous system, whether the patient gives a history of syphilis or not and regardless of the existence of a negative Wassermann reaction in the blood. Once recognized, of equal importance is the manner of treatment. Every case must be carefully studied as a separate problem, and numerous factors, besides the mere presence of a specific infection, must be considered.

The preparation of the serum consists of much more than simply adding salvarsan to it, as has frequently been assumed. Each step in the technique has definite scientific reasons back of it and it should not be intrusted to any one unable or incompetent to give the painstaking attention necessary in handling a drug, which, although possessed of great curative properties under certain conditions, is nevertheless highly toxic and therefore dangerous under irregular slipshod laboratory methods.

105 West Seventy-Second Street.

GLUTEAL MYOSITIS—A CONDITION NOT HERETOFORE DESCRIBED.

By NORMAN SHARPE, M.D.,

AND

PERCY WILLARD ROBERTS, M.D.,

NEW YORK.

There have recently come to our attention a number of cases of inflammatory reaction in a certain group of the muscles of the hip, namely, the glutei and the tensor fasciæ femoris, which is characterized by pain, tenderness, and stiffness in the entire group or parts of it, and by disability more or less severe, and in all of them the true condition had been overlooked in previous examinations.

These cases, because of constant errors of diagnosis, merit close study and careful interpretation.

Inflammation of muscle is, of course, a well recognized condition. Stockman[1] in 1904 described a form of muscular inflammation accompanied by hyperplasia of the connective tissue, tendon sheaths

and the nerve sheaths. It was characterized by pain, stiffness and the development of hard nodules in the affected muscles or in their tendinous expansions or attachments. At times instead of nodules he found a doughy induration of the affected muscles which was easily palpable. Stockman called the condition a chronic rheumatism of the muscles, and gave as the causes: acute rheumatism, influenza, gonorrheal arthritis, sore throat, and the exposure to cold and wet. In other words, he held it was due to a toxin. He did not believe that gout or errors of diet were causative factors.

Knowles[2] reported a case of nodular fibromyositis in a woman following a severe attack of malaria. The tender nodules were found in the lumbar aponeurosis over the sacrum. Heat and massage cleared up the pain, but did not remove the nodules.

Gowers[3] speaks of a chronic inflammation of the lumbar and hip muscles which he calls a myalgia due to "fibrositis," a condition of hyperplasia of the fibrous tissue of the affected muscles. He says this inflammation may spread to the nerve sheath and give rise to a sciatica. Contrary to Stockman, he finds these inflammations in those who inherit a gouty diathesis. This inflammation Gowers speaks of as involving the tendinous structure over the sacrum rather than the muscles of the hip.

Telling[4] has also described fibromyositis, the essential morbid process of which he says "is an inflammatory exudation into the fibrous tissues in almost any situation in which fibrous tissue is found." This exudation, which varies from a slight doughy induration to the formation of definite hard nodules, leads to swelling and thickening of the affected area and is accompanied by pain. Telling found these indurations and nodules in the lumbar region, retrocolli and temporal muscles (causing indurative headache), and also in the pectoral and abdominal muscles. He considers the condition a chronic "rheumatism" of the muscles, and gives as causes, influenza, cold and wet, gastrointestinal disturbances, and constipation—in short, a toxemia. After the indurations are once formed a fresh attack is brought on by violent exertion, cold and wet, or acute indigestion.

Petren,[5] in an article on "Sciatica and Morbus Coxæ Senilis," mentions some cases in which the symptoms were those of a rheumatic sciatica, but the only tender points found were over the gluteus medius muscle. He gives two possible explanations of this condition: (1) That the symptoms were due to a myositis of the gluteus medius followed by compression of the nerve, or (2) that the inflammation may have extended from the muscle to the nerve sheath. As to the cause of the tenderness in the gluteus medius he is not definite, but does not exclude neuritis of the superior gluteal nerve, as in his cases the tender point corresponded to the position of the nerve as it passes through the great sciatic notch under the posterior border of the gluteus medius. Petren evidently considered the muscle inflammation as a part of the sciatica or as a possible cause of the sciatica, and did not regard the myositis as an independent condition.

Luff[6] uses the term "fibrositis" to cover various inflammations, such as muscular rheumatism, lumbago and Dupuytren's contractures, and says that this condition of inflammatory hyperplasia of the tendons and muscles is not a sequel of acute rheumatism and has nothing to do with that disease. Also, as opposed to Gowers, he believes it has no relation to gout, but at times is due to a "self-generated systemic poison owing to the inability of the gastrointestinal tract to deal properly with the various articles introduced into it." Other causes he gives are exposure to cold, damp or wet, local injuries, as sudden and severe strain, tonsillitis, pharyngitis, and influenza.

Yawger[7] has described a form of myositis in the gluteal region which, he says, is "rheumatic" in origin or due to autointoxication. He places this rheumatic myositis as occupying part of the gluteus medius muscle with perhaps slight involvement of the gluteus maximus and minimus. From here the symptoms may spread to the sciatic nerve, due to compression by the inflamed muscle, or to a direct inflammation of the nerve sheath from the muscle.

Knapp[8] describes a form of myositis traumatica occurring in the muscles of the neck, the lumbar or gluteal region, in which the pain comes on at night. This is due, he says, to prolonged extension or hyperextension of the muscle caused by faulty posture in bed, or by sagging of the bed. He says it is not a systemic nor constitutional condition, nor due to infection. If the pain is in the neck, it is due to faulty arrangement of the pillows, and if in the back, or gluteal region, is due to a sagging bedspring. He cured his patients by making them sleep on the floor or on a firm bed, or by proper arrangement of the pillows.

The type of myositis that we are reporting differs from those cited above in several particulars.

1. It is sharply localized, being usually limited to the gluteus medius and tensor fasciæ femoris, and sometimes involving the gluteus minimus and the gluteus maximus to a slight extent. The pain and tenderness is circumscribed with no involvement of other muscles of the body.

2. In none of our cases did we find any induration. Although all of them were examined repeatedly by both of us, we did not find the soft "doughy" exudation, the brawny subcutaneous induration, or the nodular masses so emphasized by other writers. Compared with the same tissues of the opposite side, the affected muscles felt normal, except for occasional tension and the presence of pain and tenderness. It is true that in several of our cases palpation disclosed prominences in the body of the muscle that might easily be mistaken for inflammatory indurations. However, these could be made to disappear by pressure of the fingers and were due to temporary spasm of the muscle fibers.

3. None of the causes given by the writers quoted, with the possible exception of autointoxication from gastrointestinal disturbances, seems to have been operative in our cases. Least of all does "rheumatism" seem to be a factor. It is scarcely conceivable that an attack of muscular rheumatism will confine itself to a small group of muscles without demonstrating its presence elsewhere in the body. Influenza, tonsillitis, pharyngitis and gout were excluded by the histories of the cases, and we do not think the toxins of these diseases have a predilection for the gluteal region. Many of the cases showed evidences of gastrointestinal indigestion, such as coated tongue, dry, reddened throat, and constipation. The etiology will be further elaborated in the discussion of the cases.

As the condition is not fatal, but merely more or less disabling, the points for consideration are diagnosis and treatment. In the majority of our cases the trouble was of some weeks' or months'

standing, and a correct diagnosis had not been made. The patients had gone from doctor to doctor and from hospital to hospital without relief. The constant pain and soreness had reduced many of them to a state of semi-invalidism. The diagnoses which were given them included muscular rheumatism, sacroiliac joint trouble, lumbago, coxitis and sciatica. They had been strapped with adhesive plaster, cauterized, blistered, treated with galvanism or static sparks, baked, dosed with aspirin and salicylates, with little or no improvement. Scarcely a case escaped the diagnosis of "sciatica" at one time or another. In hospital records the diagnosis of "sciatica" is frequently seen, but in our experience, which includes observation of the material of several large neurological and orthopedic clinics, sciatica, though not rare, is uncommon. In the last six months we have seen but one case of true sciatic neuritis and six cases of the milder form—the so-called sciatic neuralgia. There can be no doubt that "sciatica" is a diagnosis too often carelessly made. It should not rest merely upon the presence of pain elicited by pressure of the thumb in the popliteal space or pain on exhibition of Lesegue's sign (flexion of thigh with leg extended) as is so often the whole basis of diagnosis.

Of our cases, which number sixteen, the reports of six will be given. The remaining ten gave similar histories and symptoms, examinations showed similar conditions and their behavior under treatment was the same. All the cases were submitted to a searching neurological and orthopedic examination. Skiagraphs were made of many of them to eliminate bone or joint lesions. For sake of brevity in the cases reported only the positive findings, together with the more important of the negative findings, are given.

Case I.—J. K., age 41, tailor. Never had rheumatism. No history of trauma. In his work he constantly flexed and twisted body sideways as he stood. Sixteen years ago he had pain in left hip which lasted one year. This attack was similar to present one. For some years after his first attack he sat while at his work. Does not exercise. Came to hospital June 17, 1914, complaining of pain in left hip and back of thigh which began two months previously. Pain only on motion, which was very noticeable on turning in bed. Except for the pain, he felt well. Was told he had sciatica and was treated without improvement.

Examination: Patient has what we might call "sedentary muscles," soft and flabby. General neurological and orthopedic condition normal; tongue clear; not constipated; no tenderness over sciatic nerve; Lasègue's sign negative; no tenderness in lumbar muscles or in spine; extreme tenderness to pressure over the anterior half of gluteus medius and some over tensor fasciæ femoris; sacroiliac and hip joints normal.

Treatment: Deep and hard massage of the affected muscles three times a week for three weeks. Discharged at that time with no pain and no tenderness.

Examination in November, 1914, five months later, showed no return of symptoms and no tenderness in muscles.

Case II.—S. H., age 39, tinsmith. No rheumatism nor trauma; gonorrhea twelve years previously. Had similar pain fourteen years ago in right hip which lasted for ten months. Had no pain in leg. His work requires much stooping and bending. Six months previous to coming to hospital pain began back of right hip and gradually grew worse. Pain more acute on motion after sitting; pain also present when lying in bed if he moved; no indigestion and not constipated. Was treated for two months for sciatica.

Examination: Neurological and orthopedic condition normal and x-ray negative; Lasègue's sign negative; no tenderness over lumbar region or over spine or sciatic nerve. Extreme tenderness to pressure over the right gluteus medius and maximus; the tender area extended from just below the iliac crest (the origin of the muscles) almost to their insertion in the femur. No indurations or nodules found.

Treatment: Deep massage (kneading) of the affected muscles. Patient could come only twice a week for treatment. Massage begun October 20, 1914.

Discharged two months later, December 28, 1914, cured. No stiffness or tenderness. Had fifteen treatments.

Case III.—L. S., age 23. Bookkeeper. No history of rheumatism nor trauma. In his work he frequently lifts and moves heavy books. No indigestion; not constipated. Six months before coming to hospital pain began back of right hip and rapidly grew worse. Was treated six months for sciatica; had aspirin, baking, electricity, etc. No improvement.

Examination: Slightly built man with poor muscular development; general neurological and orthopedic condition normal; no tenderness over sciatic nerve; Lasègue's sign present; but pain is referred to gluteal muscles; extreme tenderness to slight pressure over gluteus medius and minimus, x-ray showed the bony pelvis normal. Sacroiliac joint normal, no tenderness over spine or sacrum, and none in the lumbar region, or over the point of exit of the superior gluteal nerve.

Treatment: On account of extreme soreness a plaster-of-Paris spica was applied from waist to knee and worn for three weeks. Slight pain the last week of wearing cast and for five days following its removal, during which time massage was given. Some pain after five days, but with massage it gradually disappeared. Was under treatment from October 23 to December 14, 1914, the first eighteen days of which time he wore the cast. Massage was begun November 10 and his further history was one of gradual improvement until he was discharged in December, cured with no pain or tenderness. Eighteen treatments in all were given.

Case IV.—M. D., age 45. Waiter. No history of rheumatism nor trauma. Has had flat feet for years and wears arch supports. He lifts and carries on his left arm heavy piles of dishes constantly. No indigestion or constipation. Two weeks before coming to hospital, while in good health, he had pain back of left hip which gradually grew worse and confined him to bed. The case was diagnosed first as "rheumatism," then sacroiliac joint subluxation, then sciatica. Was kept in bed two weeks, but no improvement. Had no pain in bed unless he moved. Pain keeps him from working.

Examination: Heavily built male, with flabby or sedentary muscles. General neurological and orthopedic condition normal, except for the flat feet which metal arches adequately support. Slight tenderness over posterior muscles of left thigh, but none over sciatic nerve or over great sciatic notch. Extreme tenderness over tensor fasciæ femoris and gluteus medius. The x-ray showed bony pelvis normal. No tenderness in the sacrum or lumbar region, nor over the superior gluteal nerve.

Treatment: Deep massage of the affected muscles begun November 2, 1914. Had twelve treatments in all. Gradual improvement. Against advice stopped treatment December 5, 1914, to go to work. No pain and but little tenderness in these muscles. Not entirely cured.

Case V.—E. S., age 46; saleswoman. Came to clinic June 2, 1914. No rheumatism or trauma. One ovary removed three years ago. Menopause two years ago. Drank one-half pint of whisky daily for four years; none for last four months. Has coated tongue and is constipated. Seven months ago pain began back of left hip, causing limp which has persisted to the present time. One month ago pain began back of right hip and has gradually grown worse. Says she has had no weakness of legs. Pain worse on motion, and stiffness present after sitting for a time. Diagnosis of sciatica was made and she has been treated for that for last three months.

Examination: General orthopedic and neurological condition normal. No sensory changes, no drop foot, no weakness of legs, nor other signs of an alcoholic neuritis. Sacroiliac joint normal, no pain or tenderness in lumbar region or sacrum. Extreme tenderness on pressure over the gluteus medius in its upper half and the anterior part of the gluteus maximus of both sides, but much more marked in the left. No tender points over the right sciatic nerve; tenderness to pressure of the left sciatic only in the gluteal region; Lesègue's sign absent on the right side, present on the left, but pain is referred to the gluteal region only. No indurations found in the affected muscles.

Treatment: Sodium salicylate and Cascara for constipation. Deep massage (kneading) of the affected muscles begun June 2, 1914. Also applications of heat. Was under treatment six weeks. Had eighteen treatments. Discharged cured, July 17, 1914. No limp, no pain or tenderness. Seen December, 1914, six months later, still free from pain and tenderness.

Case VI.—S. D., age 34; newsdealer. No history of rheumatism or trauma. Troubled with indigestion and constipation. Ten years ago had pain in right hip which he says was similar to present trouble. Cured by hot mud baths at Odessa. Eight months ago had pain back of left hip, extending into left thigh. Cured by massage in two weeks. Three months ago had similar trouble in left hip. He stopped work and his trouble got well of itself in two weeks. Patient's work obliges him to frequently lift one hundred pound packages of newspapers. Four days before coming to us he had pain and stiffness back of left hip, extending toward the anterior spine of the ilium. This pain has gradually become worse and causes him to limp. Was told he had muscular rheumatism.

Examination: Patient rather well built, but muscles flabby; tongue coated and throat dry. General neurological and orthopedic condition normal, hip joint and sacroiliac joint normal. Pressure over sciatic nerve in middle of thigh reveals slight tenderness, but no other signs of sciatic involvement. Skiagraph shows sacralization of the fifth lumbar vertebra, but pelvis is otherwise normal. Extreme tenderness over gluteus medius and some over the gluteus maximus. Lasègue's sign positive; but pain is referred to gluteal muscles. Was treated by massage, but at end of one week tenderness was increased and gluteus medius and tensor fasciæ femoris on opposite side were also tender. There was also more tenderness over left sciatic nerve. A left spica plaster cast was applied and worn for three weeks. Was given small doses of sodium salicylate as intestinal antiseptic. Cast removed and deep massage begun November 27, 1914. Limp disappeared and cane discarded twelve days later. The masseur combined muscle stretching with the kneading. His after history is one of gradual improvement. The first week in January, five weeks after treatment was begun, he could walk three miles without pain, though he had some soreness in the affected muscles afterward.

Of the remaining ten cases some have been discharged cured, some have disappeared, and the others are still under treatment. It is somewhat difficult to keep clinic patients under observation, for as soon as their severe pains are relieved some of them disappear.

Bearing in mind the mechanics of the glutei, and especially of the medius and minimus, it will be observed that all of these patients were calling these muscles into play for unusual effort. As a group, the glutei are chiefly concerned in maintaining the trunk erect on the lower extremities or of raising it from the stooping position. The gluteus medius and minimus are important rotators of the trunk upon the hip when the leg is fixed, or of the thighs when the trunk is a fixed point. Therefore in lifting heavy weights when the body is flexed, in turning the trunk upon the thigh while bearing a heavy burden, in lifting at a lateral disadvantage or carrying weights on one side, there is placed upon the glutei a severe strain which may be sufficient to cause a myositis in a flabby muscle. It is our experience that a single strain does not give rise to this condition, but that it is a repetition of the injury to a muscle which has been overtaxed and has not recovered from its initial lameness which produces disability.

In reviewing the reports of these six cases (and the same is true of the remaining ten cases) several features appear with noticeable prominence:

1. Though in many of these patients the muscles in general were fairly well developed, yet in all of them the muscles of the limbs and lower trunk were soft and flabby, showing lack of exercise—the "sedentary" muscles.

2. The work of many of them required frequent repetition of certain movements (twisting the body or stooping, or lifting heavy weights, or carrying weights on one side) as in Cases I., III., IV. and VI.

3. About one-third of these patients gave a history of indigestion and constipation, but the majority were free from symptoms of digestive disturbances which might cause intestinal toxemia.

4. In the entire sixteen cases the diagnosis was not made in previous examinations. Sciatica was the explanation of the symptoms and treatment for sciatica, varied as it was, did not give relief.

5. Acute rheumatism was not a forerunner or a cause in any case. Careful histories of all patients were taken, though many negative points are omitted in the synopses given. In none of them were influenza, "colds," or sore throat of sufficiently recent date to be considered as a cause.

In our opinion the cause of this gluteal myositis is excessive strain placed upon muscles which are in a condition of hypotonus, or in other words, excessive use of muscles which are below par. Thus in Case IV., a waiter (who carried heavy piles of dishes on left arm) excessive use of the gluteus medius and minimus was required to hold the trunk to the left side in order to maintain balance. In Case VI. (a man who frequently lifted heavy packages of papers) the gluteus maximus was extensively used to raise the trunk and the pain later appeared on the opposite side. Of course in persons of vigorous physical habits, such strains or excessive use would have no ill effects on the muscles, but none of our patients was of this type. In two of the cases reported, Nos. V. and probably VI., and also in some of the remaining ten cases, we do not exclude autointoxication, as evidenced by coated tongue, dry throat, history of indigestion and constipation, as a predisposing factor, though it certainly was not the cause. The majority of the cases had no digestive trouble, and the other muscles were free from pain and soreness.

In three of the sixteen cases, No. VI., and two others, symptoms of sciatica later appeared. This was probably due to compression of the nerve by the inflamed muscles or to extension of the inflammation to the nerve sheath. The late development of the nerve symptoms tends to confirm this view. However, the nerve involvement was slight, although the pain was severe and extended down into the ankle and muscles of the calf. For two or three days rest in bed removed the pain, so that massage and stretching of the gluteal muscles could be resumed. In the other cases there were no symptoms of involvement of the nerve at any time.

No attempt was made to secure sections of the muscles for laboratory examination, as it has been shown that excision may cause changes in the muscular tissue secured and render study of it valueless.

Of the conditions other than sciatica to be excluded in arriving at a diagnosis of myositis are: coxitis, inflammation of the lumbosacral ligaments, osteoarthritis of spine or hip, neuritis of the superior gluetal nerve and sacroiliac joint disease. Neuritis of the gluteal nerve is determined by pressure over its point of exit from the sciatic notch under the posterior border of the gluteus medius and by the fact that neuritis rarely occurs in this nerve alone without involving other nerves of the lumbosacral plexus. Disease of the sacroiliac and hip joints may be excluded by the usual clinical tests and the *x*-ray.

Treatment.—The treatment that we have found most satisfactory for this condition is massage, deep and hard, carried out over a period of weeks. General massage is useless and ordinary massage or rubbing of the affected muscles is of little benefit. Massage must be of the kneading type and as severe as the patient can stand. In those cases where the pain and tenderness was so marked as to exclude massage, we achieved good results by enclosing the affected hip in a plaster-of-Paris spica which was worn until the acute soreness had disappeared, as in Cases Nos. III. and VI. Deep massage was then begun and could be borne without great discomfort. Those patients suffering from gastrointestinal disturbances were treated by appropriate remedies and regulation of diet. Many of these patients, owing to the pains long endured before the condition was recognized, became decidedly neurasthenic. Case No. VI. came into the clinic with a cane, limping and unable to stand erect, and with the most extreme tenderness in the affected muscles. After weeks of treatment and long after he had discarded his cane and limp could endure severe kneading of the gluteal muscles, and walked three miles daily without pain, he assured us he felt "about the same."

After all tenderness and soreness of the muscles have disappeared there will remain some stiffness, due probably to hyperplasia of the tendinous structures of the muscle. This is combated by muscle stretching and various gymnastic movements which readily suggest themselves and can be carried out by the patient in his home.

In several stubborn cases, as useful adjuvants to massage, we have employed hot baths, applications of dry heat and strong static sparks; but in the main we rely solely upon massage.

Summary.—There is a type of inflammation of the muscles of the hip, especially of the gluteus medius and tensor fasciæ femoris, and less frequently of the gluteus maximus, which has not in the past been generally recognized. These cases present certain prominent symptoms common to all of them which are more or less disabling, and they possess an especial interest by reason of their almost constant confusion with sciatica and also by the fact that treatment instituted for sciatica will not cure them.

Gluteal myositis is not "rheumatic" in origin, is not a sequel of influenza, tonsillitis, faulty posture in bed, and is not dependent on gastrointestinal disturbances. It is due to excessive strain placed upon muscles which are unfitted to bear it. The treatment is deep massage, vigorously continued until all soreness has disappeared. Of our sixteen cases, in which the condition had been present for a period varying from several days to several months, a number were cured in two to three weeks, but the majority required four to ten weeks of treatment.

The frequency of the occurrence of myositis is indicated by the fact that since concluding our observations on the sixteen cases referred to above, twelve others have come under treatment, all of which had previously gone unrecognized. So numerous have these cases become in our field of observation that we feel justified in urging the examination of all patients complaining of symptoms in the sciatic nerve, or about the sacroiliac or hip joints, for the presence of myositis of the glutei.

The foregoing is of the nature of a preliminary report which will be amplified later with deductions from a larger series of cases.

HISTORY OF A CASE OF JACKSONIAN EPILEPSY.*

BY VICTOR E. WATKINS,

FIRST LIEUT. MEDICAL RESERVE CORPS, U. S. ARMY, HENRY BARRACKS, CAYEY, PORTO RICO.

THE following case of Jacksonian epilepsy presents some unusual features, particularly with reference to the acute onset of the condition, the steadily increasing frequency and severity of the convulsions, and the prompt disappearance of all symptoms upon removal of the cortical irritation.

A. B., private, admitted to the Post Hospital, Key West Barracks, May 20, 1914. Family history negative. In April, 1909, he was injured on the left side of the head by the premature explosion of a blast in a coal mine at Wilkesbarre, Pa. He was rendered unconscious and taken to hospital where he was operated on for fractured skull. Was in hospital four weeks. Patient states he had two fits in one day in 1912, which he attributes to drink. Records show he was admitted to this hospital April, 1912, diagnosis, "Acute alcoholism." Present illness. Was taken suddenly with convulsions at his home outside of post about 3.00 P. M., May 19, 1914. Had been on duty in company kitchen up to noon of that day. On admission he was having frequent convulsive seizures involving corner of mouth, right side, right eyelid, right arm, and *left* leg, and then becoming general in character. There was a large depressed scar 1½ inches posterior to and 1¾ inches above the external angle of the orbit on the left side. Heart and lungs normal. Diagnosis. Jacksonian epilepsy.

Patient had not been feeling real well for three or four days prior to beginning of attack, but had continued at his duties as company cook. He went home (he is married) shortly after noon on May 19, 1914, at about 3.00 P. M. that day was taken with severe and frequent convulsive seizures.

May 20, 1914.—Partial paralysis, right side. Mental condition dull; would protrude tongue when told to do so, and would answer simple questions. Convulsions were frequent and severe and invariably took the following order: (*a*) twitching of muscles corner of mouth, right side; (*b*) twitching of right eye lid; (*c*) contraction of brow; (*d*) turning of head strongly to right; (*e*) raising of right arm above head with slight flexion of elbow; (*f*) raising of left leg with slight flexion of knee; (*g*) twitching of right thigh and leg with marked extension of right foot; (*h*) general severe convulsive movements of entire body.

There was no frothing at the mouth, no biting of tongue, and no loss of consciousness after fit, the attack ending in a deep sighing respiration and deep flushing of face. No deviation of tongue or other evidence of facial paralysis.

May 21.—Complete loss of voluntary movements on right side of body. Retention of urine; bowels constipated. Convulsions became more frequent and severe. Mental condition very dull. Would protrude tongue when asked *any* question. While he would not talk, speech was not lost as he uttered articulate words when being catheterized. Patient's general condition growing steadily worse and convulsions occurring with greater severity and more often, operation was decided upon.

May 22.—Operation at 11.30 A. M. Anesthetic, ether.

*Published by authority of the Surgeon General of the Army.

Scalp was laid back, exposing skull under old scar (see above) and skull trephined in two places ¾ inch apart over the lower part of the motor area, left side. Intervening bone removed and also small piece of bone immediately in front of anterior trephine opening. This procedure exposed a cyst about the size of a small hen's egg, located approximately at lower end of precentral gyrus. Cyst was opened and drained. Patient stood operation well and came out from anesthetic without nausea.

May 23 and 24.—The mental condition and paralysis remained about the same. Convulsions recommenced at 7.45 P. M. the day of the operation, and continued with increasing frequency. There was considerable discharge of serum from the wound during the first 24 hours.

May 25.—The convulsions were progressively more frequent and severe this morning. The regular order cited above was followed, but the face instead of being flushed at the end of the convulsion became cyanotic. They were so frequent at times as to appear to be continuous. Drainage from the wound had practically stopped, and it was believed that the cyst had refilled. The scalp flap was laid back under ether, the intention being to excise the cyst completely, but profuse and alarming hemorrhage occurring, the cyst contents were quickly but thoroughly evacuated by the finger, and the cyst cavity packed with gauze. Recovery from anesthetic uneventful. Patient had a convulsion at 10.55 A. M., and another, not very severe, at 1.20 P. M.

May 26.—Patient voided urine voluntarily this morning for the first time since admission to hospital. Slight voluntary movements of right leg. Mental condition confused, but patient talks. He developed a polyuria, voiding 3,120 c.c. in 24 hours. No abnormal constituents. Dressings saturated with serum. Had a very slight convulsion at 12.10 P. M. Bowels moved voluntarily at 3.00 P. M.

May 27.—Quite free movement of right leg, and slight movements of right arm this morning. Mental condition much improved, and patient talks intelligently, but memory for present events impaired. Polyuria continued today. Urine voided and bowels moved voluntarily. No convulsions. Dressings saturated with serum.

May 28.—General improvement in patient's condition. No convulsions today.

May 29.—Improvement continued; free use of right arm and leg. Gauze packing removed from cyst cavity, without anesthetic, no hemorrhage, but escape of large quantity of serum. No convulsions today.

May 30.—Dressings saturated with serum this morning. Polyuria not so marked. No convulsions.

May 31.—Escape of much serum into dressings. Has free use of right arm and leg, but cannot coordinate for finer movements, as writing. Mental condition good and memory returning. No convulsions. Urine normal in quantity.

The patient's condition improved rapidly from day to day, and by June 5 he had free and normal use of all his faculties, including coordination for writing and other finer movements.

The cyst cavity was kept packed with gauze until all discharge of serum ceased, when the gauze was removed and scalp wound allowed to heal. During the height of the convulsions full doses of bromide and morphine, and inhalations of chloroform and amyl nitrite were administered, but without effect either upon the force or frequency of the attacks.

Patient has no recollection of being brought to hospital. The aura in this case was the twitching of muscles at the corner of the mouth, right side, the patient stating that, at the beginning of the attack, he realized when a convulsion was coming on by this sign. He was returned to duty June 22, 1914.

Attention is invited to the following points:

1. The sudden onset of the convulsions.

2. The rapidly increasing frequency and severity of the convulsions. He had 256 convulsions from admission to hospital until secondary operation.

3. The prompt disappearance of the convulsions after thorough evacuation of cyst contents. He had a convulsion at 10.55 A. M. May 25, about five hours after operation, another slight one at 1.20 P. M., same day, and a third and last one, amounting to nothing more than a slight muscular tremor, at 12.10 P. M. the day following.

4. The rapid disappearance of the mental symptoms and of the paralysis.

5. The failure of drugs either to control or to modify the force or frequency of the convulsions.

6. The transient polyuria.

The patient has been under observation for ten months since operation, the last nine months performing all his duties as a soldier. His mental and physical condition is normal and there has been no return of the convulsions, which would seem to show that in acute cases of Jacksonian epilepsy the "epileptic habit" is not necessarily developed.

This case illustrates the fact that the motor area of the brain can adapt itself to very slowly increasing pressure without symptoms, the cyst in this case reaching considerable size before cortical irritation was manifested by convulsions.

While observation of this patient extending over a period of two years or more can only determine what the ultimate result will be, it is believed that the acuteness of the condition and the prompt and complete disappearance of the symptoms, makes a favorable prognosis justifiable.

SUGGESTION NARCOSIS.

By A. L. BECK, M.D.,

AND

A. W. HOYT, M.D.,

NEW ROCHELLE, N. Y.

THE intention of the case recorded below was to secure the nerve blocking of Crile by mental rather than material means; to reduce to a minimum the impression on the brain through the eye and ear through direct contact; to narrow the mental horizon.

The patient was a young woman, age seventeen, extremely nervous, easily upset by little things. In June, 1912, developed bronchial asthma. At that time was in poor condition physically, thin, anemic, constipated, and nervous.

The nose was first examined in October, 1912, for the purpose of determining whether or not a nasal abnormality was an etiological factor which might give rise to the asthmatic attacks. The nasal septum was seen to be markedly deviated and there was moderate enlargement of the right middle turbinate bone, with contact between it and the septum. Nasal breathing was very much impaired.

On account of poor general condition of the patient, and an unwillingness to undergo any extensive operation, it was thought best to see what could be accomplished by the simple procedure of removing the anterior third of the right middle turbinate to relieve the pressure. This was done under anesthesia with cocaine 4 per cent. and adrenalin. The operation was a trying one, owing to the weeping, sudden movements, and general lack of control of the patient. The after effects were those of extreme shock and prostration, causing much anxiety at the time. The patient was told that, although she might look for some relief, which in fact she obtained, more would have to be done to be of any permanent benefit. The patient was not seen again for sixteen months, during which time she continued having asthmatic attacks with, perhaps, diminished frequency. During this period of time, we were informed, an intranasal operation was attempted by another surgeon, but was abandoned, as the patient went into collapse during the preliminary packing.

Early in March, 1914, the patient returned to us and sought consultation, and stated that she was willing to undergo an operation, providing a general anesthetic be administered. This indicated plainly the mental attitude of fear of operation. While a submucous resection of the septum has been and is being performed under general anesthesia, it is never as smooth an operation as when done under local anesthesia with the addition of adrenalin, owing, of course, to the bleeding which occurs under general anesthesia.

Therefore, we decided to use suggestion or hypnosis, combined with the usual method of packing with a cocaine substitute and adrenalin, owing to extremely poor general condition and the obstacles to which general anesthesia give rise.

Preliminary hypnotic condition was induced March 26, 1914, with post hypnotic suggestions of good sleep at night, calm mind and freedom from anxiety about the operation to be performed two days later.

At the time of the operation, patient was hypnotized in reception room and walked to operating room; nose was packed with cotton pledgets saturated with a solution consisting of alypin 10 per cent. and adrenalin 1/8000. During the resection of the septum and removal of the remaining portion of the right middle turbinate, the patient would speak from time to time. Some of her expressions were "That stuff is running down my throat," "My throat is dry," "You can't get the bone out and I am glad," "There goes the bone and I don't care." On being told to go more deeply asleep, she replied, "I would if they would stop fussing with my nose." This "fussing" was the removal of pieces of the ethmoid plate where the anesthesia was not deep, and also the removal of the maxillary spine, where pain is often felt. The operation lasted over two hours, including preliminary packing. During this time the face had a good color, and the lips red, in fact, color was deeper than normal, pulse regular and full at 96. It seemed to us that bleeding during the operation was freer than in the usual submucous resection done under cocaine. Whether this was due to cerebral congestion from the hypnotic condition, or from the alypin, we could not determine. At the completion of the operation the patient was removed to an adjoining room and was aroused. Ten minutes later she walked to a taxicab, rode home and then walked up one flight of stairs to her bedroom; all this in a perfectly calm mental condition. Convalescence was uneventful. It appeared that the non-observance of mental impression during the operation was about what one gets under light general narcosis by ether or chloroform where the patient may cry out and complain but later denies that he knew anything of the passing event, with the advantage that the postoperative condition is infinitely better.

This case is reported that other operators, with difficult cases, may not overlook this efficient aid.

On March 17, 1915, the patient was requested to present herself at the office. She asserts that her breathing became excellent as a result of the operation, but that it was several months after the operation before she realized the great benefit to her general health. At the present time she weighs 130 pounds, has lost the pallor of the skin, has a good appetite, sleeps well, and has had no more asthmatic attacks. This has all been verified by her family physician who has been called occasionally to see other members of the family.

Hallaver found this method effective in 90 per cent. of more than three hundred cases in Strassman's gynecological clinic in Berlin for curetting, dilation of cervix, removal or retained membranes after abortion, amputation of cervix, replacing a retroflexed uterus, cauterization of carcinomata and caruncles, and many others.

In obstetrical cases this method has proved of value, "even very nervous cases lying quietly and comfortably during the painful second stage of labor, and neither then nor afterwards having any appreciation of the pain of childbirth." Combined with the initial hypodermic of the twilight sleep, this method should be ideal. The memory of pain would be annulled, shock would be avoided and duration of labor would be decreased instead of increased, with consequent benefit to the child.

Medicolegal Notes.

Malpractice—Excessive Damages.—A doctor who is called to treat an injured person cannot be held to answer for the suffering caused by the original injury, but only for the suffering caused by his own negligent acts. The original injury, in so far as the attending surgeon is concerned, is as if it were self-inflicted. All hurts requiring surgical care are presumptively painful and tormenting. In an action for malpractice in not seasonably setting a fracture of the femur it was held that it can be judicially noticed that a compound fracture of the lower limb and a fracture of the femur are painful hurts, and will occasion long suffering although treated with the best of surgical skill. It was held that the defendant was not responsible for the original injury, or an infection which prolonged the healing of the lower fracture indefinitely and which made a surgical operation upon it necessary, or for the six to twelve weeks during which the bones might have knit under the most skillful treatment had there been no infection. Commenting upon the jury's award of $7,385 the appellate court said that it was constrained to believe that the jury, in pity for the plaintiff, visited the whole consequence of her hurts and suffering upon the defendant without appreciating the demand of the law that the plaintiff bear her share of what the court called "the misfortune which angry chance threw over the unlucky parties to the action." The verdict was held to be excessive to the extent of $2,000.—Cranford vs. O'Shea, Washington Supreme Court, 145 Pac. 579.

Cause of Injury—Evidence—In an action for personal injuries caused by falling into an unprotected excavation the testimony showed a complicated, compound, comminuted fracture of the left leg between the knee and the ankle, a resulting hernia, and, on the plaintiff's theory, that one of his testicles had been driven by the accident up into his abdomen and remained there at the point of the hernia. The medical testimony showed that nothing short of an operation would put the dislocated testicle in the place nature designed for it; but there was no testimony tending to show that an operation was either necessary or advisable to protect or restore the integrity of its normal function or that its present condition was dangerous to health, inconvenient, or tended to make it functus officio. It was therefore held that an instruction on the reasonable probability or necessity of future medical service to replace it, as an element of damages, was unwarranted. The defendant's argument was that the accident did not (and could not) cause the dislocation. It rested this argument on the fact that the doctors testified they never read of or saw an incident of the kind; that the size of the usual canal excluded the idea that the testicle could be driven by force from nature's sack up and into the abdomen through this canal. The medical theory was that the progress of the testicle down had merely been arrested in the fetal stage and that it had never been in place. This testimony was negatived by the plaintiff's mother, and other witnesses testified that before the accident the plaintiff was normal in this particular and abnormal ever afterward. The court held the question to be one of fact for the jury, which found for the plaintiff.—Sang vs. St. Louis, Missouri Supreme Court, 171 S. W. 347.

STUDIES ON HUMAN GROWTH.

There is no topic in human physiology more fascinating than that dealing with the laws of growth, a topic to which increasing attention has been paid within recent years. In view of the ease with which simple mathematical methods can be applied in the study of this subject, it is surprising that the laws of growth were not definitely formulated a long time ago. Probably this very ease has not furnished an adequate stimulus for scientific investigation.

In a study of the pre- and postnatal growth of infants, T. Brailsford Robertson (*American Journal of Physiology*, April 1, 1915) first calls attention to the varying rapidity of growth which first takes place relatively slowly, then more rapidly, and then again more slowly, as may be represented by an S-shaped curve. In fact, two or more curves of this nature may be superimposed upon one another during the entire period of growth, each curve characterizing what the author terms a growth-cycle. The extrauterine growth of the human being comprises two growth-cycles and a portion of a third which begins during intrauterine life. Read has shown that the intrauterine life of the guinea-pig consists of one whole growth-cycle and a portion of a second, which continues after birth. The junction of the two cycles represents a critical period during which death and premature delivery are more apt to occur than at any other time. Robertson sought to determine whether a similar critical period occurs in the intrauterine growth of the human infant, using for this purpose the statistical records of a maternity hospital in Adelaide, South Australia.

It was found that there is apparently no indication of more than one growth-cycle during the intrauterine growth of man subsequent to implantation of the ovum. This cycle is interrupted by birth when it is not yet half completed and culminates towards the end of the first year of postnatal life. Its magnitude is equal in the male and female, but it is of slower development in the latter. Robertson states that there are probably four and certainly not less than three growth-cycles in the normal development of man, as follows: (1) A very brief, so-called "autostatic" cycle probably preceding implantation of the ovum, during which the growth is chiefly nuclear and is accompanied by a decrease of phospholipenes in the tissues. (2) An "autokinetic" cycle lasting from nearly the beginning of development until nearly the end of the first year of extrauterine life and accompanied by the production of tissues unusually rich in phospholipenes. This period of growth acquires its maximum velocity at 1.66 months in males and 2.47 months in females. (3) The next cycle starts during or close to the completion of the first year of extrauterine growth and partially fuses with the suceeding cycle. It attains its maximum rate at about 5.5 years in both sexes, and since it is accompanied by a diminution of the phospholipenes in the tissues it is characterized as belonging to the "autostatic" type. (4) The final cycle, with a maximum velocity at about 14.5 years in females and 16.5 years in males, culminates in the attainment of adult weight and is believed to be "autokinetic."

There is no evidence of any critical period in human intrauterine development at which maldevelopment and premature delivery are more liable to occur, in infants born by normal mothers, than at any other period in intrauterine life. On the other hand, there is such a critical period in the latter half of the first year of extrauterine life, during which period an exceptional proportion of infants are liable to be subnormal in weight, and manifest an increased susceptibility to certain zymotic diseases. The suggestion is made that this critical period is probably attributable to a certain difficulty with which the two growth cycles which meet at this period "link" up with each other. Apparently the change from one growth cycle to a succeeding one is coincident with profound changes in metabolism that may for the time disturb the vital equilibrium.

THE LOCAL ACTION OF LEAD.

Although lead poisoning appears in several forms it is such a familiar condition that it is usually fairly readily recognized, the diagnosis often being made by the patient or his friends. An acute general intoxication does not seem to exist, the so-called acute cases being in reality chronic cases in which the patient is especially susceptible and suffers from more severe symptoms. The lesions which have been found in lead poisoning have been of a chronic nature, have progressed to sclerosis, and therefore the method of their production has not been determined.

In a recent paper (*Jour. Med. Research*, 1915, xxxii, 271) McJunkin details the results of some experimental work which helps to elucidate this point. Lead like many other metals forms an insoluble compound with protein so that the lead is precipitated on gaining access to the cells or fluids of the body. McJunkin gave lead by mouth to more than seventy-five dogs, monkeys, rats, guinea-pigs, and rabbits, and made post-mortem examinations after from six hours to 236 days. The results were quite uniform, the animals showing lesions in the gastrointestinal mucous membrane, the liver, and the blood. He showed that the lesions in the gastrointestinal tract consist in a necrosis of the mucosa which is rapidly repaired, in one case at least, within seventy-two hours. The epithelium grows

over the surface, leaving the lead in place beneath it. Granules of lead are shown taken up by the endothelial leucocytes in the mucosa and it eventually is removed entirely in this manner. After about three days it becomes difficult to demonstrate the lead within the leucocytes and at about this time hyaline basophilic granules appear in the cells of the liver and the red cells of the blood. By treatment with an alkaline sulphide solution he was able to show that these granules contained lead.

Since it seems improbable that the particles of precipitated lead work their way into the liver cells from the leucocytes, the author advances the theory that in the leucocytes the insoluble lead albuminate is changed into a compound, probably a lead alkyl, which is soluble in albuminous fluids and in which form it passes into the blood and liver producing basophilic granulation. He is unable to explain the absence of lesions in other organs. There is a question of the necessity of advancing such an hypothesis. It is quite possible that lead is not precipitated *absolutely* quantitatively by albuminous fluids, and exceedingly small quantities of the metal are sufficient to produce poisoning provided that it be administered over a long period of time. The apparent demonstration that by means of the leucocytes the poison is distributed through the body is interesting. The process is probably analogous to that which takes place in other conditions. So far as we are aware this is the first time that it has been shown that the basophilic granules in the red cells in lead poisoning contain metallic lead or a compound of it.

A NATIONAL MEDICAL LICENSING BOARD.

For many years, from the very beginning, in fact, of the movement for State medical examination and licensure, the inconveniences and evils of a State board have been recognized, but have been thought to be inseparable from the system itself. Our peculiar form of government, with its confederation of forty-eight largely independent republics, makes uniformity of laws dealing with domestic matters practically impossible. A man may be legally crazy in one State and sane in another; he may be lawfully married in one and an adulterer or a bigamist in another, and, if engaged in the practice of medicine, he may be an honorable physician in one and, in the eyes of the law, a quack in another. Many attempts have been made to induce the States to adopt uniform qualifications and to inaugurate a policy of genuine reciprocity, so that a legal practitioner in one State may be admitted to practice without further examination in another. But all such attempts have failed, of necessity, and all suggestions of a federal regulation have been silenced by the fact of the unconstitutionality of any such measures.

The attempt is now about to be made, however, to establish a system of national licensure by grace of the States. In his presidential address before the American Medical Association, meeting in San Francisco this week, Dr. Rodman described the plan which is to be inaugurated in the autumn. According to this, the details of which are given in our report of the meeting in another column, a national board of medical examiners, of which the surgeons general of the U. S. Army, Navy, and Public Health Service, with representatives of the Confederation of State Boards of Examiners, the Association of American Medical Colleges, the American College of Surgeons, and the American Medical Association, will be members, will meet in Washington in October, to examine such candidates as may present themselves. There is no doubt that the man who succeeds in passing this examination will be fit to practise medicine in any State of the Union, but whether or not he will be allowed to do so will depend upon the will of the several State boards. Some of these are forbidden by law to admit anyone to practice without an examination, and in such cases a change in the law will be necessary if the plan of a national licensure is to become universally effective; in other States the boards have discretionary powers to grant licenses to practitioners from other States or countries without examination, and these, if they will, can at once give standing to the licentiates of the national board. In Canada there is a national board of examiners, as well as provincial boards, and the latter all accept the examination of the national board and recognize its licentiates. That such unanimity will prevail at once in the case of all our States is hardly to be expected, but even if only twenty of the largest and most populous of them agree to the plan, the success of national licensure will be assured. No one who stops to consider the many disadvantages of the diversity of our State medical license laws can help wishing this project every measure of success.

HEART DISEASES IN THE GERMAN ARMY.

The so-called "cadet heart" has long been known, at least by reputation, to American physicians, and it is self-evident that in warfare heart strain due to forced marches and other physical hardships should be in evidence just as in civil life. It cannot be justly claimed, however, that the strain on the soldier's heart is so persistent as that in many peaceful occupations; while the clothing of the rank and file in actual warfare is quite unlike the heavy, rigid, and oppressive uniform of cadets on parade.

In a recent session of the Hamburg Medical Society (*Münchener medizinische Wochenchrift*, April 13) Reiche announces the results of physical examination of a large number of soldiers. The proportion of those with positive cardiac finds is not stated, but three distinct types are given. No comment is made of the fact that some of the troops had cardiac lesions before the war. The second class of lesions developed during the war. These include acute, at times fatal, dilatation, but also lessening of the heart shadow. Dilatation affects the right heart most frequently. As a rule these affections of the myocardium recover readily under treatment and rest. Digitalis and strophanthus are indicated. In a third group the state of the heart is a functional one, secondary to one or several cooperating factors, as tuberculosis, Graves's disease, alcoholism, nicotism, and essential neurasthenia. It

is very difficult to discriminate between the neurogenic and myogenic types, although in the former there is no alteration in the size of the shadow. In the purely functional type the patient has a neuropathic substratum, as shown by a rapid, irregular pulse. There is usually a systolic murmur over the pulmonary artery which nearly or quite vanishes on inspiration. The author ascribes it to friction of the pericardium against the wall of the chest. Pressure points are discovered over the latter and slight compression of the apex with the finger will cause alterations in the pulse. Digitalis is contraindicated, while bromides are useful. The word "heart disease" should never be uttered in the patient's presence, else he may develop a fixed idea of a serious condition.

Tetanus Neonatorum.

Within a very recent period several cases of this supposedly incurable condition have responded successfully to treatment, which consisted of or included the use of magnesium sulphate. In the *Deutsche medizinische Wochenschrift* for April 22, we find a belated account of a discussion on this affection which took place just before the breaking out of the war. Czerny laid stress upon the fact that tetanus bacilli are not found in umbilical infection of the newly born, but was set right on this point by Baginsky who remarked that Kitasato had found the bacilli in pus from the navel. Finkelstein stated that trismus nascentium so-called was by no means always a tetanus and was often due to skull traumatisms and encephalitis. Further the geographical pathology bas been neglected. Tetanus (infectious) of the newly born is rare in Germany, but common in Roumania. Negative bacillary finds signify but little in the presence of positive finds of other sorts. Czerny in alluding to cases in the tropics adds that umbilical antisepsis has not prevented tetanus. He has been on the hunt for tetanus germs in the navel for twenty-two years and has yet to find one. Tetanus of the newly born is not due to infection in the ordinary sense but belongs under the nervous affections. The consensus of opinion appeared to be that this question should be left open. The influence of magnesium in such a neurosis could be readily understood. None of those who discussed the paper threw any light on the alleged neurotic tetanus of the newly born, with reference to its intimate nature, and they left undetermined the question of its bacterial origin.

Animal Venoms and Venomous Animals.

Many singular data come to light as a result of the study of serpent venoms. The sting of the Bosnian sand viper causes an ulcer which may become cancerous. Since venoms proceed from glands which are analogous to human salivary glands it is not surprising to learn that the venomous secretion belongs to the normal digestive fluids. To diminish the number of venomous snakes in a locality the mice, rats, etc., upon which they feed may be exterminated while animals which prey on snakes may be colonized—the mongoose, hedgehog, hawks, storks, pigs, and even other snakes (constrictors). At the last meeting of the Breslau Medical Society before the war outbreak (*Deutsche medizinische Wochenschrift*, April 15), Professor Küttner, the well-known surgeon, cited the above and many other data. Under the old and present nomenclature the lesions due to animal poisons are regarded as purely surgical subjects, because surgical intervention and wound treatment are alike demanded. The advent of snake antisera, new chemical remedies, etc., does not lessen the surgical predominance of treatment. Küttner states that cupping is of no use, while among chemicals only some of the hypochlorites have any value (potassium, calcium). Constriction of a limb is a valuable resource. Horse serum slightly impregnated with snake venom and Calmette's sera have given some good results, even in advanced cases.

News of the Week.

Committee of American Physicians for the Aid of the Belgian Profession.—Dr. F. F. Simpson, 7048 Jenkins Arcade Building, Pittsburgh, Pa., reports the receipt of the following contributions during the week ending June 19, 1915:

Dr. L. O. Tarleton, 1st Lieut., U. S. A., Manila, P. I.	$5.00
Norwich Medical Association, Norwich, Conn.	25.00
Westmoreland County Medical Soc., Mount Pleasant, Pa.	25.00
Elmira Academy of Medicine, Elmira, N. Y.	50.00
Dr. Angus McLean, Detroit, Mich.	30.00
Receipts for the week ending, June 19th	$135.00
Previously reported receipts	7,312.00
Total receipts	$7,447.00
Previously reported disbursements:	
1,625 Standard boxes of food at $2.20	$3,575.00
1,274 Standard boxes of food at $2.30	2,930.20
353 Standard boxes of food at $2.28	804.84
Total disbursements	7,310.04
Balance	$136.96

The Second Harvard Surgical Unit.—It was announced in the *Boston Medical and Surgical Journal* of last week that the second Harvard surgical unit was to sail from New York on June 22, aboard the steamer *Noordam* for Falmouth, Eng., for six months' service in British or French hospitals. The expedition consists of 32 surgeons and 75 nurses, the majority of whom have volunteered for the entire period of service.

Summer Courses in Public Health.—The New York State Public Health Council has sent a letter to all health officers urging that they take advantage of special courses of study in public health, to be given this summer by Cornell University, Syracuse University, the University of Buffalo, and New York University.

Pasteurized Milk Stations.—Ten additional pasteurized milk depots were opened last week by Nathan Straus. In addition to the supplying of modified and pasteurized milk in nursing bottles, ready to be given to the babies, the summer work includes the serving of a glass of pasteurized milk for one cent.

Heavy Sentence for an Illegal Practitioner.—A man named Schierson was sentenced last week to six months in the penitentiary for maintaining a "medical museum" in this city. He pleaded guilty and received the heaviest prison sentence that has been meted out by the court to any such practitioners, without the option of a fine.

Another Degree for Dr. Gorgas.—The honorary degree of Doctor of Laws was conferred upon Surgeon-General William C. Gorgas, of the United States Army, on June 15 by Georgetown University, in recognition of his work in the Panama Canal Zone.

Dr. Edward W. Ryan, chief of the American Red Cross in Belgrade, has been decorated by both the

Servian and French Governments for his work in the hospitals where typhus fever has been raging. France has made him chevalier of the Legion of Honor, the official order of the French Republic. Crown Prince Alexander himself bestowed on Dr. Ryan the Servian decoration of the Order of St. Sava. At the same time the Crown Prince expressed his appreciation of "this worthy and noble representative of the great western republic." Dr. Ryan is recovering from typhus, which he contracted while caring for the Servian patients.

Kansas State Board.—Twenty-two candidates passed the Kansas State medical examination in June and were admitted to practice in that State. At the close of the three-day session of the board on June 10 Dr. Anderson was reelected president and Dr. H. A. Dykes was reelected secretary. The other members of the board are: Dr. L. A. Ryder, Topeka; Dr. Albert S. Ross, Sabetha; Dr. F. D. Hatfield, Olathe; Dr. George M. Gray, Kansas City; Dr. C. W. Jones, Olathe.

Dr. Richard Strong who, with a party of surgeons and nurses from Serbia, arrived at the Piræus on June 17 aboard Sir Thomas Lipton's yacht *Erin*, was called by the Queen to see in consultation King Constantin, who has been suffering from empyema and has recently had to undergo an Estlander operation.

A Joint Meeting of the Medical Societies of the Counties of Allegany, Genesee, Livingston, and Wyoming (N. Y.) will be held at Letchwork Park, Portage Falls, on July 15. The members of the County Societies of Western New York other than those mentioned above are invited to be present. Drs. L. F. Bishop and W. S. Bainbridge of New York City will present papers. Letchworth Park is one of Nature's most beautiful spots in western New York and there will no doubt be a large attendance at this meeting.

The Rhode Island State Board of Health, at a meeting held on June 10, elected officers as follows: *President,* Dr. Alexander B. Briggs of Ashaway; *Vice-President,* Dr. Rufus E. Darrah of Newport; *Secretary,* Dr. Gardner T. Swarts.

The Missouri State Medical Association, at its annual meeting in May, elected Dr. C. R. Woodson of St. Joseph president. Soon thereafter there appeared in one or more of the St. Joseph newspapers the physician's professional card, giving his name and office address followed by the legend "Nervous Diseases." For this offense he was deposed by the judicial council of the association and Dr. C. B. Clapp of Moberly was appointed in his place. Dr. Clapp declined to serve and Dr. Woodson brought suit against the council on the ground that its action was illegal. Then the advertisement was withdrawn. The council admitted that its action was illegal because of the lack of a quorum and announced that Dr. Woodson had made reparation by acknowledging the wrong of advertising, the suit was discontinued, the unanimously elected president is again in office, and peace reigns.

New York's Death Rate.—During the week ending June 12, 1479 deaths were reported in this city as against 1365 for the corresponding week of last year, an actual increase of 114 deaths. If, however, the increase in the population is considered there were only 60 more deaths. The death rate for the week was 13.29 as against 12.75 for the corresponding week of last year.

Opposition to a New Health Bill in Wisconsin.—The Milwaukee County Medical Society, at its June meeting, adopted a resolution opposing certain provisions in the "public welfare bill," now before the State Legislature, which abolishes the State Board of Health, the State Board of Control, the State oil inspector, and the State Dairy Commission and substitutes a new board to be called the "Wisconsin State Board of Public Welfare," and to consist of a farmer, a woman, a physician, a dairyman, and a business man, each to draw a salary of $3,500 a year.

The Decreasing Tuberculous Mortality.—At the meeting of the National Association for the Study and Prevention of Tuberculosis in Seattle last week the president, Dr. George M. Kober of Washington, D. C., said that tuberculosis in all its forms carried off during the year 1913 over 143,000 persons in the United States, which signifies the presence of approximately 1,430,000 consumptives, with an economic loss of at least $214,500,000 per annum. "Nevertheless," he said, "there is certainly hope when we consider that the death rate from this disease has been reduced from 326 per 100,000 population in 1880 to 146.6 in 1913, which means that if the former rate had been continued the number of deaths from this cause would have been 322,027 instead of 143,000 in 1913, equivalent to a saving of 179,027 during one year." The membership of the association now numbers more than 2400.

Cancer Study Meetings in Vermont.—Several cancer study meetings were held recently in various districts of Vermont under the auspices of the Vermont State Medical Society. The first of these meetings took place at Rutland on June 8. Dr. W. Seaman Bainbridge of New York held a consulting and operating clinic at the Rutland Hospital. At Shrine Hall Dr. Charles Francis Dalton of Burlington discussed Vermont's cancer situation, Dr. Bainbridge of New York dealt with some practical phases of the cancer problem, and Dr. Jonathan Wainwright of Scranton, Pa., considered the field of the medical profession and the laity in the reduction of cancer mortality. In the evening at the Rutland High School Assembly Hall Drs. C. F. Dalton and Bainbridge discussed the cancer problem in relation to Vermont from other standpoints. On June 9 the meeting was at Burlington. Consulting and operating clinics were held at Mary Fletcher Hospital by Dr. Jonathan M. Wainwright, and Dr. Francis Carter Wood of New York, Dr. Wainwright, and Dr. C. F. Dalton, in the course of the day and in the evening discussed the cancer problem as regards Vermont. On June 10, at St. Johnsbury, a similar program was gone through and in addition Dr. Bainbridge gave a stereopticon cancer clinic. On June 11, at Montpelier, Drs. Wainwright, Dalton, and Bainbridge dealt with the question of cancer from various standpoints, and Dr. Bainbridge held a consulting and operating clinic at Heaton Hospital. Dr. James Hamilton, secretary of the Vermont State Society, chairman of the committee for the purpose of inaugurating a special campaign for the education of the profession and laity with regard to the cancer problem, was responsible for the organization of the several meetings.

Medical Society Elections.—THE AMERICAN PEDIATRIC SOCIETY, at the annual meeting held in Lakewood, N. J., May 24-26, 1915, elected the following officers: *President,* Dr. Rowland G. Freeman of New York; *Vice-President,* Dr. J. C. Gittings of Philadelphia; *Secretary,* Dr. Samuel S.

Adams of Washington, D. C.; *Treasurer*, Dr. Charles Hunter Dunn of Boston; *Editor and Recorder*, Dr. L. E. La Fetra of New York.

The American Surgical Association at its annual meeting of this association, held in Rochester, Minn., June 9-11, elected the following officers: *President*, Dr. Robert G. Leconte, Philadelphia; *Vice-Presidents*, Drs. Charles L. Gibson, New York, and Archibald MacLaren, St. Paul; *Secretary*, Dr. John H. Gibbon, Philadelphia; *Recorder*, Dr. John Binnie, Kansas City; *Treasurer*, Dr. Charles H. Peck, New York. Among the papers presented was one by Dr. J. Ewing Mears of Philadelphia, one of only two living original members of the association, on "The Great Names in American Surgery, Pioneers, and Founders." The 1916 meeting of the association will be in Washington in May.

The Rhode Island Medical Society held its annual meeting in Providence on June 4, and elected the following officers: *President*, Dr. Frank L. Day; *First Vice-President*, Dr. E. D. Chesebro; *Second Vice-President*, Dr. John Champlin; *Secretary*, Dr. Jay Perkins; *Treasurer*, Dr. Winthrop A. Risk.

The Maine Medical Society in annual session, held at Poland Spring in June, elected these officers: *President*, Dr. E. E. Holt of Portland; *First Vice-President*, Dr. H. B. Mason of Calais; *Second Vice-President*, Dr. Harry A. Snow of Milo; *Secretary-Treasurer*, Dr. John E. Thompson of Bangor. The 1916 meeting will be held at Portland.

The Connecticut State Medical Society, at its annual meeting held in Hartford in May, elected the following officers: *President*, Dr. Max Mailhouse of New Haven; *Vice-Presidents*, Drs. Charles B. Graves of New London, and Cushman A. Sears of Portland; *Secretary*, Dr. Melvin McR. Scarborough of New Haven; *Treasurer*, Dr. Joseph H. Townsend of New Haven; *Committee on Scientific Work*, Drs. Wilder Tileson of New Haven, and Frank W. Stevens of Bridgeport; *Committee on Medical Examinations and Education*, Dr. Charles A. Tuttle of New Haven; *Committee on Public Policy and Legislation*, Drs. Everett J. McKnight of Hartford, Charles J. Foote of New Haven, Rush M. Kimball of Norwich, W. H. Donaldson of Fairfield, George M. Burroughs of Danielson, Ralph S. Goodwin of Thomaston, Frank K. Hallock of Cromwell, and Eli P. Flint of Rockville; *Committee on Honorary Members and Degrees*, Drs. William H. Carmalt of New Haven, D. Chester Brown of Danbury, and Seldon B. Overlock of Pomfret; *Delegate to American Medical Association*, Dr. Everett J. McKnight of Hartford. Bridgeport was selected as the place for the annual meeting in 1916.

The New Hampshire State Medical Society, at its annual meeting held in Concord in May, elected the following officers: *President*, Edgar O. Crossman, Lisbon; *Vice-President*, Emdon Fritz, Manchester; *Secretary*, D. E. Sullivan, Concord; *Treasurer*, D. M. Currier, Newport; *Trustee*, H. L. Smith, Nashua; *Merrimack County Councilor*, R. J. Graves, Concord; *Hillsborough County Councilor*, F. J. Kittridge, Nashua; *Delegate to American Medical Association*, C. W. Hanaford, Portsmouth; *Alternate*, R. J. Graves, Concord.

Connecticut River Medical Association.—At the annual meeting of this association, held with the Windham County Medical Society at Bellows Falls on May 11, the following officers were elected: *President*, Dr. W. P. Craig of Walpole; *Vice-President*, Dr. L. H. Bugbee of Putney; *Secretary-Treasurer*, Dr. J. Sutcliffe Hill of Bellows Falls.

The Windham County (Conn.) Medical Society, at its annual meeting held with the Connecticut River Medical Association at Bellows Falls on May 11, elected the following officers: *President*, Dr. W. F. Hazelton of Bellows Falls; *Vice-President*, Dr. F. L. Osgood of Saxtons River; *Secretary-Treasurer*, Dr. G. R. Anderson of Brattleboro.

The Manchester (N. H.) Medical Association, at a meeting held on June 11, elected the following officers: *President*, Dr. Daniel C. Norton; *Vice-President*, Dr. Charles E. Flanders; *Secretary and Treasurer*, Dr. M. P. Badger; *Board of Censors*, Drs. M. P. Towle, J. C. O'Connor, M. P. Badger, W. H. Lyons, and J. E. Larochelle.

The La Salle County (Ills.) Medical Society, at its sixty-second annual meeting held in Ottawa on April 27, elected the following officers: *President*, R. C. Fullenweiden, La Salle; *Vice-President*, A. J. Weirick, Marseilles; *Secretary-Treasurer*, E. E. Perisho, Streator; *Board of Censors*, W. E. Smith, Grand Ridge; J. S. Geen, Utica; W. W. Greaves, Streator; *Delegate*, W. O. Ensign, Rutland; *Alternate*, E. W. Weis, Ottawa; *Medicolegal Committee*, E. W. Weis, Ottawa.

The Fifth District (S. C.) Medical Society, at its annual meeting held in Chester on May 21, elected the following officers: *President*, Dr. E. W. Pressley of Clover; *Vice-Presidents*, Dr. Samuel Lindsay of Winnsboro, and Dr. R. T. Ferguson of Gaffney; *Secretary and Treasurer*, Dr. George A. Hennies of Chester.

The Connecticut Homeopathic Medical Society, at its annual meeting held in New Haven on May 18, elected the following officers: *President*, Dr. George E. Evans, Branford; *Vice-President*, Dr. Eugene L. Bestor; *Treasurer*, Dr. Henry B. Sage of New Haven; *Secretary*, Dr. Richard Blackmore of Farmington.

The Worcester (Mass.) North District Medical Society, at its annual meeting in Fitchburg, April 27, elected the following officers: *President*, Dr. J. B. Donnelly of Gardner; *Vice-President*, Dr. A. A. Wheeler of Leominster; *Secretary*, Dr. Curtis H. Jennings of Fitchburg; *Treasurer*, Dr. Frederick H. Thompson, Jr., of Fitchburg; *Commissioner of Trials*, Dr. Frederick H. Thompson, Sr., of Fitchburg; *Councilors*, Dr. Charles E. Bigelow of Leominster, Dr. E. A. Sawyer of Gardner, Dr. Atherton P. Mason, and Dr. John W. Stimson of Fitchburg; *Nominating Committee*, Dr. E. A. Sawyer of Gardner; *Alternate*, Dr. A. P. Mason of Fitchburg; *Censors*, Dr. J. W. Stimson, Dr. A. P. Lowell of Fitchburg, Dr. A. A. Wheeler, of Leominster, Dr. W. F. Robie of Baldwinville, and Dr. B. H. Hopkins of Ayer; *Librarian*, Dr. A. P. Mason of Fitchburg; *Library Committee*, Dr. A. F. Lowell of Gardner, and Drs. L. F. Baker and F. H. Thompson, Jr., of Fitchburg.

The Berkshire District (Mass.) Medical Society, at its annual meeting in Pittsfield, April 29, elected the following officers: *President*, Dr. E. G. Howard of Pittsfield; *Vice-President*, Dr. A. K. Boom of Adams; *Secretary*, Dr. O. L. Bartlett of Pittsfield; *Treasurer*, Dr. J. D. Howe of Pittsfield; *Commissioner on Trials*, Dr. H. B. Holmes of Adams; *Councilor for State Nominating Committee*, Dr. L. A. Jones of North Adams; *Alternate*, Dr. J. H. Riley of North Adams; *Councilors*, Drs. E. H. Howard and Henry Colt of Pittsfield, L. A.

Jones and J. H. Riley of North Adams, and E. A. Kennedy of Great Barrington; *Supervising Censor*, Dr. Henry Colt of Pittsfield; *Censors*, Dr. William Gavin of Blackinton, Dr. George P. Hunt of Pittsfield, Dr. H. E. Stockwell of Stockbridge, and Dr. A. C. England of Pittsfield; *Nominating Committee*, Dr. E. W. Markham of Lee, Dr. B. W. Paddock of Pittsfield, and the secretary, ex-officio; *Committee of Arrangements*, Drs. A. P. Merrill and T. P. Hennelly of Pittsfield and the secretary, ex-officio.

Obituary Notes.—Dr. ALFRED MITCHELL of Brunswick, Me., emeritus professor of internal medicine in the Medical School of Maine, Portland, and dean of the school for many years, a graduate of the College of Physicians and Surgeons, New York, in 1865, and a member of the American Medical Association, the Maine Medical Association, of which he was at one time president, and the Cumberland County Medical Society, died suddenly on June 13, aged 78 years.

Dr. JOHN H. MCCOLLOM of Boston, emeritus professor of contagious diseases in the Harvard University Medical School, and until recently superintendent of the Boston City Hospital, a graduate of the Harvard University Medical School in 1869, a veteran of the Civil War, and a member of the American Medical Association, the Massachusetts Medical Society, and the American Association of Pathologists and Bacteriologists, died at his home, after a long illness, on June 14, aged 72 years.

Dr. JOB CORBIN of Brooklyn, N. Y., a graduate of the University of Vermont, College of Medicine, Burlington, in 1859, a surgeon in the United States Navy during the Civil War, died at his home on June 14, aged 80 years.

Dr. LEON OCTAVE MONORY of New York, a graduate of the University of Paris, France, in 1873, formerly a surgeon in the French Army, and a veteran of the Franco-Prussian War, died at his home on June 16, aged 69 years.

Dr. ROBERT M. LANGDON of Englewood Cliffs, N. J., a graduate of the University of Berlin, Germany, in 1880, of the Illinois Medical College, Chicago, in 1897, and of the Long Island College Hospital, Brooklyn, in 1898, died at his home on June 17, aged 55 years.

Dr. JOHN D. MILLER of Batesville, Miss., a graduate of the Louisville, Ky., Medical College in 1903, and a member of the Mississippi State Medical Association and the Panola County Medical Society, was killed in an automobile accident on June 1, aged 37 years.

Dr. WILLIAM WABASH KNEALE of Anderson, Ind., a graduate of the University of Virginia, Department of Medicine, Charlottesville, in 1889, and a member of the Indiana State Medical Association and the Madison County Medical Society, died suddenly, from apoplexy, on June 9, aged 54 years.

Dr. JOSEPH PREVETT of Boston died on June 6 from tuberculosis, after a long illness, aged 37 years.

Dr. JOHN M. BRIGGS of Woodburn, Ky., a graduate of the Medical Department, University of Nashville, Tenn., in 1859, and a member of the Kentucky State Medical Association and the Warren County Medical Society, died at his home, after several weeks' illness, on June 7, aged 78 years.

Dr. ROBERT W. LONG of Indianapolis, Ind., a graduate of the Bellevue Hospital Medical College, New York, in 1869, and the founder of the Robert W. Long Hospital of Indiana University, died at his home on June 18, aged 72 years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

GENERAL MEDICAL COUNCIL—PRESIDENT'S ADDRESS—SHORTAGE OF MEDICAL MEN THROUGH THE WAR—LISTER INSTITUTE—CLEANLINESS IN DERMATOLOGY—AN ANTI-FLY EXHIBITION.

LONDON, June 5, 1915.

THE General Medical Council's meeting for this year opened on Tuesday and, as in so many other institutions, its proceedings have been largely dominated by the war. The president, Sir Donald MacAlister, in his address dwelt on the efforts that have been necessary to meet the calls of the army and navy for medical aid. The services of qualified men and women at home and in the colonies have been freely offered and accepted. Senior students enrolled in the ranks have been recalled by the War Office and directed to complete their curriculum so as to qualify for the R. A. M. C. Foreign doctors of medicine have been accepted on obtaining British qualifications. The casualties have been heavy, but confidence is felt that the schools and corporations will be able to replace the fallen and yet maintain in this emergency the standards of teaching and testing which are essential to efficiency. Although there were 1,000 fewer students at the end of 1914 than of 1913 the recall of the seniors who had enlisted must tend to meet the supply. There will probably be a falling off for the next few years of those taking their diplomas. From Canada many efficient surgeons are coming, some slight obstacles at first having been removed.

The Lister Institute's twenty-first annual meeting was held on the 12th inst. The report mentioned that on the declaration of war the services of the staff were placed at the disposal of the army medical department, with a list of volunteers for foreign service and an offer to supply serums and vaccines at cost price. Grateful acceptance was expressed and a full supply forthwith requested. The consequence was considerable pressure on the laboratories cheerfully met by all concerned who were also assisted by other bacteriologists and institutions.

One aspect of Listerism was the subject of an interesting discussion at the new Dermatological Society. It was started by Dr. Eddowes, president, with remarks on "Clean Dermatology," who said our difficulty in this specialty is to obtain asepsis, and if we can do this the case is cured. But mild and strong remedies alike may fail if unskillfully employed. He cited a case of impetigo spread all over a child's face, who had had applied too weak a lotion for the initial small lesions. But too strong remedies will inflame the skin. He mentioned also some cases pointed out to him as very rebellious with a request for a suggestion. He recommended cleaning with spirits and at once covering with a paste—the same paste has been used, but the cleaning first was the point. That insured success.

Dr. Walsh said in one class the organism was on the surface and could be dealt with, but some skin troubles were symptomatic of toxins in the blood or defective excretory functions. Identification of the organism and its lurking place in the body would lead to effectual treatment.

Mr. Dennis Vinrace claimed for the late Dr.

McLaren of Chelsea similar honor to that accorded to Lister. Dr. McLaren, he held, stood towards medicine as Lister did to surgery. Though largely unrecognized during his life he hoped to see a statue erected to the memory of McLaren. He indorsed the statements made as to the necessity of cleanliness, but the discussion of it must not indicate any want of it among dermatologists. He was always careful to clean off stale ointments as he went along. Sometimes he alternated ointments and lotions to insure getting rid of one dressing when another was applied.

The discussion was continued by several other members with a general consensus of opinion that though dermatologists did not neglect cleanliness as a remedy it was impossible to insist too much on its value.

A campaign against insects has been opened by the Zoological Society in the form of an anti-fly exhibition. The chief object is to show the public that the housefly is by no means a mere nuisance but too often the carrier of disease and therefore a danger to health against which continual war should be waged. If we cannot exterminate it we may determine to drive it from our habitations and immediate surroundings. Feeding on putrid organic matter it frequents accumulations of filth, particles of which cling to it, are carried away and drop off at a distance—often enough on human food or the vehicles containing it. Among the disgusting things in which they revel are the dejecta of animals and men to which they can get access, and here we can trace a direct way in which diseases may be propagated, *e.g.* their wings and feet may take up the typhoid poison as they settle a moment on a patient's excreta, and thus they become distributors of the infection. Possibly this may occur more frequently than is suspected. In the exhibition mentioned above there is a large scale picture of a fly, its hairy feet prominently displaying how easily all this may occur and more, too. Not only do they feed on offal, they breed in it, and prolific breeders they are. At the exhibition there are specimens of their eggs in many kinds of refuse just as they were laid. The germs and the processes by which they are spread form microscopic objects of interest among the exhibits. The importance of these is that knowledge of them lies at the base of every reasonable weapon in our war against the pest.

As to prevention, there are traps that can be examined by people who like to amuse themselves with such things. The simplest seems to be one sent from your side, Minnesota, I think. Poison is more efficient and perhaps less trouble. But there is always danger connected with it, especially where children are about. Our most effectual weapon against these and other insect pests is crude mineral oil, well known to many but in some localities still unknown. Large quantities are being supplied to our troops in the war. An emulsion of 5½ to 3 of soap with a little water is a good form for many purposes, though in others the crude oil can be used undiluted in all sorts of ways. There are preparations at the exhibition with a purified oil, but none are more deadly insecticides than the crude oil.

Cholesterin Therapy in Pernicious Anemia.—C. Cantieri bases this mode of treatment upon the supposition that pernicious anemia is the result of a toxin which combines with and is neutralized by cholesterin.—*Rivista Critica di Clinica Medica.*

2. Bacteria in the Etiology of Diarrhea.—A. I. Kendall, on the basis of his experience with the summer diarrheas in Boston, suggests that there may be a tendency for certain organisms to be dominant at one or another year. In 1910 the dysentery bacillus was by far the most frequent organism found in severe diarrheas of children. In 1911 but few dysentery cases were found and the streptococcus became dominant. In 1912 neither dysentery bacilli nor the streptococcus were prominent, but the gas bacillus appeared to be the more important factor. And in 1913 dysentery, streptococcus, and gas bacillus cases were few in number and sporadic, while the capsulated bacillus appeared to be the most common etiological factor in the diarrheas.

3. Clinical Use of the Water Meal.—A. E. Austin has employed this method as follows: The custom was to ask a patient to take a meal, the evening before, of meat, potato, bread, butter, rice, and raisins, and then come to the clinic the next morning fasting. There 350 c.c. of water were given the patient and the contents of the stomach removed twenty minutes later, the extreme limit at which it is claimed that the water given has left the stomach. The superficial advantages of this method were readily recognized; bread is not always available for the test breakfast, but water, of course, is. One can never rely on the time, if patients are allowed to take their bread at home and then come to the clinic; while, if taken in the clinic, a wait of 45 to 60 minutes is too long in a busy forenoon. Water, too, allows one to see readily whether there is any residue left from the Riegel meal. This method also avoids a second introduction of the tube, which is necessary if one first attempts to find food remnants in the fasting stomach, and then gives the ordinary test breakfast. Lactic acid, blood, and bile are also much more readily detected in the absence of a mass of partly digested food.

1. Tuberculosis and Contraception.—S. A. Knopf believes that where there is tuberculosis or any other serious transmissible disease in one or both of the parents, and there is danger that it may be transmitted to the offspring, it should be not only the right but the sacred duty of the physician to prevent the conception of any physically and mentally handicapped off-

spring destined to become a burden to the community. It is for this reason that the author entertains the hope that the New York penal code will be so modified that it will not be considered a criminal offense for the duly licensed physician to advise against conception when, in his judgment, this conception would be dangerous to the health of the mother or result in physically, mentally, or morally defective offspring.

2. **Developmental Reconstruction of the Colon.**—By J. M. Lynch and J. W. Draper. (See MEDICAL RECORD, May 29, 1915, page 919.)

3. **Chronic Intestinal Stasis.**—By G. R. Satterlee. (See MEDICAL RECORD, May 29, 1915, page 918.)

4. **Treatment of Erysipelas with Carbolic Acid and Alcohol.**—A. Judd details this method of treatment as follows: There is painted carefully with a swab of cotton upon an applicator the entire surface of the involved area, and extending about a half inch into the surrounding apparently healthy skin, 95 per cent. carbolic acid. This is left until the purplish color of the inflamed area is replaced by a pretty complete whitening of the skin. It is essential to the success of the procedure that we await this whitening before one proceeds to the next step. On the other hand, if one allows the whitening to proceed to a thorough blanching, one produces a distention of the epithelium, a slough of the skin, which, while it will not produce a scar, will prove painful to the patient, delay the result, and add nothing to the efficacy. When large areas are involved it is advisable that only a portion be painted at one time. The second step consists in going over the whitened area very thoroughly with a second swab saturated with alcohol. If this swabbing is done thoroughly the whitened area becomes once more pink, and the alcohol must be laid on until this is accomplished. After this one proceeds with other areas with the carbolic, neutralizing with alcohol, until the operation is complete at one sitting. It is essential to include half an inch of the apparently sound skin, as the bacteria of erysipelas are found beyond the apparently involved area. In some of the author's first cases he neglected this precaution, and found in twenty-four hours that, while he had completely controlled the initially inflamed area, a ring of newly inflamed tissue extended out in all directions beyond, much as an advancing ringworm extends. The method includes the painting of the hairy scalp, the eyelids, the mucous membrane of the alæ of the nose, and the nipple of the breast, if necessary. The author failed to note any evil result. There has been no toxic action of the carbolic in any case so far observed, although the urine is sometimes darkened and of characteristic odor. The temperature falls rapidly. In severe cases it is frequently necessary to support the patient with strychnine and whisky.

8. **Scopolamine - Morphine - Cocaine Anesthesia in Surgery.**—A. G. Brenizer cites the following as advantages of scopolamine-morphine anesthesia. If the injections are given an hour and a half before the operation the patient does not know when he is removed from the room and placed on the operating table; there is no fear. The patient is undisturbed by the injections of cocaine (the beginning of the operation) or by the induction of an inhalation anesthesia. When an inhalation anesthesia is used, the patient passes quietly under its influence without experiencing the usual unpleasant sensations of suffocation, sinking into space, etc. The breathing is quiet and smooth. There is little or no accumulation of mucus and saliva to obstruct breathing or dirty the field of operation in head and neck case. Vomiting is extremely rare. There may be a depressant action on the over-secreting thyroid gland through the effect of scopolamine, making this anesthesia especially favorable in goitre cases. The ill effects after operation, such as nausea, vomiting, and headache, are almost always absent. The pain in the wound and pains generally after operations, are not so great because the effects of the injections, in some degree, last for hours. Shock during and after the operation is largely done away with by dispelling first the fear of the pending operation and by reducing the force of the pain impulses generally. The injections of cocaine block the pain impulses locally. The insufficient local analgesia and muscular relaxation can be sufficiently overcome by injections of dilute cocaine along with large quantities of normal salt solution.

9. **Mucous Membrane in Fasting Stomach Contents.**—E. A. Aronson states that the diagnostic importance of the finding of mucosa in the stomach contents is purely relative and not absolute. The microscopical examination may show normal tissue, or such lesions as a marked interstitial inflammation in cases which clinically may differ entirely from what is expected upon pathological examination. The greatest value of this finding from a diagnostic standpoint occurs in unsuspected or even suspected cases of gastric malignancy, in which no mass is palpable. Here the early diagnosis from the pathological laboratory would be appreciated, but unfortunately, when mucosa can be withdrawn through the tube, it occurs as a rule when the lesion is far advanced and the diagnosis has already been made by other means. The author emphasizes the fact that no ill effects such as hemorrhage or ulcer follow from the exfoliation of gastric mucous membrane, either by expression or aspiration through the stomach tube; that the sectioning and microscopical examination of these specimens is of undoubted aid in enabling one to arrive at a more exact diagnosis; that in cases of chronic subacid gastritis, the mucous membrane is decidedly more vulnerable than in other gastric lesions; and that the aspiration of stomach contents has every advantage over expression.

1. **The Rational Treatment of Hodgkin's Disease.**—J. L. Yates and C. H. Bunting tentatively define this disease as a noncontagious, infectious, granulomatous process due to the *Bacillus hodgkini*, a pleomorphic organism found almost constantly in pure culture in the pathological tissue of the disease. It is primarily localized at or about a port of entry, and has produced an analagous condition in monkeys by inoculation. The knowledge of the germ is not yet complete, though its casual relationship to the disease has been practically

demonstrated. The authors have proceeded on the plan of removing the primary source of infection, eliminating most rapidly the diseased tissues with its bacteria and toxins, and destroying the remaining bacteria by means of *x*-rays, hygiene, and vaccine therapy; by converting into fibrous tissue, by hygiene, and *x*-rays, such abnormal tissue as cannot be removed or undergo resolution; and, last, by continuing treatment until a clinical and roentgenologic examination and a normal blood picture show that the cure has been of at least a year's duration. Each of these measures is described and the results obtained are reviewed in detail. As regards vaccines, an ideal method of treatment is yet to be discovered. Supplementary treatment is necessary, as recrudescences are liable to occur. The general health should be carefully watched and routine periodical blood examinations be made. A cure can be considered as established only when there is no trace of the disease, including the blood conditions, for at least five years after the last manifestation.

3. The Landau Iodine Reaction in Syphilis.—A. W. Stillians concludes that no reliance can be placed on a positive Landau reaction, for this occurs in a large percentage of nonsyphilitics. A negative reaction is of no value in proving the absence of syphilis for a large proportion of syphilitics have a negative reaction. So far as the author's series of cases can show, no definite relation exists between syphilis and the Landau serum reaction.

5. Experimental Production of Herpes Zoster. — E. C. Rosenow and S. Oftedal have succeeded in producing herpes of the skin, tongue, or lips in rabbits and a number of other animals by intravenous injection of the bacteria in emulsions of extirpated tonsils of mixed cultures and pure cultures of streptococci obtained from tonsils or pyorrheal pockets and of streptococci in pure culture from the spinal fluid. In a number of the animals with skin herpes there were also herpetiform lesions of the viscera, and in these the ganglia of the vagus or sympathetic nerves were found to be hemorrhagic. The tendency of these organisms to localize in the ganglia is illustrated by the fact that herpes developed in six guinea-pigs following intraperitoneal injection. The streptococci isolated from the tonsils and other places after recovery, those cultivated on artificial media for a time, and those passed through a series of animals no longer show this peculiar property. The ganglion lesions consist chiefly in hemorrhages and round cell infiltration, usually marked outside and beneath the capsule and surrounding areolar tissue and along the sheath of the corresponding nerve. The blood vessels are commonly congested, and sometimes more or less filled with mononuclear and polynuclear leucocytes. Gram-staining diplococci and short chains are quite constant in the areas showing lesions about the ganglia, and cocci have been found in these lesions when absent in the blood and other tissues. Most of the cases studied were typical thoracic zoster.

13. Use of Kaolin in Removing Bacteria from Throat and Nose.—L. Hektoen and B. Rappaport note that kaolin is used in immunological and other investigations on account of its great adsorptive powers. The idea occurred to them that on account of this adsorptive power kaolin might be of use in removing bacteria from the nose and throat, especially in diphtheria carriers. They have found that, when properly applied, kaolin in the form of a dry powder removes not only diphtheria bacilli, but also practically all bacteria from the nose in the course of from three to four days. For this purpose the kaolin is blown into the nose six or seven times a day at two-hour intervals by means of a rubber bulb attached to a glass tube, the free end of which tapers a little. The insufflation is repeated several times at each treatment. The success of this treatment appears to depend largly on the free and thorough distribution of kaolin over the nasal surfaces. In cases of more or less obstruction of the nasal passages the removal of bacteria by kaolin insufflation is more difficult. In order to secure the most thorough application of kaolin to the mucous membrane of the throat, patients, if old enough, are instructed to swallow as slowly as possible one-third teaspoonful of kaolin four or five times an hour during the day. In the case of adults and older children who are anxious to get rid of diphtheria bacilli, this method, which has been selected after trial of several others, involves no special difficulty. In the case of small children it is more difficult to apply enough kaolin, and the plan of mixing the kaolin with sugar in the form of tablets is being considered. In a number of cases, in some of which there were a great many diphtheria bacilli in the throat, complete and apparently permanent removal has been accomplished by means of kaolin in the way described in from two to four days, the throat to a large extent being freed from all bacteria.

1. Arteriosclerosis. W. L. Blight.
2. Rheumatic Fever and Rheumatoid Arthritis: The Geographical Factor. J. T. Clarke.
3. A Case of Landry's Paralysis. J. S. B. Stopford.
4. On the Genesis of Constitutional Gastroptosis. J. J. Grace and W. Overend.
5. Some Points in the Circulatory System in Ankylostomiasis: A New Explanation for the Murmurs. Abd El Aziz Ismail.
6. Six Months with the Bearer Division of a Field Ambulance at the Front. S. J. A. H. Walshe.

1. Arteriosclerosis.—W. L. Blight states that there are four general causes of arteriosclerosis: (1) The normal wear and tear of life; (2) the acute infections; (3) the intoxications; and (4) those combinations of circumstances which keep the blood pressure high. The occupations most subject to the wear and tear of life are those of navvies, blacksmiths, porters, laborers, soldiers, and mountaineers, whose persistent use of muscles over prolonged periods to an extent sufficient to cause hypertrophy of the heart is a most potent factor in causing a heightened blood pressure. Of the acute infections causing the disease the most important is syphilis, the others being the exanthems, influenza, and tuberculosis. Syphilis is the chief cause of arteriosclerosis in infants and young people. Of the intoxications, the chief exogenous poisons are alcohol, lead, and tobacco. The chief endogenous poisons are those of gout, diabetes, Bright's disease, and obesity. The result of the disease is a slow, progressive atrophy with gradual loss of function in all the areas supplied by a sclerotic vessel; and when the artery becomes finally obliterated, especially if it occurs suddenly, necrosis and gangrene of the part normally supplied by the sclerotic vessel occur. The premonitory symptoms of arteriosclerosis are frequently evident in a middle-aged patient who comes complaining of headache, drowsiness, morning fatigue, feeling more tired when he gets up than when he went to bed, ineptitude for work, coldness of the extremities, tinnitus, attacks of migraine or neuralgia, together with high-pressure pulse and accentuated second sound of the heart. On the other hand, a middle-aged man may have a feeling of good health and may be able to perform his usual tasks and yet may die from rupture of a brittle artery in his brains. Another type of patient is one who has eaten much and drunk hard; he has a persistent elevation of the arterial blood pressure, and for some years has been feeling unwell, suffering from insomnia, cerebral confusion, despondency, and nervousness. An early symptom of the general disease is a slight pallor.

2. **Rheumatic Fever and Rheumatoid Arthritis.**—J. T. Clarke summarizes the various theories of the etiology of rheumatoid arthritis as follows: (1) It is a neurosis; (2) there is a deficiency of lime salts; (3) it is due to a disturbance of metabolism; (4) it is caused by absorption from chronic sores such as those of pyorrhea alveolaris, or those in the region of the anus; (5) it is due to insufficient sweating; it has a relationship to rheumatic fever; it is a specific disease. Of these the first four are just as likely to occur in the tropics as in the temperate climates, and the fifth is just as likely to be an effect as a cause and is very variable in different people in the tropics. No. 6 of these theories is supported by the geographical distribution. Neither rheumatoid arthritis nor rheumatic fever occurs in the tropics, and both are common in certain parts of the temperate zones. The author adds to the reasons for believing that rheumatoid arthritis is a specific disease and that it may have a relationship to rheumatic fever or possibly require that disease as an antecedent; and believes that the knowledge that these two diseases are absent from the tropics may give a clue to their etiology, but especially to the etiology of rheumatoid arthritis. Egypt is regarded as providing an almost certain cure for rheumatoid arthritis.

3. **Landry's Paralysis.**—J. S. B. Stopford concludes that one will never know the precise pathological changes in Landry's cases. Several nervous diseases can produce an acute ascending paralysis. There is good reason to suppose that there is a distinct morbid condition causing a train of symptoms similar to those described by Landry and worthy of the name "Landry's paralysis." There is no advantage in retaining the alternative name "acute ascending paralysis," and the name "Landry's paralysis" should be strictly reserved for a special type of ascending paralysis which does not show the morbid changes of poliomyelitis, polyneuritis, etc.

4. **Constitutional Gastroptosis.**—J. J. Grace and W. Overend note that in constitutional gastroptosis the abdominal muscles are often firm and tense in comparison with their condition in secondary splanchnoptosis. One cannot, therefore, attribute the descent of the gastric viscus to an acquired laxity of the abdominal wall. The genesis is to be ascribed to the existence of prolonged attachments due to a deficient development of embryonal adhesive processes. This defect is reinforced by the presence of a narrow upper abdominal opening, by downward displacement of the diaphragm, and by certain osseous changes which take place at the age of puberty. It is, in fact, a partial indication of a general innate or embryonal anomaly, in which an aberrant configuration of the chest, elongated ligamentous bands of the abdominal viscera, prolapse of the stomach, liver, kidneys, terminal ileum, cecum and colic flexures may one or all participate. Individuals of this habit, more especially men, often exhibit little or no digestive disturbances. There may be some gastric delay, with a tendency to diffuse habitual constipation associated with a liability, above the average, to impairment of health under conditions of strain.

1. Irregular Action of the Heart. C. Wilson.
2. Some Factors Concerning Amputations with Reference to the Present War. P. Lockhart-Mummery.
3. A Case of Acute Aneurysm of the Superior Mesenteric Artery, with Rupture. J. M. Cotterill and J. Miller.
4. Some General Notes on Suffocation by Poisonous Gases, with Detailed Notes on One Fatal Case. A. W. Hendry and E. L. Hersburgh.
5. Aneurysmal Varix of Popliteal Vessels from Gunshot Wound. R. B. Wright.
6. Anglo-French Hospital, No .2, Chateau Tourlaville, Cherbourg. M. L. Ramsay and F. A. Stoney.

1. **Cardiac Irregularity.**—C. Wilson describes the various types of irregular action of the heart. Sir James Mackenzie's work on arrhythmia and its developments are of epoch-making importance, and form solid ground on which one can base more accurate opinions and more definite statements than were formerly possible. Two baleful influences in connection with heart cases have long been at work—vague speaking, and the needless limitation of the patients' activities—and it was the recognition of these facts years ago that led the author to take a somewhat special interest in the heart. He came across numerous cases where patients had been told they had "weak hearts," and in which, though there occasionally was a murmur, and sometimes a loud one, he could discern no more evidence of "weak heart" than one might discover in a biceps whose owner had been told that he must only use it with great caution. Many means are at one's disposal for estimating a heart's reserve capacity; and among them a knowledge of the irregularities and their significance now occupies a prominent position. Ability to differentiate the rhythms will restore far more patients to activity than it will condemn, while in the case of those who may have to be restricted it brings the satisfactory assurance that the patients' lives will not be limited on insufficient grounds.

3. **Acute Aneurysm of Superior Mesenteric Artery.**—J. M. Cotterill and J. Miller report the case of a private who was admitted to the hospital complaining of severe abdominal pain and who was considerably collapsed. His temperature was subnormal, and his pulse thready and irregular. His bowels had not acted for three days. He had not vomited. His tongue was moist and clean. The abdomen was somewhat distended with gas; there was no abnormal dullness to be made out in either flank or elsewhere. Subjective pain was felt all over the abdomen, but tenderness on pressure was not noticed over any area in particular. A small enema was given, and this was followed by a slight normal evacuation of the bowels. After this the patient felt easier and slept for a short time. The heart sounds were feeble, but not otherwise markedly abnormal. Seven hours after admission the patient suddenly collapsed and died one-half hour later. It was considered likely that internal hemorrhage had taken place but he was too collapsed during the few hours he was under observation for laparotomy to be performed. At autopsy a thin-walled aneurysm about the size of a walnut was found in connection with the commencement of the superior mesenteric artery. This had ruptured into the substance of the mesentery and into the peritoneal cavity. The heart was enlarged and conical in shape. The cavities were uniformly dilated, and the muscle pale. The mitral valve was healthy. The segments of the aortic valve were thickened and covered with large friable vegetations. The lungs showed congestion and edema. Cultures were made from the vegetations on the aortic valve and from the spleen. Those from the spleen showed no growth. The cultures from the valve showed a pure growth of a staphylococcus which failed to develop pigment. The chief interest in this case lies in its rarity. Apparently the endocarditis and the hemorrhage had been in existence for a number of days as evidenced by the considerable amount of organization that had occurred.

Münchener medizinische Wochenschrift.

May 4, 1915.

The Louse Plague and the Prophylaxis of Typhus.—The military supplement of this number of the Wochenschrift contains a number of articles on these subjects. Nocht and Halberkann quote the opinion of Curschmann

that the louse cannot be the sole cause of typhus since even months after an epidemic the bedding, clothing and straw may convey it. The louse starves in a few days without food. Nits may be delayed to some extent in their hatching—from 2 to 4 weeks, according to several claimants—but the estimate that they hatch normally on the third or fourth day is too low. The entire matter needs careful study not only for the solution of the problem of the louse as a host, but for the more immediately practical one of disinfection. A constant following up of the egg cycle shows plainly that antiparasitic measures are often inefficacious. Freshly deposited eggs, which have not yet reached the respiratory stage, are harder to destroy than older ones. Too much cannot be learned in regard to the influence of heat, moisture, etc., on hatching. The authors recommend that dichlorobenzol be placed in sacks to be worn in each trouser leg and on each side of the chest. This substance is very volatile, and has to be renewed every three days. It is nearly odorless and inexpensive. These sacks may also be placed here and there in the bedding. They are of special value for lousiness in the badly wounded, and secure to these a good sleep. Wasielewski discusses chiefly the subject of the protection of physicians and nurses who care for typhus patients. He states that the body louse is the only known carrier of this disease, although the head and pubic lice, fleas, bed bugs and other bloodsuckers are under suspicion, to say nothing of infected material in patients when in the form of droplets projected into the air. However, as yet we do not even know enough about the body louse to secure its complete banishment. Some habits and attributes of the parasite are mentioned. Cold air makes it move more sluggishly, but even the freezing temperature does not prevent wholly its locomotion. Old observations show that opening the windows in cool weather was recommended as a prophylaxis against typhus. We find no mention of a kind of behavior seen in the skin dispensaries of New York, to wit: If a body louse was deposited in the center of a room with a coat hanging on the wall, it would almost unerringly crawl toward the garment and up the wall until it had reached the collar or upper portion. The rationale of such an instinct or tropism can only be conjectured. The author mentions the risk of throwing the outer clothing on the bed of a victim of lousiness; of riding in railway cars. Washable outer garments furnish no protection, for the lice readily go from these to the body linen and underwear. The author recommends the "louse proof" suits described in recent literature. Wulker states that two distinct campaigns must be prosecuted, against the lice and nits respectively. The latter may be submitted to microscopic control, and six well marked stages are recognizable, viz: (1) the freshly laid egg, full of yolk granules; (2) differentiation of yolk into uniform germinal spheres; (3) first outline of body of larva; (4) anlage of head, body and extremities; (5) fully developed larva; (6) hatched and empty egg. These stages require from four to six days at room temperature. Experiments with parasiticides must be carried out when the eggs are but one or two days old, when they are most hardy. If the egg continues to develop while under treatment with any of the numerous parasiticides, the conclusion must be that the substance is inert. Many volatile substances like ammonia, chloroform, tobacco smoke, have destructive power over the nits. Kulka, in a brief note, praises trichlorethyl as a parasiticide for lice. It is noninflammable. Its odor is, however, very objectionable, and the clothing, after treatment with this substance, must be exposed to the air for several hours or even an entire day in order to dissipate the disagreeable fumes.

Deutsche medizinische Wochenschrift.

May 6, 1915.

Case of Partial Soul Blindness, Optic Aphasia and Alexia.—Herzog reports the case of a soldier who suffered from the effects of a buffer accident involving his head, trunk, and pelvis. He had a contused wound of the head, which was the seat of severe pains; traumatic deafness, and at first suspicion of rupture of the intestine; pain in the pelvic bones and dysuria. As the other symptoms became less acute the deafness stood out prominently. The membrane was normal and there was no nystagmus, Kernig sign negative. Strength of arms subnormal; vertigo, even while in bed. Diagnosis of injury to the left temporal area of the brain. Transferred to neurological section. Mental tests showed good, rapid comprehension, correct memory and good judgment. The pupils, facial nerve, and tongue were normal. The disposition was "medium." No sense of smell. Total deafness, which was partly compensated by quickly attained ability in lip reading. Patient was unable to read either printed or written language and could not read his own handwriting. Letters he could read, a few, and his own name. He was, therefore, word blind, although in reality he comprehended the letters but was unable to name them. For many objects he had forgotten the names but clearly recognized their nature. Thus for "pocket handkerchief" he said "for wiping." Pince-nez he rendered "for seeing." He called a ewe a cow. He knew the word for knife but could not name the blade, etc., etc. As he was unable to name objects which he saw and comprehended, he was suffering from optic aphasia. There were numerous familiar objects which he could not comprehend by viewing them, but recognized by touch. Others he could not comprehend in any way, and having lost the memory pictures of these was also seen to have a certain degree of soul blindness.

Insufficient Results of Warfare Against the Clothes Louse.—According to Brauer all theoretic requirements have been fulfilled for getting rid of these parasites and their nits, but the plague still persists in prison camps and reserve hospitals. Those subjects who have been rendered louse free suffer from fresh invasions even when there has been no possibility of fresh accessions from without. While the head louse and pubic louse may exceptionally visit portions of the surface on which they do not generally occur, the clothes louse sticks to its own habitat faithfully if we are to credit all authorities. It is just here that our ignorance has come to light for the author hastens to assure us that this louse is now known to lay its nits in the pubic hair, not sparingly, but in huge quantities. Moreover, the author has also found nits in the axillary hair, perianal hair, hair on the thighs and legs. The error of medical men has been in confounding the body louse with the pubic louse, the latter being supposedly transmissible largely by intercourse of the soldiers with prostitutes. Nevertheless, instead of the well-known maculæ ceruleæ in the lower abdomen, which are characteristic of the pubic louse there is often present a melanoderma in the same area which characterizes the clothes louse. Finally the author has watched the hatching of young body lice in the pubic hair. Hence mere treatment of clothing with a simple bath and friction with some antiparasitic can exert little or no influence over nits in the pubis. It has long been known, moreover, that soldiers in a state of sexual abstinence have suffered severely, and over the entire surface, from the "pubic" louse (probably the clothes louse). The course to pursue is simple. All the old measures of warfare against the clothes louse should be kept in force and white precipitate ointment always applied to the pubes, axillæ, etc.

Insurance Medicine.

THE GENERAL FACTORS DETERMINING MEDICAL SELECTION.

FROM "ALLGEMEINE LEBENSVERSICHERUNGSMEDIZIN" BY PROF. DR. GEORG FLORSCHÜTZ OF GOTHA.

(*Continued from page* 1041.)

It is not our task here to penetrate into the nature of the diatheses, to discover the abnormal constitution of the organism or to study it more intimately as a substratum for disease. This is the affair solely of clinical medicine. We consider the pathological constitution as before only from the standpoint of a gross anomaly of constitution, and this method of consideration suffices here in order to attain that which alone we wish to attain, namely, the selection among applicants for insurance.

From remote times obesity in alternation or combination with gout and diabetes has played an important rôle in insurance medicine as well as general medicine, because it did not seem referable to any definite organic disease, but was to be regarded as a type of a constitutional affliction. Long since obesity was recognized as exerting an unfavorable influence upon the duration of life. But it was also recognized that not every fat man, because he was fat, must necessarily suffer from the short-lived constitutional form, and that differences existed here just as in thin subjects, which the medical examination is unable to discover. Life insurance medicine had long neglected the leanness of the applicant as a factor in selection, but it had early sought to discover some practical method of selection in the case of the overweights. In this case it was the weight which was first drawn into use as the measure of obesity, according to the well-known rule of Broca that the normal weight for adults amounted to as many kilograms as the number of centimeters of height exceeded a meter. As there was a hazard in the corpulent constitution, an applicant was accepted whose body weight exceeded the normal weight of an adult subject of the same age and height by a certain amount. Soon, however, life insurance medicine stood on its own feet in this matter. American societies formulated from their own material tables which gave the average weight of adults according to height and age in separate columns, and showed that a pathological supernutrition was present when the excess weight exceeded the average by 20 per cent. Othr insurance physicians sought, with the aid of formulæ, to draw the limits between normal and pathological corpulency. Mahillon assumed that corpulence began when the weight expressed in kilograms attained a figure which is larger than one-half of the height as expressed in centimeters. Norton regarded subjects as fat whose girth exceeded the chest circumference at inspiration. Maurel regarded a subject as fat whose weight exceeded the average by 10 per cent. Finally Pignet estimated corpulence according to the remainder obtained by subtracting from the number of centimeters in height the figures obtained by adding the number of centimeters of chest measurement and the kilograms of weight. If the applicant was to be regarded as insurable this remainder should be 10 or more.

The author personally has found the following formula, mentioned by an author unknown to him, to be the most serviceable: Multiply the girth (in centimeters) by 2 and subtract the height. The remainder is expressed by 2 G—H. Now divide the height by the remainder $= \frac{H}{2\ G-H}$. If now the quotient is 5 or more a good average nutrition is present; but if the quotient is under 5 the applicant is corpulent, and the further it drops below 5 the higher the degree of corpulence. This formula also seems to me to be especially useful because it entirely eliminates the weight and depends solely upon the measurements with the tape. For readily as I recognize that the body weight is a thoroughly practicable standard for the somatic constitution, I am in like manner skeptical as to the statement regarding weight given by the applicant. Every physician controls a tape measure, but not the scales of the subject. The weight is in many cases inserted in the application blank solely on the statement of the applicant, and little credit can be given it.

From these defects measurements with the tape are not only free, but the ratio of girth to height can replace fully the weight in determining the constitution of the corpulent, as I have convinced myself through special investigations. For the sake of completeness I mention only that in order to exclude the sources of error in the variable structure of bone and development of muscle in determining obesity according to weight, one has proposed the introduction of special measurements for bone and muscle. The first is determined by the circumference of the fat-free segments of the leg and forearm, and the last of the difference in the biceps measure when relaxed and contracted. Certainly these propositions look correct, but burden an examination more than they could aid it in the selection. For aside from the excessive degrees, the intensity of the corpulence determines the selection just as little as leanness determines the tuberculosis hazard. Both are only the basic factors about which are grouped all other factors which affect the prognosis. In this case the leading ones are the elements which have caused the corpulence or maintain it, while next in order come the changes which corpulence has brought about.

Those cases are always to be deemed the most unfavorable in which the hereditary taint points to the constitutional form—to the appearance of corpulence in early life or its association with gout, gallstone disease, etc. The most favorable cases, on the other hand, are those in which corpulence first appears in advanced years, the family history also showing that the condition, if present in parents or ancestors, has never led to premature death.

Of acquired causes chronic alcoholism stands at the head and is to be regarded as the most serious. Pelloutier in his "History of the Celts" (vol. II, p. 15), which appeared in 1770, says: "The embonpoint of the Celts proceeded infallibly from beer. At least it is certain that one no longer finds, either in Spain or among the Gallic or other races, so many people of vast corpulence as in Germany." The same thing was said by the chief physician of the Mutual Life Insurance Company, Dr. Norton, at the Third International Congress of Insurance Physicians at Paris, when he designated the Germans as poor risks because of their corpulence; and he closed his remarks with the statement that according to all statistics there could not be the slightest doubt that the corpulent Germans, who are beer drinkers, should be held, in respect to duration of life, as exceedingly poor risks.

(*To be continued.*)

Book Reviews.

THE ANATOMY OF THE DOMESTIC ANIMALS. By SEPTIMUS SISSON, S.B., V.S., Professor of Comparative Anatomy in the Ohio State University, Columbus, Ohio; Member of the American Association of Anatomists; Fellow of the American Association for the Advancement of Science. With 725 illustrations, many in colors. Second Edition, entirely reset. Price, $7.00. Philadelphia and London: W. B. Saunders Company, 1914.

THIS handsome volume contains an account of the structure of the horse, ox, sheep, pig, and dog. It is essentially a work on systematic anatomy, but the topographical aspect of the subject is by no means neglected. The author has managed to keep the volume within reasonable limits, largely by omitting details of embryology and histology. Nearly all eponyms have been omitted, and the synonyms have either been left out or relegated to footnotes. In this edition the illustrations have been increased by nearly fifty per cent., and nearly all of these are reproductions of photographs taken by the author. The printing and illustrations are excellent, and the volume should be welcomed by teachers, students, and practitioners of veterinary medicine.

PROGRESSIVE MEDICINE. A quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by HOBART AMORY HARE, M.D., Professor of Therapeutics, Materia Medica and Diagnosis in the Jefferson Medical College, Philadelphia; assisted by LEIGHTON F. APPLEMAN, M.D., Instructor in Therapeutics, Jefferson Medical College, Philadelphia. Price, $6.00 per annum. March 1, 1915. Philadelphia and New York: Lea & Febiger.

THE current number of Progressive Medicine contains the following articles: Surgery of the head and neck, by C. H. Frazier; Surgery of the thorax, excluding diseases of the breast, by G. P. Muller; Infectious diseases, including acute rheumatism, croupous pneumonia, and influenza, by J. Ruhrah; Diseases of children, by F. M. Crandall; Rhinology and Laryngology, by G. B. Wood; and Otology, by T. L. Saunders. Items of more than ordinary importance are the contributions on the cerebrospinal fluid, the hypophysis, and exophthalmic goiter. They should be read by the physician as well as the surgeon. This number maintains the usual standard of excellence achieved by this publication.

THE PROBLEM OF CANCER or the Philosophy of Malignancy. By EUGENE COLEMAN SAVIDGE. New York: William R. Jenkins Company, 1915.

THE material of which this book is composed was in part originally included in "The Philosophy of Radio-Activity" by the same author, and in part consists of reprints of two articles by him. He endeavors to defend the hypothesis that there is a close relation between malignancy, obesity, and glandular activity. The lack of success which he has attained is due largely to the obscurity of his style so that it is very often difficult to determine just what the author is trying to say. A couple of quotations will indicate its nature. "The incontinent nucleus, whose chromatin escapes into the cytoplasm, is characteristic of the malignant cell. This is analogous with the involuntary passage of urine and feces; or dilated pupils, or involuntary sex dreams, in the individual. It is a true incontinence due to the removal of some central control." "It is as if malignancy were all maleness, or all femaleness, respectively, dissolved from the tissue cells."

CLINICAL DIAGNOSIS. A Manual of Laboratory Methods. by JAMES CAMPBELL TODD, Ph.B., M.D., Professor of Pathology, University of Colorado. Third Edition, Revised and Enlarged. Price, $2.50 net. Philadelphia and London: W. B. Saunders Company, 1914.

THIS book, designed for the student and practitioner rather than the trained laboratory worker, places chief emphasis upon methods and microscopic morphology rather than upon the clinical significance of findings. In this edition are included many of the recent methods which have proven valuable and helpful. There are a few statements to which exception must be taken as that on page 98 where the author says that phloridzin "is transformed into glucose by the kidneys of healthy persons." This is not in agreement with the action of the drug so far as we know it. The advice given on page 130 to clear urine if necessary with talc or charcoal before testing for albumin is unsafe as it neglects the possibility of some of the albumin being absorbed by the powder. He does not emphasize sufficiently the possibility of blood on a stomach tube being traumatic in origin. While the book does not pretend to be an exhaustive treatise it gives most of the accepted methods and would prove a valuable aid to the average student and practitioner. The advisability of including the Wassermann and Abderhalden reactions in a work of this character is debatable, though if a man has at least read over the technique he is perhaps in a better position to assimilate the results. Todd's statement, "It may be flatly asserted that the correctness of Abderhalden's thesis has been abundantly confirmed," is a little more than we should be willing to admit in view of the recent work of Bronfenbrenner. The work is attractively bound for laboratory use.

LEHRBUCH DER INFEKTIONSKRANKHEITEN für Ärzte und Studierende. Von Professor Dr. G. JOCHMANN, Privatdozent an der Universität Berlin, Dirig. Arzt der Infektions-Abteilung des Rudolf Virchow-Krankenhauses, Mitglied des Konigl. Instituts für Infektions-Krankheiten "Robert Koch." Price M. 30. Berlin: Verlag von Julius Springer, 1914.

THE title of this volume might perhaps better have been the acute infectious diseases, since syphilis and the chronic forms of tuberculosis have not received consideration. Acute miliary tuberculosis is included. Gonorrhea and lobar pneumonia are discussed only in their relation to general gonococcus and pneumococcus sepsis. It is a most exhaustive work, filling nearly a thousand pages and containing numerous illustrations and temperature charts. It is obviously impossible to review the work in detail, but it may be said that each disease is discussed thoroughly in every respect and that the sections on treatment are more satisfactory than is usual in books of this type. The author is not very enthusiastic about the results of vaccine therapy. There is appended a valuable chapter on disinfection. The book can be recommended freely to all practitioners.

AN INTRODUCTION TO THE STUDY OF COLOR VISION. By J. HERBERT PARSONS, D.Sc., F.R.C.S., Ophthalmic Surgeon, University College Hospital; Surgeon, Royal London (Moorfields) Ophthalmic Hospital. Price, $3.75 net. Cambridge: At the University Press; New York: G. P. Putnam's Sons, 1915.

THIS volume of 308 pages is probably the most comprehensive presentation of the subject from the viewpoint of the ophthalmologist that exists in the English language.

Part I is devoted to a consideration of the chief facts of normal color vision. The physical, physiological, and psychological elements in color vision are presented, the arguments based on a comprehensive knowledge of the facts in our possession. The bases of color vision in the spectrum; the field of vision for colors; the flicker phenomenon; after image; evolution of color vision, etc., are discussed.

In Part II the chief facts of color blindness are presented. A chapter each is devoted to dichromats, trichromats, and monochromats.

Part III deals with the chief theories of color vision. Section I is devoted to a general review of the color theories; then follows a discussion of the various principal theories separately and in detail. The writer has carefully analyzed the obtainable data in a masterful manner, and has given us a dependable work on the subject that will not be readily superseded. It should be read by all who practice ophthalmology.

INTERNATIONAL CLINICS, a Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, etc. Edited by HENRY W. CATTELL, A.M., M.D. Volume I. Twenty-fifth Series. Price $2.00. Philadelphia and London: J. B. Lippincott Company, 1915.

THIS number contains twenty-one articles on Diagnosis and Treatment, Medicine, Surgery, and Medical Economics. William Osler has a few remarks on the Diagnosis of Polycystic Kidney and Harlow Brooks has an excellent article on the Heart in Syphilis. A summary of the Progress of Medicine During the Year 1914 touches most of the new developments in medicine for the year. The number is well up to the average standard for this excellent quarterly.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Sixty-sixth Annual Session Held in San Francisco, Cal., June 21-25, 1915.

(Special Telegraphic Report to the MEDICAL RECORD.)

HOUSE OF DELEGATES.

Monday, June 21—First Day.

THE PRESIDENT, DR. VICTOR C. VAUGHAN OF ANN ARBOR, MICH., IN THE CHAIR.

President's Address.—Dr. VICTOR C. VAUGHAN, in his address sounded a warning to the American medical profession that it was falling behind in its realization and practical application of the many and great advances that had been made in recent years in the department of preventive medicine. Indeed, many intelligent laymen at the present day knew more of the science of public health than did the average physician, and they were quite generally supplanting medical men in the practical application of the recent discoveries in preventive medicine. Michigan had recently appropriated $1,000,000 for the study of the prevention of tuberculosis and a small committee had been appointed to carry out this work, three members of which were non-medical men. This condition should be remedied and the profession should be aroused to a realization of its duties in this respect. Post-graduate study in this country is not what it should be, and the speaker said it should seriously be considered whether it might not be possible to send clinical teachers through the various States to give post-graduate courses in small towns and districts remote from medical centers.

Report of the Secretary.—Dr. ALEXANDER R. CRAIG stated that the membership of the Association on May 1, 1914, was 41,029; on May 1, 1915, it was 42,366, showing a gain of 1,337 for the year. A communication was submitted from the Medical Society of the District of Columbia objecting to the ruling that a member changing his location thereby forfeited membership in the American Medical Association by the end of one year unless he had in the meanwhile affiliated himself with the local medical association. It was suggested that this period be extended so that a member of any constituent society removing from the jurisdiction thereof might retain his membership in the American Medical Association for a period of eighteen months following removal, after which such eligibility should cease, unless it had been reestablished by the individual becoming a member of the constituent society within jurisdiction of which he was located. A resolution was submitted proposing for honorary membership in the Association Drs. Arndt of Berlin, Foerster of Breslau, and Wilfred Harris of London.

Report of the Board of Trustees.—Dr. WILLIAM T. COUNCILMAN of Boston reported that the weekly issue of the journal was now 63,000, an actual increase of 3,177 over that of the year 1913. The trustees regarded the *Archives of Internal Medicine* as a success, although it showed a financial loss. However, the *American Journal of Diseases of Children* had been a complete success, and already showed a slight profit. The cooperative medical bureau had been found to be a stimulus to the State journals in many ways, and was now used by twenty-four of these journals. Other improvements in the way of make-up and contributions had been effected in the State journals through the influence of this bureau. Advertisements to the amount of $10,000 for the benefit of these journals had been secured by the bureau. Last year the trustees called attention to the fact that the extension of various activities of the Association had used up the profits to the vanishing point. This year, however, there was a better showing, but the balance was only $3,984. The property and equipment of the Association, less depreciation, was valued at $328,656, and the reserve fund which had been created amounted to $118,832. It had been resolved that this fund should not be drawn upon except by the affirmative vote of seven trustees, and that it should be added to yearly. The expenses of the Association should not be allowed to increase, but they should on the contrary be decreased steadily. The work of the Propaganda Department had been continued during 1914 on the lines previously outlined, and a steadily increasing interest had been noted on the part of the public in the education work of the Association relative to medical frauds. Very many newspapers, magazines, and lay organizations were helping in this work. The lantern slides issued by the Propaganda Department were in great demand, as also were the educational posters. There were now listed twenty pamphlets on medical frauds, dealing with 288 individual preparations. Several law suits had been brought against the Association because of the exposures of the Propaganda Department; all of these had been withdrawn, however, but one, which the Association was fully prepared to meet. Dr. Councilman presented a supplementary report of the Council on Pharmacy and Chemistry, which the trustees had discussed at their February meeting. Although they appreciated that a vast amount of good had been done, nevertheless they could not but feel that the material results were far below what they should be. The main reason for this was that the Council was not receiving the active and hearty support of the profession, individually and collectively. In fact there was considerable indifference on the part of the medical profession. If its work was to be continued, the Council must have the strong and practical support of the physicians of the country. The trustees had passed a resolution appointing a committee to prepare an Address to the Profession on the use of proprietary drugs, and on the work of the Council of Pharmacy and Chemistry. This address would be presented to the House of Delegates, and sent officially to the presidents and secretaries of all the State and County Medical Societies. This address stated that the first duty of the physician was that of service to mankind, and the object of the American Medical Association was primarily to make this service more effective. This wide view made necessary an active and strong opposition to certain evils which could not be successfully resisted by individuals. The most important of these evils was the commercial exploitation of the sick for pecuniary gain. The best efforts of the Association in time and money had been directed to the correction of such abuses. The great advances in medicine during the past 40 years had given an opportunity for the exploiter of patent medicine. The low grade medical school had produced some men of ability, but the average graduate of such schools was the one who would give testimonials in favor of proprietary medicines. The medical journals were no more adequate to the task of leadership than were the medical colleges, for these journals necessarily relied on the advertisements of proprietary medicines for a part of their income. The Council on Pharmacy and Chemistry had been created to counteract these evils, and to publish facts regarding new and non-official remedies. It had also undertaken the simplification of the materia medica, having published a volume entitled "Useful Drugs." Its function was therefore to do more than merely pass on proprietary remedies. The influence of the Council was seen in changes in the curriculum of medical colleges, and its influence had extended even to Europe. Young men now entering the Profession were no longer afraid of unscrupulous educators. The medical college problem had been practically solved, but the situation regarding medical journals was but slightly better than before. There were many more journals than were needed and the major portion of the smaller ones depended entirely upon nostrum advertisements for their support. The remedy for this, as had been shown many times, was in the hands of the readers and of contributors to these journals. The elimination of advertisements not approved by the Council would necessarily eliminate a number of journals, just as the introduction of a higher standard of medical education had eliminated the low grade medical colleges. The trustees presented a resolution for adoption by the House of Delegates endorsing the work of the Council on Pharmacy and Chemistry, and encouraging it to further efforts in the attempt to overcome this evil.

Report of the Judicial Council.—Dr. ALEXANDER LAMBERT presented this report, in which it was suggested that the same privilege under proper restrictions be extended to physicians living near State lines, as was extended to those living near county lines; namely, that the man living near a line, either State or County, should be permitted to hold membership in the State or County Society the meetings of which he found the more easy to attend, provided, however, that the State or County in which the individual practised waived jurisdiction over his membership. There had been an increasing number of charges of various of-

fences against members of the Association, and it was apparently accepted by many that the judicial Council was able to accuse an individual and then to judge him. This, of course, was impossible, and it would seem wise that the House should consider the passing of a standing rule, designating a method of procedure, by which the Association could protect its fellowship. This would be done if the Judicial Council directed the Secretary of the Association to file charges against any fellow when any overt act on his part supported by reasonable evidence was brought to the attention of the Secretary. The Council reported upon the results of an investigation made regarding the commissions paid by surgical instrument makers to physicians and surgeons. This evil apparently prevailed in all parts of the country. It should, however, be understood that physicians could not honorably receive a "rake-off" from the instrument maker. The remedy for this was that the surgeon should exact a sufficient fee from the patient himself for the services rendered, and that the instrument maker should charge only what would give him a legitimate profit. It had been suggested that the American Medical Association should undertake the task of defending members in malpractice suits. In the opinion of the Council such action would come under the head of "benevolent work" as did also the suggestion that the Association furnish funds for the support of widows and orphans of medical men. Such work belonged to the State and County Societies, and should not be undertaken by the National body. Workingmen's compensation laws were being passed in various States, and this gave rise to certain economic conditions which presented many new problems for the medical profession. It was felt that the Judicial Council should describe these laws and discuss their social and philosophic foundations. Information regarding these laws had not yet been systematized, but the Council had sought to make a general review of the subject. The European conception which had been but recently adopted in this country was that injuries to working men should be regarded as risks of industry, and should be classed in the same category as wear and tear, and other expenses of production, and should be paid for accordingly. Most European countries were further advanced in this matter than were the States in this country. The report presented a review of accident insurance, compulsory sickness insurance, old age insurance, pensions for widows and orphans, and maternity insurance in the United States and other countries. In this summary of various social insurance laws, it would be seen that there existed in Europe a tendency toward a complete group of laws protecting industrial workers against accident, sickness, maternity, funeral expenses, granting pensions for partial disability or complete invalidity, pensions for widows and orphans when the bread winner had been killed, pensions for early old age brought about by industrial conditions, for physiological old age, when in the natural course it brought the wage earner to a complete inability. These problems were exceedingly interesting. The organization of physicians in Germany had been so effective that only 150 physicians out of the 33,000 in the empire could be induced to accept physicians under the insurance societies against the advice of the Liepzig league. Although the British Medical Association had expended a large sum for the protection of its members, the results of the National Insurance Act had been different from what had been anticipated. The Government had distributed among physicians $20,500,000, an average of $1,150 for each physician. There had been in this country a tendency to criticize the cost of medical service under the Compensation Laws, but after a careful analysis of the wages and fees in different parts of the country, it had been shown that the charge that there was a general endeavor among surgeons to demand more than their due was absolutely false. In considering the formulation of any new fee bill, it was well to remember that three-quarters of all accidents required less than two weeks' care, and that the daily visit to the house, or the daily office or dispensary visit, formed a large item in the total amount of surgical compensation. Further in considering the fee for fractures one should remember that an amputation for which a higher fee was granted usually required vastly less skill from a surgical standpoint than the treatment of fractures. Moreover, so far as the economic results of the patient were concerned, a fracture offered some hope of permanent rehabilitation, whereas amputation left partial or total disability. The work on fractures would in future stimulate the surgical profession to the employment of its ingenuity and skill in order to obtain the best results. It would in future require much greater judgment and skill in fractures than in any other form of injury to obtain the minimum disability, and such judgment and skill demanded a high rate of compensation to the medical man. The Judicial Council had presented this lengthy report because in the near future a majority of medical men in this country would be obliged to face new social conditions. The tendency was toward a complete insurance system, such as was now enforced in England and Germany. This would unquestionably tend to improve the social condition of the community, and in the carrying out of any scheme looking to human benefit the Medical Profession must necessarily be included, whether it be to pass upon sickness or health insurance, whether it be for mitigating the injury to the individual from accident, or whether it be for spreading the diseases in the community at large. The Medical Profession would however accept the responsibility in these new conditions, as it had always accepted responsibility in the past.

Report of the Council on Public Health and Public Instruction.—Dr. F. C. GREEN presented this report. During the past year the council had developed the program outlining a thorough investigation of public health conditions in the United States, with a view to securing more accurate information on all phases of public health. This program embraced the education of the public by every possible means, in order that the people might understand the enormous advances that had been made in scientific medical knowledge during the past generation, and the possibility of utilizing such knowledge in the prevention of disease, the prolongation of human life, and the reduction of the death rate. It also aimed to crystallize this educated public sentiment in the formulation of public health laws, regulations, and ordinances, which would render possible a conservation of human life, and further to render such laws more effective through an educated and enlightened public opinion. Dr. C. V. Chapin, a representative of the Council, had made an investigation and comparative study of the activities, equipment, and accomplishment of various State health boards. During the coming year, municipal public health conditions would be studied in the same way. A report of various voluntary public health organizations had been prepared and was in process of publication. It showed that these organizations were in a most chaotic condition, resulting in an unnecessary duplication of effort, a waste of money and labor, and an interference in function. The publication of this report made this very clear and also supplied data for the formulation of a plan for better organization and conduct of such work. During the past year, the press bulletins had been sent out to many newspapers of the country, which were showing an increasing tendency to use this material and to credit the Association and the medical profession with sincerity and disinterestedness. Their mailing list contained approximately 2,200 newspapers. The Bureau of Literature had also prepared suitable material for distribution to the public. Various pamphlets on the conservation of vision, cancer, sex hygiene, medical defence, medical research, etc., had been published and distributed during the past year. The pamphlet entitled "Save Babies," by L. Emmett Holt and Henry L. K. Shaw, was particularly worthy of note, and its general distribution would be productive of the greatest good. With reference to the third function of the Council, formulating suitable legislation, they had during the past year published the digest of Supreme Court decisions on medical practice acts and on the powers and duties of State boards of health. Their collection of public health laws was practically complete to date, and had been of assistance to inquiry in drafting bills for presentation to State legislatures and in drafting municipal ordinances. This bureau had rapidly increased the amount of available material of all kinds relating to the legal side of medicine, and it was prepared to respond to all inquiries on the subject. One of the activities of many State societies was the protection of their members in malpractice suits. This meant that the States would have a collection of Supreme Court decision on this subject, and it would be possible for the medicolegal bureau to collect, classify, and index these, and keep them up to date, thus forming a central bureau of reference from which any committee on medical defence could secure information and assistance in preparing briefs. The most important national legislation enacted during the past year was the Harrison Act. Certain necessary burdens would

have to be borne under this law, and these the profession might be confidently relied upon to bear without complaint. The unnecessary burdens, those that the profession might justly complain of, time might be expected to cure, and only after it had failed to do so, should thought be given to a recourse to the Courts or to Congress for relief. It had become increasingly evident, as the work of the Council developed, that the chairman was eminently correct in the statement which he had made during the first year of the Council's activity, that its greatest usefulness would be found in acting as a center around which other organizations and activities could group, rather than in any independent work which it might itself accomplish. This fact was becoming each year more apparent. Probably the most valuable work which the Council had done was that of coordinating and harmonizing different groups of organizations, bringing them into closer relation with the American Medical Association, and promoting mutual understanding.

The Committee on Welfare of Women and Children had continued along the lines of the first year's work formulating plans for the measuring and scoring of babies. They emphasized the fact that this measuring and scoring should be regarded rather as a basis upon which to formulate plans for the development of the frail child, rather than a means of establishing a standard of the healthy and strong child. Their ultimate hope was that their work would pave the way for creating a permanent station where babies could be examined from time to time. The Children's Bureau of the Federal Government was in hearty sympathy with the work of the committee and had cooperated with them throughout the year.

The Committee on Cancer had devoted its energies chiefly to the educational pamphlets dealing with the subject of malignant disease in its various forms. The campaign thus far waged was yielding excellent results as evidenced by the number of cases of early cancer presenting for operation in various clinics and elsewhere. They felt quite sure that within the next five years every person in the United States would be so far instructed in this point as to realize that cancer if taken in time could in many cases be permanently cured.

The Committee on Expert Testimony had submitted a bill which was a product of committees appointed by the American Bar Association, the American Institute of Criminal Law, and the American Medical Association. This bill was limited to expert testimony in criminal cases in which the plea of insanity had been raised. It left untouched the bulk of cases in which medical men offered testimony, but for many reasons this was considered most suitable as the first step.

The Committee on Cooperation with the National Educational Association reported that it had secured the passage of resolutions by this Association asking for information regarding the hygienic and sanitary conditions of rural schools, and especially to ascertain what instruction was being given upon the subject of hygiene and sanitation. Committees of the two Associations had had several joint meetings in which they discussed the minimum requirements of rural schools. Seven hundred and fifty thousand copies of these requirements would be printed and widely distributed.

The Committee on Uniform Regulation of Membership reported that practical uniformity in membership regulation was gradually becoming to prevail in all the constituent medical societies of the country. This change was taking place through a recognition by the State officers of the need of simple uniform methods, both for managing the work of the State Societies and for coordinating it with that of other State Societies and of the National Association.

The Committee on Conservation of Vision reported success in the establishment of State lecture bureaus, 490 lectures having been given in thirty-eight States to upward of 114,000 people. The work had led many to see the need of examination of the eyes, ears, noses, and throats of school children, and of the teachers as well. The Wyoming law on this subject was particularly praiseworthy.

Report of the Council on Medical Education.—Dr. A. D. BEVAN of Chicago said that the report of the Council for 1905, just ten years ago, presented two educational standards, one of which was recommended for immediate adoption, and the other was referred to as the "Ideal Standard" for adoption at some future time. The first called for a greater medical course, consisting of four years of seven months each, following the completion of the usual four-year high-school education. The ideal standard called for a standard four-year high-chool education, a year devoted to a college course in physics, chemistry, and biology, a four-year medical course, and one year's practical training as intern in a hospital. The college session just closed marked an important epoch in the history of medical education, for with the exception of the hospital intern year, the standard which in 1905 was referred to as ideal, had become in 1914 the essential standard. Last autumn thirty-seven medical colleges began for the first time the inforcement of the entrance requirement of a college year in physics, chemistry, and biology, joining the forty-seven which had already attained that or higher entrance requirements, there being now altogether eighty-four medical colleges out of the 100 now in existence which were operating under the higher standard. Six medical colleges had already adopted the requirements of a fifth year as intern in a hospital before the M.D. degree would be granted. One of the most important functions of the Council was that of conducting clearing house operations regarding medical education and licensure. The statistics collected were very valuable. The total registration in the medical schools in the country for 1914 was 5,797—a reduction of 2,069 since 1906. A marked improvement in State licensure has taken place during the past year. Another very important work of the Council was the preparation of a report on the reorganization of clinical teaching, which would serve as a guide in this direction. This report had also formulated the plan which provided for the training of teachers. Every clinical department should be organized with this point in view. During the past year an inspection had been made of the post-graduate schools of the country. As a result of this investigation the Council recommended that a distinction be made between advanced courses and more elementary courses in which the bulk of the work would be regarded as belonging to practitioners' courses. It was recommended that in determining the standard of graduate departments of medical schools, or of independent schools giving instruction to graduates, the Council should be guided by an outline, grading the various institutions on a Civil Service basis, in a manner similar to that employed for under-graduate medical schools. In graduate medical instruction only a bare beginning had been made but there was promise of more rapid development under the direction and with the assistance of the Council. A further investigation of hospitals was highly important, not only in the interest of medical education, to enable the Council to prepare lists of those in position to provide acceptable interneship for medical graduates, but also, and even more important, to lead to the publication of such information as would result in an improvement in the hospitals generally, and in greater efficiency of hospital management.

Report of the Red Cross Committee.—Dr. GEO. M. KOBER of Washington reported that 296 County Medical Societies had created committees for Red Cross medical work, and that there now were 510 committees composed of 2550 representative medical men in 48 States, which were available to render reliable advice or assistance in Red Cross work. During the past year many of these committees had been called upon to report of the qualifications of physicians and surgeons offering to serve in Europe, and their recommendations have been invaluable.

Report of the Committee on Scientific Research.—This Committee reported that its credit was completely exhausted, and it deeply regretted that it could make no further grants for the present.

Report of the Committee on Nomenclature and Classification of Diseases.—Dr. CRESSY L. WILBUR of Washington reported that owing to the European War the expected cooperation with the committee of the Royal College of Physicians of London on the fourth decennial revision of the English Nomenclature had not materialized, and he thought it might be well to wait for this as very probably it would be found to be an excellent system for adoption by American physicians with such slight changes as might be necessary for this country. Moreover, the International list of the causes of death and disability would soon be at hand. Studies like those of Cabot and Emerson, with respect to uncertainty in clinical diagnosis pointed to the necessity of devising the statistical classification so that prominence might be given to the more certain and definite returns. In view of these facts it might be expedient to discharge this committee for the present.

Report of the Committee on Anesthesia.—This committee reported that it had arranged with the *Journal*

of the American Medical Association for the publication of monographs on intratracheal insufflation by Meltzer, and on the Theory of Anesthesia, by Evarts and Graham. The plan was to bring out similar monographs from time to time in the hope that men of training and ability to do valuable work might be stimulated by the inducement of having their results published by such an organization as the American Medical Association.

Report of the Commission on Section Work.—Dr. HUGH CABOT of Boston reported that this committee had made a study of the sections and of the section work with a view to its rearrangement. Membership in the Association consisted, and probably always would consist of general practitioners, and the importance of making the scientific work of the Association of the greatest value to this, the majority membership, should not be lost sight of. Should too high a degree of specialization occur, the great educational function of the Association might be impaired or lost, with the result that the meetings would be simply a gathering place for groups of highly trained special workers. On the other hand, since the Association included among its members probably a majority of the most highly trained medical scientists in the country, it was very important to provide an opportunity to meet these men in discussion of scientific work of so highly special a nature that it was of necessity beyond the grasp of the great number of members of the Association. The committee suggested that instead of the present 15 sections, a division of the work into four groups be made as follows: Medical Science, including Anatomy, Physiology, Pathology, Bacteriology, and Pharmacology; Medicine, including the Practice of Medicine, Diseases of Children, Mental and Nervous Diseases, Preventive Medicine; Surgery, including General Surgery, Obstetrics, Gynecology, Genitourinary Surgery, and Orthopedics; Pure Specialties, including Ophthalmology, Otology, Dermatology, Stomatology, Gastroenterology, and Proctology. A study of the subject had convinced the committee that this section work must change from time to time as the science of medicine developed, and that it was therefore desirable to create a body having a continuity of service. It consequently recommended the appointment of a Council on section and section work, and suggested that necessary changes in the by-law be made to meet this new arrangement. The President appointed as a committee to consider the advisability of this change, Drs. Hugh Cabot, of Boston; Hass of Michigan, and V. G. Gecki, of California.

The various reports which had been presented were then referred to their respective reference committees.

Tuesday, June 22—Second Day.

This was a very brief session devoted to the reports of the various reference committees. Most of these were to the effect that the council and committee reports presented on Monday be accepted with few and unimportant changes. Regarding the report of the Committee on Expert Testimony, it was deemed advisable to let the the tentative bill regulating expert medical testimony liz over until next year as there were certain changes which the committee thought should be made before definite action was taken on it. Certain minor changes were also suggested in reference to the report advising a new arrangement of section work.

OPENING MEETING.

DR. VICTOR C. VAUGHAN OF ANN ARBOR, MICH., PRESIDENT, IN THE CHAIR.

Invocation.—The Rt. Rev. WILLIAM FORD NICHOLLS, Episcopal Bishop of California, made the opening prayer.

Address of Welcome to San Francisco.—Mr. JAMES J. RAINEY, representing Mayor Rolph, welcomed the members of the Association to the city. He said that he understood there were representatives present from all parts of the country, and he had been told that their principal work was devoted to putting themselves out of business. That was what preventive medicine meant. San Francisco more than any other city had cause to bless the name of preventive medicine because it had done more for San Francisco than for any other city. He said that he felt he was talking to one of the greatest and also to one of the most expensive bodies in the world. He did not mean this as a joke, and he did not refer to the cost of their services. He was thinking rather of the fact that the education of a medical man was more expensive than that of any other profession or class, not even excepting lawyers. The public ought to think well of medical men, especially the public of San Francisco, for they realized fully what medicine had done in keeping plague from the city. He was glad of the privilege of expressing to them in person his own and the city's debt of gratitude.

Address of Welcome to California.—Mr. CHESTER H. ROWELL, representing Governor Johnson, extended the welcome of the State of California to the members of the Association. He said he had been called upon to welcome many organizations this year to California, but he felt it was his proudest privilege to address this body which should be the proudest body of men in America. They might indeed well be proud for the part which they had taken in making the Canal Zone a place fit to live in. The medical profession, he said, stood committed to truth, and although there were many forms of error, truth was one. They would doubtless always have differences of opinion among themselves, but they would not insist that these different opinions, based possibly on imperfect knowledge, were virtues. Medical men stood committed to the unity found in truth through which they elevated the professional standard, and protected the public. They were also committed to the task of enlightening the minds of the public in health matters. They had devoted themselves to the alleviation of physical ills, and to the illumination of the darkness of ignorance. There was still much ignorance in the public mind in regard to medicine, and many even yet believed it was a magical art, and that some physicians possessed certain secrets or certain remedies whereby they could work miracles. On the other hand, there were many so conceited as to believe that they would diagnose their own condition and find a suitable remedy therefor. The public also believed that as in religion there were many creeds, one creed for the Methodist, and another creed for the Jew, so there were many creeds in medicine, and the medical creed that was best for any individual was the one in which he could place the most faith. The Association was to be congratulated on its lecturers, who were preaching a sound doctrine to some people. He himself had been present when brilliant lectures were delivered by superior men and were listened to by as many as 25 to 42 persons, who were already enlightened. He would not, however, disparage the effort for it was an entering wedge and much might be hoped from it in the future. He recalled that when he was a student at the University of Michigan 30 years ago, his fellow students who were looking for a "snap" course took in a lecture on sanitary science once a week. While they had some knowledge of the beginnings of modern medicine, many things that are now common, were then new. They were now giving a degree in sanitary science to many non-medical men, but the speaker thought that it would perhaps be a good thing if the physicians would monopolize this work, so that there would be no room for the lay-graduate in sanitary science. In closing he again referred to the great work that had been done by medical science in the sanitation of the tropics, and making possible the construction of the Panama Canal.

Address of Welcome by the Medical Profession.—Dr. H. M. SHERMAN of San Francisco, President of the Medical Society of California, welcomed the members of the Association on behalf of the Medical Profession of the city and State. He said that though they had come from northern Maine and southern California, from Washington and from Florida, they met as brothers who at home were doing the same things and trying to solve the same problems, in school, clinic, hospital, and for the public welfare. It was now 21 years since the American Medical Association had met in San Francisco, and many members of the Association thought that that was about the right time that should elapse before the next visit, but because of the great influence that the meeting of the Association exerted and because it was the inalienable right of the medical profession of California to return the courtesy which they had received at meetings in other cities and states, the Association should not object to coming to this city five times in a century.

President's Address.—Dr. WILLIAM L. RODMAN then delivered the Annual Address of the President, taking

as his subject "Work of the American Medical Association." The address was, however, not confined entirely to this subject but comprehended rather a general review of professional advancement in this country, including the work of the American College of Surgeons and the proposed establishment of a national board of medical examiners.

American College of Surgeons.—It was his duty and pleasure, as president of the American Medical Association, to congratulate most heartily the officers, board of regents, and fellows of the American College of Surgeons upon its auspicious beginning, its achievements, and its splendid aspirations. It had already accomplished much in elevating the general tone and level of American surgery and had met all reasonable expectations of its sponsors. The college was organized to fill a distinct need, and its aims and purposes were well presented by its president, Dr. J. M. T. Finney, at the inaugural meeting in Chicago, in November, 1913, in an address which was notable for its ability, sincerity, and lofty character. With a rare and keen discrimination, equaled only by the courage shown, he had pointed out the weaknesses in our armor, and the professional obligation of all to overcome them. Dr. Rodman said he could not do better than quote some of his forceful words, and, further, to express the hope that every member of the profession, in or out of the college, would read and read again the entire address: "The aim of this new organization and the reason for its existence lie in its disinterestedness and unselfish efforts to elevate the standards of the profession, moral as well as intellectual, to foster research, to educate the public up to the idea that there is a difference between the honest, conscientious, well-trained surgeon and the purely commercial operator, the charlatan and the quack; furthermore, that the term 'surgeon' means something more than a suave manner, a glib tongue, a private hospital, a press agent, and the all too easily acquired diploma. The standardization of surgery is absolutely essential to guard the public against such as these, as well as to preserve the honor of the guild itself. So far as the public is concerned, it is necessary to protect it from the wolves in sheep's clothing, from those who would prostitute their high office for the purpose of gain; from the ignorant and the untrained; from those who by reason of the lack of surgical judgment and skill are incompetent. That such are present in considerable numbers in our profession, and that they continue to ply their nefarious trade in every community of any size, with reckless disregard of the consequences, unfortunately cannot be denied. Are we to sit idly by while the fair name and fame of our profession are being dishonored and defiled? Is there nothing that we can do to protect the public and ourselves? Our presence here this evening is an answer to these questions. The American College of Surgeons has been called into being as an active, vigorous, virile protest upon the part of the profession itself against this unhappy state of affairs." In every community, Dr. Rodman continued, men were operating who had no right to take human life into their hands. This did not apply to the general practitioner who, in an emergency, and to the best of his ability, operated in an attempt to save life, but to those who, for gain, undertook that which should be done only by the skilful surgeon. Surgery was a special science, extrahazardous in its nature, and hence the public had a right to demand of the surgeon the very highest physical, mental, and moral equipment. The positive stand the college had taken on fee-splitting alone more than justified its existence. This evil had become intolerable, and a wave of protest was rising throughout the land which should and would overwhelm the offenders.

Council on Health and Public Instruction.—The function of this council was to investigate health conditions, to educate the public, and to foster a sentiment in the community that would force the enactment of health laws. The latter was important, for although the medical profession was better prepared than ever before to prevent disease and save life, it needed the confidence and intelligent cooperation of the laity before the work could be satisfactorily accomplished. The council was in touch with the newspapers and during the three years that the press bureau had been in existence it had issued 164 bulletins for publication in 4,900 newspapers. In Brooklyn there was a publicity committee which cooperated with newspaper editors in working out a plan for getting truthful reports of interviews on medical topics. This scheme had worked so admirably that the Judicial Council had recommended to the House of Delegates the formation of such a publicity committee in every county medical society in the country. Another plan of the council was to unite all of the public health organization into a national league. With this in view, it had suggested that the various public health organizations hold their 1916 annual meetings at the same time and place. Special societies, such as those for the study of tuberculosis, cancer, infant mortality, etc., could be made sections of this national league, which might be an advantage to them. The Bureau of Literature had circulated pamphlets on health topics, notably on cancer, which at this time was receiving great attention, not only by our Association, but by the American Society for the Control of Cancer, by a cancer committee appointed by the Clinical Congress of Surgeons of North America, and by various commissions, all working to the same end, namely, the enlightenment of the public as to the early symptoms of cancer, the necessity for prompt surgical intervention, and the danger of running after false gods. Many committees had done admirable work, notably the Committee on Resuscitation from Electric Shock, which had issued a chart and booklet for use in electric lighting plants which was considered authoritative all over the world; also the Committee on Resuscitation from Mine Gases, a report of whose work had been issued by the federal government. The Joint Committee with the National Educational Association had been engaged in a fruitful study of health problems in education which would give an impetus to sanitation in rural schools, hitherto much neglected. The activities of the Medicolegal Bureau were still in their incipiency, and it must be admitted that on the question of public health legislation the profession was still at variance. Efforts had been made, for nearly half a century, to secure the passage of laws regulating the practice of medicine in the different States, yet we failed to agree on the most essential requirements. The Association was, however, now making a more scientific study of medicolegal questions, and had issued two pamphlets dealing with this phase of its work. Nothing, however, could be more unwise or undesirable than hasty or ill-considered legislative experiments.

The Propaganda Department reported an increasing public interest in the matter of patent medicine frauds, and had issued more than thirty educational posters as well as lantern slides for popular lectures on this subject. Boards of health, clubs, and newspapers were alike active in disseminating information to the public.

Council on Pharmacy and Chemistry.—There were now three chemists in the laboratory of the Association who gave their whole time to the analysis of medicines, and although there was naturally much opposition to the work of the Council and some manufacturers had brought suit against the Association for what they regarded as unjustifiable condemnation of their projects, other manufacturers had voluntarily submitted their preparations to the Council for endorsement. In addition to the book on "New and Nonofficial Remedies" which contained a description of the new drugs and proprietary remedies which were deemed worthy the consideration of physicians, it had published "Useful Drugs," which contained a list of the really valuable drugs in our materia medica. This a number of the best schools now used as a textbook. Its labors, too, had materially influenced the teaching of materia medica and therapeutics. It remained, however, for the profession to set its ban on all proprietary medicines, if the only information concerning them came from those who manufactured and sold them.

Council on Medical Education.—This council was established in 1904 and its work since that time had more than justified its existence. It had accomplished more in the way of regulating and elevating medical education during ten years than had been done in a century before. It was only just, however, to acknowledge that there were outside influences which had been most helpful in this beneficent work, and to them all due credit should be given ungrudgingly. The Association of American Medical Colleges, the Federation of State Medical Boards, the American Academy of Medicine and the Carnegie Foundation had at all times cooperated cheerfully, zealously, and effectively. But, after all, it was to the greater credit of the Council that it had been able, largely through the tactfulness and diplomacy of its chairman, to make use of and coordinate so many forces for good, which, while working separately, as they hitherto had done, had oftentimes, though inadvertently, pulled apart instead of together. No one who had attended the annual meetings of the Council, Federation of State Medical Boards, and College Asso-

ciation, held on consecutive days, in the same hall, the members of each body having the privilege of debate in all, could fail to be impressed with the admirable team work thus far displayed.

When the Council was organized in 1904, it published, as an ideal standard to which it would gradually approach, the following: "(*a*) Preliminary education sufficient to enable the candidate to enter our recognized universities, the passing upon such qualifications by the State authorities. (*b*) A five-year medical course, the first year of which should be devoted to physics, chemistry, and biology, and such arrangements should be made that this year could be taken either in a school of liberal arts or in the medical school. Of the four years in pure medical work, the first two should be spent in laboratories of anatomy, physiology, pathology, pharmacology, etc., and the last two in close contact with patients in dispensaries and hospitals in the study of medicine, surgery, obstetrics, and the specialties. (*c*) A sixth year as an intern in a hospital or dispensary should then complete the medical course." This goal had now been reached, at least on paper; the ranks have been thinned, as more than a third of the schools were now *hors du combat*, and it was expedient to mark time for a while, and give those institutions which had approached the firing line at double-quick speed a chance to catch their breath. There were many reasons why this should be done. In the first place, the standard was now as high as it should be for *all* of the schools of the entire country. An irreducible minimum had been reached, and should be honestly enforced—that is, as soon as it could be. There was, of course, no limit to a maximum that any highly endowed and exceptionally circumstanced institution might adopt for itself. Second, the present standard of the Council (four years in an accredited high school, one year in the basic sciences of chemistry, physics, and biology) was on a parity with that of Canada and Great Britain, and with European countries. Third, medicine was not a thing apart, but only a link in the educational chain, and should be based on and correlated with the secondary schools, colleges, and universities of the country. Professional education, in medicine at least, had advanced much faster than our general educational system had done. It would therefore be logical to direct our efforts for the present toward stimulating progress in secondary education until it shall have caught up. It was the duty of the Council on Education to publish a list of acceptable and unacceptable medical schools; but the simpler the classification the better, as fewer mistakes would be made and, therefore, heartier support accorded by all. Nice discriminations between wholly acceptable schools were unnecessary, served no good purpose, would naturally be resented, and might lessen the usefulness of the Council. There was always danger of overdoing a good thing. It was proper and feasible to distinguish between schools which were acceptable and those which were not. But when the Council undertook to discriminate between high grade schools, mistakes certainly would be made. Therefore the Council had abolished "A plus" from its classification.

National Board of Medical Examiners.—To meet a situation which, under our peculiar form of government, had resulted in hardship and countless embarrassments, a national Board of Medical Examiners had been organized, the speaker said, and would hold its first examination in Washington in October. The character and scope of this examination would be such that no State ought to deny recognition, in the fullest sense, to those who had passed it. This board would not interfere in any way with the several State boards. It should be a simple matter to induce all of the States to recognize a national board whose only aim was to improve the existing situation, and remedy a defect in our law and form of government, provided such board gave an examination equal in every way to that required by the most exacting State in the Union. If this were done, then it would become the patriotic duty of the several States to recognize its licentiates, just as the provinces of Canada now recognized the examination of its national Board of Examiners.

The government had assented to the service on this board of the Surgeon General and an associate each from the Army, Navy, and Public Health Service, and, in addition, had promised the use of the government laboratories, hospitals and schools by the national board in conducting its examinations. The combined resources of these three government services were more than ample to meet every demand; moreover they would insure an examination of such character as was necessary, yet impracticable where large numbers of applicants were examined in one building, within a prescribed time, and by only a few examiners. With the resources available to the board, a number of men could be examined in the several laboratories, some might be given a practical examination in the hospitals, while others underwent written, and still others oral examinations, or operated on cadavers, all at the same time, but under different examiners. An executive committee of five members was perfecting details for the first examination, which would be held from October 4 to 11, and longer if necessary. The candidate for examination would be required to give evidence of having had: (*a*) A diploma from a high school of good standing giving a four-year course; (*b*) a satisfactory course in science, embracing physics, chemistry, and biology, of not less than one year; (*c*) four years in a medical school of A grade; (*d*) at least one year as intern in an acceptable hospital. The amount of the fee had not yet been determined, but it would probably be greater than that charged by the State boards yet less than the amount charged by the conjoint board of Great Britain, which was the equivalent of about $200. In addition the State boards, even though dispensing with an additional examination, would doubtless demand their customary fees as they do now when granting a license by reciprocity.

As to the personnel of the board, Dr. Rodman said, there would probably be fifteen members, several not having as yet been appointed. All sections of the country were to be repesented. As at present constituted, the board consisted of: Admiral William C. Braisted, Surgeon-General, U. S. Navy, chairman; Major-Gen. William C. Gorgas, Surgeon-General, U. S. Army; Gen. Rupert Blue, Surgeon-General, U. S. Public Health Service; Col. Louis A. LaGarde, U. S. Army, treasurer; Asst. Surg.-Gen. W. C. Rucker, U. S. Public Health Service; Commander E. R. Stitt, U. S. Navy; Dr. Herbert Harlan, representing the Confederation of State Boards of Examiners; Dr. Isadore Dyer, representing the Association of American Medical Colleges; Dr. E. Wyllys Andrews, representing the American College of Surgeons; Dr. Lewis B. Wilson, representing the Mayo Foundation; Dr. Victor C. Vaughan, representing the American Medical Association, and Dr. William L. Rodman, secretary, also representing the American Medical Association.

SECTION IN PRACTICE OF MEDICINE.

Tuesday, June 22—First Day.

Dr. THOMAS MCCRAE of PHILADELPHIA, CHAIRMAN.

Chairman's Address.—Dr. THOMAS MCCRAE of Philadelphia took as the subject of his address "The Use of Words." Words, he said, were the coin of mental exchange, and in medical science the choice of words was of great importance. Many vague terms in common use, often employed as a cloak for diagnostic ignorance, should be eliminated from the vocabulary of medicine. Such a term was "rheumatism." This was frequently applied to such diverse conditions as arthritis, osteomyelitis, neuritis, and the pains of aneurysm. This misuse of terms might not only cause a wrong diagnosis but might even lead to serious errors in treatment. Gonorrheal arthritis, for example, was often called gonorrheal rheumatism and this word suggested the use of the salicylates, which were of no therapeutic efficiency in such a condition. Again, the term asthma was very commonly wrongly employed, and when applied to the dyspnea of a myocardial lesion it often led to improper treatment. Temperature was another absurd word; it did not mean fever and one should not say a patient had no temperature when what we meant was that the patient's temperature was normal. Again, "case" was not synonymous with "patient." A very common misuse of a term was the employment of tubercular instead of tuberculous; tubercular was properly applied in the description of any disease in which there was tubercle formation, such as one of the forms of leprosy, for example; "tuberculous" signified infection with the tubercle bacillus. If medical men were more careful in their use of terms they would find as a result a greater efficiency in their work. They should exercise as much care in their choice of words in writing and speaking as they did in outlining their plan of treatment.

Phenoltetrachlorphthalein Test of Liver Function.—Dr. JAMES S. MCLESTER of Birmingham, Ala., read this paper. It was based upon results of the employment of the test in a series of unselected medical cases, includ-

ing a few of hepatic disease. Rowntree and his assistants had employed the test in sixty-seven cases, of which thirty-seven were quite severe, and they thought the fact of phenol excretion was of importance in diagnosis. Sisson had resorted to it in four cases with no definite results. Whipple, as a result of a number of experiments on dogs, had come to the conclusion that lowered functional capacity of the liver was attended with deranged pharol excretion. McLester had tried similar tests but concluded that they were of doubtful value. He had also found the carbohydrate, lipase, and nitrogen-partition tests of doubtful value; but the most material was the urobilin estimation. There were certain difficulties, however, in this. Wilbur says that the estimation should be made during a period of two weeks to eliminate the error resulting from the daily variations. In employing the method, phenol greatly diluted is given intravenously and then the feces for forty-eight hours are collected and examined. An output of less than 30 per cent. indicates functional or organic disease of the liver. Dr. McLester reported 100 cases, eleven of typical hepatic disease, sixteen of myocardial insufficiency, and the rest miscellaneous. In the liver cases the output of phenol was sometimes plus, sometimes minus; in the heart cases with liver engorgement the severity of the disease seemed to bear no relation to the phenol output, and the same was the case in tuberculosis with engorgement of the liver. The results were therefore inconclusive. The speaker questioned whether the amount of phenol output depended upon the functional capacity of the liver or whether a destruction of all powers was the active cause.

Dr. George Whipple of San Francisco discussed the clinical application of the test. He said that experimental work on animals was more satisfactory, for in them there was better clinical control and also more accurate control of the collection of feces. He had obtained positive results in intoxication, fistulas, and injuries of the liver. He thought one should be cautious in denying the value of a test such as this, nevertheless in complex liver conditions it was safer to have recourse to a number of tests, checking up one with the other.

Dr. Anderson of San Francisco said it was necessary to continue the observations for a period of at least two weeks before formulating any definite conclusions. One should make a distinction between experiments with a clinical object in view and those made for a scientific purpose. Animal experiments were convincing, but clinical ones were attended with so many disturbing factors that they were not so reliable.

Dr. McLester, in reply, thought that much work was still necessary to determine the value of the test; at present he could not regard it as any more certain than the nitrogen-partition test.

Leucemia—an Infection?—Dr. Ray Lyman Wilbur of San Francisco presented this communication. He said that medical men had a tendency to study the morphological rather than the etiological factors in the leucemias, but as yet it was impossible to say more than that a given case was myelogenous or lymphatic. Some observers regarded the condition as due to a neoplasm, but there was a growing tendency to consider the leucemias as of infective origin. The condition was probably occasioned by more than one microorganism, and an infection prepared the way for the next. Lymphocytosis was often confused with leucemia, and the occurrence of a high lymphocyte count in pneumonia and typhoid fever suggested the probability of an infection also in leucemia. The bone marrow afforded a convenient nidus for infection. Leucemia had been observed in chickens and other animals, and a passage through animals was possible. Familial leucemia had been noted and one case in the new-born had been reported. Corynebacteria and tubercle bacilli had been found, but it was improbable that they were the primary infective agents. Dr. Wilbur reported three cases in which there had been an acute course of about two months' duration with a gradual decrease in red cells and increase in white cells; the percentage of lymphocytes was as high as 99, and hemorrhages occurred. In one of the cases there was a mediastinal tumor, and in another there was also pernicious anemia with streptococci in the blood and bone-marrow. The bacteriological study of those cases was suggestive but not conclusive. Long-standing, low-grade infections probably played a part. It would be an important advance if the leucemias were proved to be infectious disease of human origin, but before this could be definitely proved the study of a long series of cases would be necessary. If foci of infection could be discovered the treatment should be directed against them.

Dr. Max Einhorn of New York said that the acute leucemias were probably of infective origin, though this was more doubtful in chronic cases. The tonsils might be the atria of infection. The bacteriological study of a case should always be made before the autopsy.

Dr. J. A. Lichtz of Pittsburgh said it was often very important to look for an infection in the cause of primary anemia. In the pernicious type the temperature was often elevated before death, which gave it the appearance of an infection. Perhaps leucemia might be caused by a virulent transformation of some previously non-virulent organism.

Dr. Wilbur said a careful study of the bone marrow in the living should be undertaken, a specimen of the marrow being obtained under local anesthesia. Whenever the tonsils were definitely diseased they should be removed.

Clinical Interpretation of the Platelet Count.—Dr. W. M. Duke of Kansas City, Mo., read this paper. Reports concerning the platelet count disagreed, he said, and the count followed no law in diphtheria, tuberculosis, and nephritis. He repeated the results of a number of experiments. In rabbits the injection of a fatal dose of diphtheria toxin caused a rapid fall in the count; but a sublethal dose was followed by a rise. Large doses of dead typhoid bacilli injected intravenously caused a fall in the count; small doses, a rise. Benzol in moderately large dose produced a rise; in small dose, a fall. The *x*-ray in large dose caused a fall; in small dose a rise. The same agent therefore might produce a rise or a fall. The injection of tetanus toxin produced little effect either way.

Dr. Webb of Colorado Springs said that the platelet count varied greatly; during the acute onset of a disease it might decrease, and later increase. It was possible that the use of the platelets was to carry opsonim. A high altitude caused an increase in the number of platelets.

Dr. Herberts of San Francisco said the platelets were discussed in hemorrhagic disease and also markedly discussed in aplastic anemia and pospurer. The patelets seen in coagulating blood are disintegration products of the leucocytes.

Dr. Duke said that hemorrhage occurred when the platelet count was below 10,000. The platelets were increased by the *x*-ray and in hyperemia. An important use was that they elaborated prothrombin when needed in case of injury to the vessels.

A Clinical Contribution to Our Knowledge of Chronic Pancreatitis. — Dr. Max Einhorn of New York presented this communication. He said the surgeons had contributed much to our knowledge of this subject, and so had the clinicians by their study of the function of the pancreas. Pancreatic disease was possible with increased activity of the gland. The clinical symptoms of pancreatic disease were diarrhea, fatty stools, emaciation, and atrophic changes. The diagnosis was often not made until the autopsy, and physicians were frequently timid about making a diagnosis *intra vitum*. Functional tests showed a charged trypsin and amylopsin relation. The digestive functions were defective for fat, starch, and albumin. In certain cases there was constipation with impaired digestion. Pancreatic disease was often associated with glycocuria. In 87 per cent. of diabetes the islands of Langerhans had disappeared. The pancreas was often affected in cases of gall-bladder disease. The gastric juice might be normal but the duodenal contents lacked the pancreatic ferments. Many cases recurred after operation. One of the etiological factors was alcoholism. In the treatment of pancreatic disease the cause (gallstones for example) should be removed if possible. Sometimes the disease was incurable and then our efforts should be described to maintaining the strength of the patient as long as possible and promoting his comfort as far as possible until the end. Acute pancreatis was not infrequently mistaken for cancer.

SECTION ON DISEASES OF CHILDREN.

Tuesday, June 22—First Day.

Dr. Lawrence T. Royster of Norfolk, Va., Chairman.

Chairman's Address.—Dr. Lawrence T. Royster of Norfolk, Va., delivered this address, in which he gave a brief history of the development of pediatrics and

made the prediction that the followers of this specialty stood at the threshold of a new era. Pediatrics was rapidly becoming recognized as the most important branch of medicine. It was a far call from the old woman nurse of a generation ago to the pediatrist of to-day. The requirements of a competent pediatrist now were a liberal education, general and medical, an interneship in a children's hospital, surgical training, and expertness in microscopical work. In addition he must be a leader of thought in his community and must be able to speak with authority on all matters pertaining to child welfare and the prevention of disease. His influence should be felt in the city council chamber, in the board of education and in all lines of sociological endeavor; indeed a thorough knowledge of sociology in all its bearings was most important. The child who was mentally abnormal was always less resistant to disease, and as there seemed to be an ever increasing number of children of this class it was important, if not absolutely necessary, that the pediatrist should be an alienist as well. It was only by constant study and practical post-graduate work at frequent intervals that the pediatrist could keep abreast of the times and fully acquainted with the best thought. This Section in Diseases of Children should be the clearing house for the entire country of the best work done in pediatrics each year, since many of the best pediatrists of America were members of it. The utterances of the Section as a whole should eventually become recognized as authoritative by the general public as well as by the medical profession. The best of the papers presented at these meetings should be selected for pamphlet distribution and a limited number of those, which might be suitable, should be given a wide publicity through the daily press. For this reason there should be a most careful censorship of all material presented. It would be well if a committee from the Section could be appointed to co-operate with the Child Welfare Bureau of the general government, with the American Association for the Study and Prevention of Infant Mortality, and with the several State boards of health, in studying the causes and the best means of prevention of infant mortality. Dr. Royster suggested that the American Medical Association might see fit to establish a Council on Infant Morbidity and Mortality, which could undertake the direction of child welfare work in an authoritative way throughout the country. Any body of men who were striving to better the race physically and to raise to a higher position the growing members of the human family could not possibly have too high ideals or be too well equipped for the service which they had undertaken to perform.

Recent Methods of Treating Diphtheria.—Dr. FRANK C. NEFF of Kansas City, Mo., presented this communication. After giving a brief summary of the work of Park and of Schick, he gave a report of the use of diphtheria serum in 155 cases at the Kansas City General Hospital. The mortality was 5.8 per cent. In the fatal cases the first dose of serum was administered on the third day on the average. The average number of units given at the first dose in the fatal cases was 6,100. Four of the nine deaths occurred within twenty-four hours of admission of the patient to the hospital. In spite of the greater severity of the disease the number of units employed when the serum was administered intravenously was practically no greater than in the milder cases. For the sake of greater security, however, more than was really necessary was given in the mild cases. The average dose in these cases was 6,000 units. In a general way it had been quite universally accepted that diphtheria should be diagnosed and treated at the earliest possible moment, and the delay incurred in getting patients to the hospital was that much time lost. To avoid this delay it had been suggested that the hospitals under control of the municipal health boards should extend their emergency service to include the immediate distribution and collection of culture tubes so that a positive diagnosis could be made and the administration of serum begun within twenty-four hours. As regards the administration of the serum, an intramuscular injection gave much more prompt and satisfactory results than a subcutaneous one, and there was no reason why the latter mode of administration should not be abandoned. An intravenous injection gave less discomfort than either an intramuscular or a subcutaneous one. The speaker knew of no contraindication to the intravenous method unless the occasional difficulty of finding the vein could be so called. In the series he had noted 24 cases of serum sickness. Eighty-one children had been tested by the Schick method; in 65 tests in infants under five months only one reacted to diphtheria antitoxin. There was definite evidence that the immunity of an individual might change from time to time, and the author had determined that the occurrence of a negative reaction shortly after exposure was of practical value as affording evidence that the individual lacked susceptibility at that time and that therefore a prophylactic injection of serum was unnecessary.

Dr. ZAHORSKY of St. Louis said that in his opinion the intravenous method of administration of the serum was not always practical, as it was sometimes followed by quite a severe reaction. He preferred in general the subcutaneous method in cases in which the circulation was good, the pulse was strong, and there was no lymphocytosis. If, however, the circulation was poor, as indicated by pallor and coldness of the extremities, one could not depend upon subcutaneous injections.

Dr. A. A. O'NEIL of San Francisco did not think the small doses recommended by Park were advisable, although it might be that diphtheria in California was of a more severe type than it was in the East, or possibly the speaker did not see his cases, as a rule, as early. He gave doses of 40,000 to 60,000 units, and even then he had to admit a mortality of from 12 to 15 per cent.

Dr. HENRY D. CHAPIN of New York said he had tried large doses and small doses and had found medium doses fully as effective as the large ones, and the failed to understand why such large doses should be regarded as necessary.

Dr. MCGAVIN of Portland, Ore., agreed with Dr. Chapin that it was seldom if ever necessary to give such very large doses. In the children's clinics in Vienna they never gave such large doses as were employed here. He inquired whether any members of the Section had observed good results from the use of diphtheria antitoxin in Vincent's angina.

Dr. W. W. BEHLOW of San Francisco disagreed with Dr. Chapin and McGavin in regard to the size of the dose of antitoxin. If large doses of the serum had been found to be effective, he said, he saw no good reason why he should risk the danger of small doses.

Dr. PHILIP S. RAY of Washington said that in his opinion the laboratory findings were so exact and so absolutely dependable that they might well be relied upon as a guide to dosage. He though that laryngeal cases were not apt to be so toxic unless other parts of the respiratory tract were also involved, and that therefore massive doses were not needed there.

Dr. WILLIAM PALMER LUCAS of San Francisco said that sufficient insistence had not been made upon the difference between the true Schick reaction and the pseudoreaction.

Dr. LAWRENCE T. ROYSTER of Norfolk, Va., said that he did not regard large doses as necessary in laryngeal and obstructive cases, and in cases in which there was muscular degeneration or atrophy of the myocardium large doses would do no good.

Dr. LANGLEY PORTER of San Francisco did not think a report of this discussion should go out as an authoritative opinion of the Section, for it was too indefinite. They should define what they meant by minimal doses, and they should not permit the statement to be published that the Section in Diseases of Children of the American Medical Association approved of the use of small doses of serum in the treatment of diphtheria.

Practical Value of the Examination of the Stools in Infancy.—Dr. H. M. MCCLANAHAN of Omaha, Neb., presented this communication in which he said that simple inspection of the stools gave much valuable information as to the color and consistancy of the discharges. The presence or absence of mucus and of blood curds, but a chemical analysis afforded additional information as to the digestion of fat and protein and it had consequently a practical application in the matter of feeding in difficult cases. He reported a number of cases illustrative of the value of a careful examination of the stools in infancy.

Dr. J. I. DURAND of Seattle said he did not regard the chemical and microscopical examination of the stools as a matter of very great importance in most cases. In the pediatric clinics of Berlin and Vienna no very great stress was laid on these examinations. It was generally possible to recognize by inspection alone which food elements were not being properly digested. It might, indeed, be important in teaching to demonstrate what could be learned by a use of the microscope and the test tube, but for the general practitioner inspection was more important.

Dr. C. G. GRULEE of Chicago said he was inclined to agree with the previous speaker that inspection of the stools was the more important as a routine measure. The object of an examination of the stools was to determine the underlying condition, whether something merely affecting the digestive tract or some essential disturbance of metabolism.

Dr. LANGLEY PORTER of San Francisco thought that certain chemical and microscopical examinations were of great importance. The gram stain, for example, was of value in showing an increase in the number of bacteria, and a chemical examination to determine the condition of starch digestion gave results of undoubted value.

A Clinical Study of Pneumonia in Infants.—Dr. HENRY DWIGHT CHAPIN of New York read this paper. He referred to the disappointing results of hospital treatment of pneumonia in children. His experience had been largely in the Post-Graduate Hospital which was located in a densely populated district where one could hardly expect to find much promising material, but the results were about the same in other hospitals dealing with cases of a similar class. The high mortality was due very largely to the poor vitality of these little patients and to the fact that many were not sent to the hospital until the disease was far advanced—often in the later and most dangerous stages. A large proportion of the cases represented secondary or terminal conditions which were apt to occur after any serious illness in poorly nourished infants. His paper was based upon a study of 50 cases, 23 of lobar pneumonia and 27 of bronchopneumonia. The lobar pneumonia cases gave a mortality of 21 per cent., the bronchopneumonia, 48 per cent. It was not always very easy to differentiate bronchopneumonia from lobar pneumonia. When the history showed a slow inception, form of a remittant type, not so constantly high, with disseminated patches over the posterior areas of both lobes, the case was considered as one of bronchopneumonia. In some instances both kinds of pneumonia were present in the same case. Hypostatic pneumonia was practically a terminal condition, Dr. Chapin said and was not usually recognized during life; it was almost constantly found up to 105° in atrophic babies. A notable feature of the series was that a high temperature was well borne. There was a notable leucocytosis in most cases. In some cases not showing a high degree of leucocytosis there was a high polynuclear average. The management of the cases was stimulating and supporting, the drugs employed being strychnine, caffeine, aromatic spirits of ammonia, and occasionally digitalis or nitroglycerin. For quick hypodermic effect camphor in oil and sodium-benzoate caffeine were depended upon. For cough and restlessness small doses of codeine sulphate as indicated was given. The drugs were always given singly. One of the greatest difficulties contended with was the giving of proper nourishment. Most of the children were already suffering from digestive disturbances arising from improper feeding before admission, and special treatment was therefore directed toward the digestive tract. This tested all the skill that the physician possessed. Vigorous infants with lobar pneumonia might respond well to fresh cold air but in the speaker's experience the cold-air treatment was not applicable in the bronchopneumonia of infants, but rather plenty of fresh air delivered into the ward moderately warmed. If better results were to be obtained in hospital treatment pneumonia cases must be admitted earlier and should be discharged as soon as resolution had taken place, since if they were kept too long there was danger of reinfection and relapse. Furthermore it was difficult to avoid secondary and cross infections when a number of weak infants were collected together in one place. Dr. Chapin's plan was to remove these infants to private homes in the country where provision could be made for supervision by a doctor and nurse as soon as the acute symptoms had subsided.

Dr. F. C. KNEFF of Kansas City emphasised the importance of proper feeding in these cases of pneumonia in children, since one of the greatest dangers in this disease was that of digestive disturbances.

The Problem of Unresolved Pneumonia in Children.—Dr. WILLIAM LUCAS of San Francisco read this paper in which he called attention to this condition as being not infrequent in hospital practice. It called for careful differential diagnosis as it was apt to be mistaken for tuberculosis or possibly beginning empyema. Fluoroscopic examinations and thoracentesis repeatedly performed were necessary to clear up the diagnosis. In these patients the pneumonia might not entirely clear up for months, but if they were treated as tuberculous patients many would recover unless some intercurrent infection supervened. Dr. Lucas exhibited a number of *x*-ray pictures and described several cases in which the diagnosis had been determined by their help.

SECTION ON SURGERY, GENERAL AND ABDOMINAL.

DR. CHARLES H. PECK OF NEW YORK, CHAIRMAN.

Tuesday, June 22—First Day.

Chairman's Address.—Dr. CHARLES H. PECK of New York delivered this address, taking as his title, "Bang's Lesion of the Stomach and Duodenum, with Special Reference to Late Results." The paper was based upon a review of the cases of gastric and duodenal ulcers coming under observation in Roosevelt Hospital during the past five years. The beneficial effects of gastroenterostomy in these cases were due, he said, either to the changed chemistry of the stomach or to the drainage afforded by the operation—probably to the drainage. Dr. Peck recommended simple gastroenterostomy for duodenal ulcer, gastroenterostomy with excision of the ulcer for gastric ulcer. The mortality of chronic duodenal ulcer was 8.1 per cent., this estimate being based upon a study of 58 cases. Seven patients of 13 suffering from gastric ulcer were reported well 5½ years after operation. Out of 17 cases of acute perforating ulcer, 15 made operative recovery, and 13 were permanently cured. The speaker said that both clinical and radiographic signs pointed to continued potency of the pylorus and a functionating stoma.

Chronic Gastric Ulcer.—Dr. WILLIAM J. MAYO of Rochester, Minn., presented this communication. He said that gastric ulcer was a more serious, but fortunately less frequent condition than ulcer of the duodenum. The chief reason for this greater degree of seriousness was the danger of perforation and leakage of the more toxic stomach contents. A predisposition to gastric ulcer was afforded by the deposit of excessively hot or excessively cold food in the pyloric portion through the canalis gastricus. The speaker said that he saw no advantage to be gained in closure of the pylorus in cases of gastroenterostomy. He believed that caudad section of the stomach for lesions in this region of the organ gave better results as regarded gastric motility.

The Relation Between Chronic Ulcer and Cancer of the Stomach.—Dr. A. J. OCHSNER of Chicago presented this communication. In all cancers, he said, the growth was located on the edge of the ulcer except in the case of papillanata. The ulcer-bearing area was similar to the seat of greatest frequency of gastric cancer. To reduce the frequency of cancer of the stomach we should preach the avoidance of sudden changes of temperature of the gastric mucosa and of the taking of uncooked food, for the speaker believed the cancer germs reached the stomach in the food. For the preservation of life early diagnosis leading to early operation was essential.

Dr. EMMET RIXFORD of San Francisco pointed out the difficulty of an absolute diagnosis early in the course of malignant disease of the stomach.

Dr. WILLIAM L. RODMAN of Philadelphia urged the necessity of excision of all ulcers of the stomach in order to avoid the dangerous consequences of these lesions. These were perforation in 33 per cent. of all cases and hemorrhage, with or without perforation, in 50 per cent. In 60 per cent. of all ulcers, if untrastal, malignant growths developed.

Dr. W. I. TERRY of San Francisco questioned the alleged frequency of cancer of the stomach; and other speakers discussed the causative factors of malignant disease.

Röntgenological and Surgical Aspects of Gastrojejunal Ulcers.—Dr. R. D. CARMAN of Rochester, Minn., reported a series of cases of gastrojejunal ulcers following gastrojejunatomy. He said the ulcer should be excised and gastroarterostomy should be performed if much induration was present.

Surgical Anatomy of Cleft Palate.—Dr. J. RILUS EASTMAN of Indianapolis read this paper. He dwelt upon the necessity of care in the operation to avoid the ascending posterior palatinoastomy, and emphasized the importance of detaching the border of the soft palate from the hard palate.

Dr. Harry Sherman of San Francisco said he had experienced the greatest annoyance, in operating for the closure of cleft palate, from the difficulty of controlling the action of the tensor palate muscle, and he had also had much trouble from infection of the wound.

Ileocolostomy and Colectomy for Arthritis Deformans.—Dr. Rea Smith of Los Angeles, in this communication, reported a series of cases which supported the contention of Davis and others that arthritis deformans was chiefly or very largely of intestinal origin, being one of the manifold results of autointoxication.

Dr. James F. Percy of Galesburg, Ill., referred to the buccal origin of arthritis deformans, which was, he though, of as much importance and as frequent as the intestinal origin.

Myositis Ossificans Traumatica.—Dr. Oscar M. Shere of Denver read a paper with this title, in which he stated his belief that the affection occurred with greatest frequency as the consequence of a single closed injury. He discussed the surgical pathology of the disease and its treatment from the standpoint of sarcoma.

Dr. Dean De Witt Lewis of Chicago said it would be interesting and of the greatest importance to determine the frequency with which myositis occurred after the receipt of an injury.

Dr. Alexius McGlannan of Baltimore advised an expectant course after an injury waiting to see what happened. No operation was indicated if the bone shrank, which, in his experience, was what usually happened. Operation during the acute inflammatory period following the trauma was very apt of increase bone proliferation.

ELECTION OF OFFICERS

The following officers were elected by the House of Delegates on Thursday, June 24:

President, Dr. Rupert Blue, U. S. Public Health Service.

First Vice-President, Dr. Edgar A. Vander Veer, Albany, N. Y.

Second Vice-President, Dr. George B. Evans, Dayton, Ohio.

Third Vice-President, Dr. Donald Campbell, Montreal, Canada.

Fourth Vice-President, Dr. Herbert C. Moffitt, San Francisco, Cal.

Secretary, Dr. Alexander R. Craig, Chicago.

Treasurer, Dr. William Allen Pusey, Chicago.

Trustees, Drs. M. L. Harris, Chicago; William T. Councilman, Boston; Thomas McDavitt, St. Paul.

The next annual session will be held at Detroit, Mich.

(*To be continued.*)

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held April 23, 1915.

The President, Dr. Howard Lilienthal, in the Chair.

Medical and Surgical Aspects of Empyema of the Thorax, with Conclusions Drawn from a Study of 299 Cases.—Dr. Abraham O. Wilensky read this paper which gave the results of a study of 299 cases of acute and subacute empyema, these being all the cases treated at Mount Sinai Hospital in the last ten years. Of these there were 285 cases of acute empyema, six cases of tuberculous empyema, seven of pyopneumothorax, and one of actinomycotic empyema. One-third of the cases were under two years, two-thirds were under ten years of age. Sixty per cent. were males and 40 per cent. were females. Eighty-three per cent. followed some affection of the lungs or pleura; 11 per cent. were primary. Besides these, empyema had followed the infection diseases, had been metastatic, and had followed trauma. Sixty-six per cent. were metapneumonic. Tuberculous processes rarely led to suppuration within the pleural cavity. The pathology of general, localized, and interlobar empyemata were described. The character of the effusion was gone into in detail, also the bacteriological and blood culture studies. The importance of operating at the right time was emphasized. Treatment included aspiration, intercostal incision, and thoracotomy with rib resection. All the complications were gone into and it was pointed out that these accounted for most of the deaths. The essayist found that 53 per cent. were cured after the primary operation; 28 per cent. died; 12 per cent. were improved; seven per cent. were not improved. He concluded as follows: (1) In the great majority of the cases empyema was secondary to some other inflammatory lesion in the body. (2) The mortality for the series was 28 per cent. varying from 50 per cent. in children to 18 per cent. in adults. (3) The most favorable period for recovery was between 3 and 10 years of age. (4) Twenty per cent. of the patients died as a result of the primary illness, or of a recurrence of it, or of some other complication or intercurrent disease. Only 8 per cent. died because of the process in the chest. (5) Twenty-three per cent. of the patients that recovered had more or less trouble with the healing of their sinuses. (6) Advances to be made in the treatment of empyema would come from improvement in the operative technic or in in the after-treatment, which would tend to decrease the frequency of chronic sinuses to a minimum or perhaps to eliminate it altogether.

Dr. Charles N. Dowd said that it was a pleasure to hear empyema of the thorax referred to as a secondary disease. It was very commonly treated as the primary disease and attention was given to the pleura which might better be given to the lung. Pneumonia was usually the primary disease and pyothorax was a complication. The pneumonia continued its wandering persistent course and was really much more dangerous than the pus collection. The liberation of the pus was a simple matter and should not be treated as a major operation. The giving of a general anesthetic to a patient who had pneumonia was to be avoided, if possible, and it was usually unnecessary for these patients. A preliminary dose of morphine followed by the local injection of one per cent. solution of novocaine gave local anesthesia which was ordinarily sufficient. A piece of rib could usually be thus resected. If it were really necessary the local anesthesia could be supplemented by a very short use of nitrous oxide. It was usually advisable to insert the finger into the chest so as to determine the degree of lung compression and to remove the coagulæ. If the patient coughed and expanded the lung at this time the danger of persistent fistula was practically past. It was particularly desirable that every procedure should be adapted to the patient's condition; the removal of the coagula in order to secure immediate expansion of the lung was desirable, but if the patient was not able to stand the measures which were necessary to obtain these results, drainage might be secured through an incision between two ribs. If the temperature rose a few days after the drainage was established, undrained pockets of pus were often suspected and vigorously searched for; they seldom existed. Dr. Northrup in making a very large number of autopsies at the Foundling Asylum never found one. Pneumonia was the most common cause of such temperature rises. In a recent paper before the State Medical Society the speaker said he had referred to twenty-three autopsies on empyema cases, and in almost all of these death was due to pneumonia or a pneumococcus complication. If there was a collapse of the lung Dr. Lloyd's suggestion was a good one, to break up the adhesions and thus endeavor to obtain lung expansion. In those cases in which the lung refused to expand a major operation was desirable. Among the 285 cases of empyema which he had reported there were 19 who had persistent sinuses owing to lack of lung expansion.

Dr. Samuel Lloyd said that this question had interested him for many years. He recalled that when he was at Princeton University the Professor of Biology was also interested in this work and he told him to take a cat, board and play with cats, studying the cases, etc. He placed a plug of cotton in a cat's chest during these series of experiments and found that the cat expanded the lung. Soon Dr. Lloyd forgot all about this experience. Later at the Randall's Island Hospital he met with many cases of empyema of the chest which bothered him and then he recalled the experiments made with the cats at Princeton University. He discovered that if they used a low anesthesia, allowing the patient to gradually come out of the anesthesia, when the patient coughed the lung would begin to expand, not with inspiration, however, but with forced expiration. Dr. Smith had likened this to the working of a pair of bellows. Dr. Lloyd said he did not advocate the operation today as he did years ago where the lung was not

already bound down by adhesions, but only in those cases where the lung was compressed and already bound down in the pleural cavity. In cases of acute empyema where the lung was not bound down, the operation formerly advocated by him was not now indicated. Where it was impossible for the lung to expand he advised giving low anesthesia and breaking down the adhesions. They had found that the mortality in these cases was greater in the younger children. He had found that the pneumococcus cases gave a better mortality; he dreaded the streptococcus cases which gave such a large mortality. In the pneumococcus cases one should operate early and many of them would get well. All these cases should be recognized earlier than they were. When there was fluid in the chest one should operate, in his opinion, early before the fluid became purulent. Every case with fibrin deposit should be thorocotomized. The mortality differed year by year. The main point he raised was that these cases should be operated upon early and thus the necessity of an extensive radial operation would be avoided. A second point was that an incision should be made into the chest in those cases in which the lung refused to expand and come down. The third point was to break up all adhesions and so allow the lung to expand. The apex of the lung must be released. Then too, they must be able to recognize an unresolved pneumonia. All lung abscesses should be drained at the time the operation on the empyema was done.

Dr. Henry Koplik said that it was unfortunate that these statistics were taken from hospital cases. It was true that many of these cases developed in the hospital, but most of them came to the hospital in bad or moribund condition, and therefore to the general practitioner hospital statistics are always misleading. The results in private practice would be more encouraging. Speaking of the prognosis, it would be seen at once that the age of the patient was a great factor. The mortality below one year of age was highest; that below two years of age quite high, and as had been pointed out, the best prognosis was given between the ages of five and ten years. The reason of this was quite evident to those who would analyze the cases. In children under one year of age, especially, the nature of the infection was that of a bronchopneumonia, limited or diffused on both sides. An empyema in such a case gave a serious prognosis, because the case had been operated upon, as a rule, before the bronchopneumonia had run its course. The result was that the lung collapsed when the chest was opened, and in a collapsed lung, the bronchopneumonia rarely cleared up, and the patients ran a course of temperature, with a large suppurating pleural cavity, and died of exhaustion. Above two years of age the infection was that of a lobar pneumonia. Here the resistance was not only greater, but was due to the advanced age. When the patient was operated upon, the pneumonia, as a rule, had run its course, the lung did not collapse, and the patient recovered simply because the pus was evacuated from the chest; therefore, the nature of the infection, as well as its severity in the relationship mentioned, was a potent factor in the prognosis. The condition of the patient at the time of operation was very important. A patient in a weakened condition should be tidied over by aspiration until the conditions were favorable to a more radical procedure. This was especially true of young, weakly babies. The operator also should not commit himself to one operation for all cases. The speaker said he had seen a baby of nine months of age, weighing, say, ten pounds, on whom the surgeon performed an operation by resection, as he said, to get perfect drainage, with the result that the patient collapsed after the operation, and died as a result of the radical procedure, whereas a simple incision in the chest might have saved the little one. Dr. Koplik doubted very much whether the prognosis could be predicted from the bacteriology of the fluid. It was not known generally that clear serous exudates contained pneumococci and streptococci. He referred to those exudates of pleurisy which got well without any interference except aspiration. He had always imagined that the practitioner was too eager to operate early in empyema. As soon as a turbid fluid was discovered the practitioner was anxious to place the case in the hands of the surgeon. He preferred to wait, in bronchopneumonia, especially of young children, until the temperature had dropped, and the fluid had become definitely purulent, before operating. In lobar pneumonia, it was much better to wait until the disease had run its full course, and a definite collection of purulent fluid had taken place before operating. For in these cases, as he had intimated, the pneumonia having run its course, the lung expanded more readily after operation, than when the chest was opened with foci of pneumonia still in the lung.

Dr. L. Emmett Holt said that the child as well as the empyema of the thorax must be considered. Few children under one year of age could stand an extensive operation. The great difficulty encountered in these small children was not that of drainage but that of obtaining proper lung expansion. He cautioned against the use of general anesthesia in these operations and also against excessive manipulation. He advocated for very young infants the siphon method of continuous drainage. In his experience the cases due to the streptococcus and to mixed infections were the most serious while the pneumococcus cases gave much better results. The staphylococcus infections in young infants gave the best prognosis. Many children were benefited by deferring operation until the acute pneumonia had subsided. Sex incidence in these cases was quite striking. There were in 204 empyemas of the thorax, 140 males and 64 females. This difference could not be satisfactorily explained. Pneumococcus meningitis caused death in five of this series of cases; also there were eight deaths attributed to suppurative pericarditis. In the great majority of cases the cause of death was the pulmonary condition.

Gallstones.—Dr. Beverley Robinson read this paper in which he stated that they were constantly meeting people who had passed middle life who gave premonitory symptoms of gallstones which if properly heeded might prevent later troubles. Among these symptoms were nausea and vomiting after a meal in which some food rich in fat had occasioned the upset, or a sudden diarrheic attack. With these manifestations there was often much chilliness or a feeling of faintness. Certain surgeons, notably Moynihan and Chauffard, had insisted that these and other symptoms usually assigned to the stomach were undoubtedly caused by the presence of gallstones and indicated the need of active interference by the surgeon. The question arose as to how such patients should be treated when their advisors did not share these radical views. If the patient was a man or woman of small means who was unable to be absent from daily work, and, if after several weeks of intelligent and careful treatment the dyspeptic symptoms remained, or were aggravated, or one or more attacks of biliary colic had supervened, it would seem injudicious to postpone an operation. But if the patient was well-to-do it was different. Medical treatment continued at home or abroad at a spa would not usually cure, but it would make the annoying symptoms far less for weeks and months and might prevent the outbreak of another attack of biliary colic. Under such conditions a diet including a variety of flesh food, broiled or roasted might be allowed and most vegetables were permissible, but alcoholic drinks must be forbidden and fats and sugar should be interdicted as far as possible. Frequent small meals were desirable. Laxatives and frequent small doses of calomel were useful. Daily exercise in the open air should be insisted upon. No doubt the alkaline salt sulphate of soda in Carlsbad water, as well as the hot liquid, helped to liquify the bile. Where there was a suspicion of infection of the bile moderate doses of salicylate of soda, or urotropin, should be given regularly for some days. When attacks of intermittent fever with chill occurred, similar treatment with the addition of hot stupes had a good effect. The formation of gallstones might largely be prevented by a carbohydrate diet. Dr. Robinson said he did not believe that remedies said to promote the flow of bile such as calomel, podophyllin, iridin, etc., had practically demonstrated their value, neither could it be said that olive oil was of value when one realized the improbability of its coming into direct contact with the gallstones. It must be understood that no medical treatment would effect an absolute cure of gallstones, but it might possibly soften them and diminish their size somewhat. The *x*-ray had its limitations as a means of revealing the presence of gallstones, though the technique had been improved so that they were recognized more frequently than formerly. While admitting the advisability of not waiting too long before resorting to surgery, the writer deplored all operations on the gall-bladder done by incompetent hands. He cited cases in his experience which led him to avoid as far as possible obtaining even skilled and careful surgery. He discussed the need of very careful judgment with reference to the advisability of operation, especially since even the most skilled surgeons were at variance

as to the exact indications for operation and recognized two types of cases: those with vital indications and those with relative indications. Among the remedies which had been mentioned favorably as to their action on the liver, perhaps even helping dissolve biliary stones were the bile acids, bile itself, boldine, schonanthin, and sodium succinate. In the writer's judgment nothing in the way of preventive or curative medical treatment met with similar successful result to that which might be had at Vichy, Carlsbad, or Hamburg, though he said he had seen much harm done by too enthusiastic practitioners and patients by too long drinking of the water at the spa, and also by too rigorous dieting. Nothing in the way of medicinal treatment was sovereign in any case, and the value of the personal equation must always be carefully considered. In the interval of attacks of cholecystitis, with or without gallstones, Dr. Riesman usually prescribed the following in capsule three times daily: Sodium salicylate, sodium succinate, ox-gall, each two and one-half grains. A fact to be emphasized was that in the judgment of the men of largest experience gallstones did not recur. After considering somewhat more at length the dangers of rushing inadvisedly into an operation, Dr. Robinson noted with satisfaction the drift toward saner thinking and doing, and said he thought the return should be to the old position when the physician took charge of the patient throughout the whole course of the disease and only invoked the surgeon's mechanical talent on those occasions when it was evidently required.

The Diagnosis and Treatment of Cholecystitis.—Dr. ANTHONY BASSLER presented this communication. After briefly referring the physiological function of the gall bladder he expressed the opinion that Luschka's crypts were potentially pathological, occurring as a development in chronic cholecystitis. He said it was interesting from a clinical standpoint to note that every process of the appendix occurred in the gall bladder—catarrhal, ulcerative, hemorrhagic, pseudomembraneous, phlegmonous and gangrenous. Even the chronic fibrous and obliterative appendix had its counterpart in the gall bladder. This was important to remember when one recalled that disease of both of these organs was so commonly met with at the same time and that it was so difficult to make a differential diagnosis between them. They could now all agree that cholecystitis was due to bacterial infection and that this infection reached the gall bladder with the bile directly from the liver which acted as an organ of body drainage, evicting bacteria from the general portal system. The most frequent association of cholecystitis was with gallstones, which occurred in the sequence of infection, stagnation and precipitation. While in a clinical sense gallstones were the most important factor in bringing out cholecystitic symptoms, one must not forget that such symptoms could occur without gallstones being present. They had seen the instances of typhoid fever, septicemia, pneumonia, food poisoning, and almost all infections in which it did occur in an acute manner. It was wise when a prolonged dyspepsia and tenderness existed that one should not diagnose "gallstones." It was better to say "an inflamed gall bladder," or, as was the author's choice, "pathology of the gall bladder." In a case in which the symptoms had been standing for some years, the history of infection was distinct, and the symptoms came on soon after this infection, one might be bold enough to say "cholecystitis with stones." In such an instance they were commonly present though not always. The gall bladder in chronic cholecystitis might be large and filled with foul smelling bile; or it might be normal in size and slightly thickened, containing bile in an infected mud; or it might be small, thick walled, whitish, and shrunken, containing a thick bile. More interesting, however, was the strawberry appearance of the mucous membrane in which one saw a dotting over of tiny yellow specks. This, in the author's opinion, was the most characteristic pathology, and warranted surgery whenever met with. Empyema of the gall bladder rarely occurred without stone and was most likely to occur in the impacted stone cases. As an acute condition it was one of the most fulminant, ending in a few days in rupture of the gall bladder and general peritonitis. Less severe cases presented the symptoms of a localized peritonitis. The case again might be less like a peritonitis and more like a biliary colic, when one met with fever, accelerated pulse, vomiting, leucocytosis, and rarely jaundice. In this type of case there was not much spasm of the abdominal muscles over the gall bladder but if the warmed hand was laid flat and gently on the abdomen one might feel the distended gall-bladder underneath. If one examined directly with the tips of the fingers one was not so likely to feel it, or an indistinct mass was felt continuous with the right lobe of the liver too closely simulating a Kiedel lobe to be sure either way. At operation such a gall bladder was found tense and distended with a mucopurulent fluid free from bile. Phlegmonous and gangrenous cholecystitis could not be differentiated clinically from the suppurative. They usually gave more severe symptoms than empyema. The acute forms of cholecystitis could readily be mistaken for appendicitis, since the pain might be referred to the right lower quadrant. Another type of cholecystitis might simulate uremia. Dr. Bassler spoke particularly of the diagnosis of common cases of cholecystitis in which gallstones might or might not be present, since these made up a considerable proportion of the cases which he saw in his office work and in too few of which diagnosis were being made. There were many having chronic cholecystitis in which the symptoms were entirely dyspeptic in the subjective way. They differed but little from the condition met with in chronic appendicitis, the history being quite as long. As an aid in making a diagnosis there were three procedures of physical examination that were distinctly helpful, the sign described by Robson and two which the author himself employed. The Robson point was tenderness on deep pressure midway between the tip of the right ninth costal cartilage and the umbilicus. The lower border of the liver being so variable in its position in the abdomen, this sign could not be depended on invariably. Dr. Bassler suggested that instead of making point pressure the ulnar side of the extended hand be pressed between these two points along the entire distance. If the tips of the fingers could be impinged under the ribs, the ulnar side of the hand could be pressed over the ducts as well and since these were tender sometimes the value of the sign was enhanced. The first of the author's signs was practised as follows: The position of the lower edge of the liver was carefully mapped out by superficial and gentle palpation and the tips of the fingers of one hand were sunk deeply directly below it in the gall bladder region. On deep inspiration the liver was driven against the maintained position of the tips of the fingers causing distinct pain. It was important that the gall bladder be pressed between the tips of the finger and the liver and the median fissure helped to guide one. The second sign was somewhat the same and was particularly useful when the liver was high or small. Here the examiner sat behind the patient, allowing the patient to rest back on his left shoulder to relax the abdominal muscles. The palmar surfaces of the fingers of each hand were then sunk firmly and deeply under each costal arch until the tips of the right were under the gall bladder and that of the left well over the stomach. Pressure was made alternately on one side and then on the other, first under condition of diaphragm rest, then under inspiration. Using the left side as a control, a tenderness in the gall bladder region was most suggestive. The author said he could not speak too enthusiastically of these two signs. Dr. Bassler, after speaking of the uncertainties of making a diagnosis of gallstones with the *x*-ray and reviewing the well established method of treating cholecystitis, advised the use of the following prescription:

Acidum soda oleat.	
Sodium salicylic	aa 4.3
Phenolphthalein	1.0
Mentholis	.35

Fiat. Pil. No. 50.

Sig. Two before breakfast and before retiring.

Such treatment merely brought about a *status quo;* no dissolving of gallstones took place. When the symptoms were frank enough, did not respond to medical treatment, or returned quickly, operation was indicated. It was likewise indicated in empyema of the gall bladder, diabetes, and cancer, and, of course, when phlegmonous or gangrenous cholecystitis was suspected. One might advise conservatively in individual instances but, in the author's experience, in view of the low mortality at the present time operation was far better for the patient and fairer to their knowledge of the subject. He believed with Mayo and Deaver that if more of those patients who did not respond early and definitely to medical treatment were operated upon, the reaping of the unfortunate sequelæ of cholecystitis would not be as marked as it was today.

Dr. JOHN HARTWELL said that he desired to discuss only one phase of the question, and that had to do with the surgical treatment of cholecystitis and gallstones. He felt that in this matter the responsibility for deciding on operation should be borne rather more by the surgeon than by the internist. The internist who considered the surgeon simply as a technician to carry out his instructions, failed to get from the surgeon the aid to which the patient was entitled. No surgeon who trained himself along only the lines of operative dexterity was capable of undertaking operations for diseases of the gall bladder. The functions of the internist and the surgeon did not differ until the time arrived for the application of therapeutic measures. The surgeon, therefore, must be equally familiar with all the details of the disease's process, must understand as fully as the internist the details of non-operative treatment, and the probability of success in both this and the operative treatment. Only in this way did the surgeon place himself in a position to do full justice to his patient and his art. In deciding for or against operation in a condition such as gall bladder disease, where remissions and recurrences were the rule, the question of first consideration was what was the relative danger of the disease, and of the operation. In other words, granting that the immediate condition could be controlled by internal medication was there a probability that a recurrence would occur which would demand operation as a life saving measure under most unfavorablable conditions for such an operation? This was the situation which presented itself to the internist and the surgeon in every case of gall bladder disease, and since the operative responsibility rested with the surgeon it was only fair that his opinion should carry great weight in deciding for or against operative interference.

NEW YORK NEUROLOGICAL SOCIETY.

Regular Meeting, Held Tuesday, February 7, 1915.

THE PRESIDENT-ELECT, DR. W. M. LESZYNSKY, IN THE CHAIR.

Case of Deformity of the Skull with Optic Atrophy.—Dr. L. SHAPIRO presented this case which was admitted to Mt. Sinai Hospital by Dr. Sachs five weeks previously, with symptoms of chorea, associated with marked deformity of the skull and optic symptoms. The boy was 13 years old, of Russian parentage; the father had somewhat abnormal changes of the skull with prominence over the frontal region, but no optic symptoms; the child had a normal birth and no peculiarity of the skull was noted; later the mother observed the eyes becoming more prominent and the peculiar shape of the head became evident; five years ago the boy had scarlet fever, complicated by severe nephritis and hematuria and generalized edema; after this he could not longer see and the blindness was attributed to the scarlet fever; before that he was perfectly well; after that the unusual height of the skull, increase in breadth at the temporal region, and abnormally low ears became noticeable; this was no doubt due to premature ossification of the sutures of the vault which interfered with the normal expansion of this portion of the skull; the *x*-ray showed a peculiar net-work of thinned out areas in the frontal region; this was due to absorption of the inner table of the skull, as had been shown at operation; as to the nature of this premature ossification, it had been observed that this condition had been noted in the ancestry of these cases and Carpenter had noted a case where four children in one family showed a similar condition; other congenital malformations were frequently present, such as congenital pulmonary stenosis and cyanosis of the face; ventral and abdominal herniæ, webbing of the fingers, polydactilism, etc. One case of dermoid cyst had been observed; this association with other congenital malformations and in family groups might argue for congenital origin; the *x*-ray pictures showed enlargement of the pituitary fossa; this had been interpreted as being due to change in the pituitary gland which by some action caused dystrophy; this patient had no other symptoms than ocular ones associated with deformity of the skull; the oxophthalmos was evident; the right eye bulged more than the left; there was no nystagmus; in some cases dislocation of the eyeballs occurred; impairment of function in these cases was due to optic atrophy following neuritis; the origin of this neuritis was not well understood; because of the optic symptoms in this group of cases they were first observed by ophthalmologists. Von Graefe in 1866 had recorded cases; some views as to the cause of the optic neuritis had been advanced; Virchow considered it due to meningitis at the base of the brain, which caused neuritis and subsequent atrophy; other views were that it was due to the abnormal course of the internal carotid, the pressure causing atrophy; or, it might be occasioned by stenosis of the optic foramen which caused pressure and optic atrophy; perhaps the cause might be the difference between the size of the skull and the growth of the brain and the consequent increased cerebral pressure; lumbar puncture was done in this case and there was no increase of pressure; optic atrophy when it occurred, usually occurred before the 7th year, because the greatest growth of the brain was before that age; it was more frequent in boys than in girls and more common in dark-complexioned, sallow individuals; this boy had an organic heart lesion, due to several attacks of chorea; he was an intelligent boy, not at all mentally deficient.

Dr. FOSTER KENNEDY said that these cases were sufficiently rare to deserve consideration. Dr. Shapiro had given a very complete presentation. One point which interested him was the reference to the optic nerve changes in these cases. Dr. Shapiro said the atrophy was of a consecutive character, following neuritis. Dr. Kennedy was not sure whether he meant papilledema or retrobulbar neuritis. The question of the pathology of the exact processes occurring in these cases was important in view of the uncertainty as to the processes which produced changes in the optic nerve. In one case studied the optic nerves were found to be white, in another pallor was present in the temporal region. That would point to the fact that loss of vision was not due to papilledema. It might be produced by pressure of the bony ring on the nerve, a process analogous to the pressure produced by sinusitis and by frontal tumor.

Dr. ABRAHAMSON said the interesting point in the disease was the causation of the fundus changes. Internal hydrocephalus failed to explain them in very many cases. Enslin in 42 cases found twice double neuroretinitis, twice papilledema on one side with neuritic atrophy on the other; twice an apparent primary optic atrophy; thirty-six times post-neuritic atrophy. Cases were reported of oxycephalus with open sutures except the coronal and open fontanelles; with congenital meningoceles; with changes in the eye grounds essentially on one side. The problem was very important since it determined whether decompression or callosal puncture was advantageous as Anton had suggested. Behr believed that the narrowing of the optic canals and the bony dislocation with displacement of the internal carotid artery and compression of the optic nerve by the pulsating artery, were the important factors. The gradual concentric diminution of the visual fields found could also be explained that way. Central scotomata, as in Dr. Kennedy's case, were rare.

Syphilitic Muscular Atrophy.—Dr. JUNIUS W. STEPHENSON presented this case. The patient was a married man, aged 42, who denied all venereal infection, but admitted excessive use of alcohol for 15 years. He was the father of two children; his wife had no miscarriages. History antedating present illness was uneventful. Eighteen months ago patient had noted a weakness of his left hand which had progressed rather rapidly for several weeks, after which he stated that it had remained stationary. About six months following this the right hand was attacked in the same manner and progressed quite rapidly for a period of several weeks when it became stationary. There was no pain or paresthesia. Physical examination revealed double drop wrist with wasting of the thenar and hypothenar eminences, more marked in the left hand; also there was considerable wasting of the interossei more marked in the left hand; extensors of both wrists were very weak, causing a double drop wrist. There was a slight thinning of the left deltoid. The right knee jerk was present but very sluggish; the left was questionably elicited under reinforcement; ankle jerk was not elicited. Plantar, flexor, abdominal, and epigastric reflexes were active and equal. There were no sensory disturbances. Pupillary mobility was good; no nystagmus or diplopia. The right pupil reacted somewhat slowly to light; the left fairly; there was a slight irregularity of outline. There had been a perforating ulcer under the right great toe of one year's duration and patient stated that five or six years ago he had "perforating ulcers" under both great toes which were

said to have responded to treatment; inconstant fibrillary twitchings had been observed. Electrical reaction of the atrophied muscles was as follows: muscles of thenar eminence of left hand showed very slight responses to full faradic coil CCC = ACC. The other muscles of left hand showed slight hyperexcitability to faradism; galvanic o.k. Muscles of right hand responded to increased amount of both currents, left shoulder normal. Serum Wassermann positive; spinal fluid Wassermann positive; no globulin excess; 28 cells per c.mm. reduced Fehling's solution. Uranalyses negative and blood negative for lead findings. The clinical course and serological findings, Dr. Stephenson said, left no doubt as to the diagnosis of this case, which he presented as a muscular atrophy of luetic origin, the pathology of which, though not as yet universally accepted, was probably luetic endarteritis with thrombosis of the anterior horn vessels. Of course the condition of the various reflexes also indicated posterior column involvement, and the case might be considered as a case of tabes with atrophy, but the clinical course was so characteristic of the condition described by Dr. Dana as syphilitic muscular atrophy in which he recognized a distinct neurological entity, that the present case was presented as an example of it.

Dr. Foster Kennedy said he thought cases of atrophy in the hands associated with systematic changes in the spinal cord were not exceedingly uncommon. There was an alternative pathology. The case might be one of tabes with a well marked annular constriction which had produced nipping of the roots of the cervical nodules, or a premature degeneration of the tissue of the anterior horn. One saw occasional cases of tabes in which there was well marked muscular atrophy in the hands. He had seen one case with such hands, with present ankle jerk, no knee jerk and double extensor responses. This would be accounted for by pressure in the cervical region by hypertrophic meningitis.

Dr. S. E. Jelliffe said he would be inclined to think that this patient was allied with the group of tabetic cases described by Déjerine. Probably, from the disruption of ulcers in the lower limb, it was an acute radicular type of tabes.

Dr. Stephenson said he saw a similar case a year ago presenting the atrophy with no change in the jerks or pupils who, about three months later, developed a typical picture of tabes. There had been no pain, nor had they been able to elicit any sensory disturbance of any nature. The cases of pachymeningitis which he had seen had all presented pain and spastic phenomena. The case here shown presented flaccid findings without pain, therefore he thought we could eliminate the condition known as pachymeningitis. As stated the case might be considered tabes with atrophy but he preferred to assume that the initial lesion was a vascular one affecting the anterior horn, and that the patient was now developing a posterior column degeneration.

Basedow's Disease Treated by X-Rays.—Dr. A. Polon made this presentation. The seven cases presented came from the out-door service of Dr. I. Abrahamson, at the Mt. Sinai Hospital, and were treated by Dr. Polon with Roentgen rays at the department of radiotherapy of the same institution. The cases chosen belonged to the clinical groups classed as hyperthyroidism and morbus Basedovi. All of the cases had goitrous enlargement. The rationale of this theraupeutic procedure, Dr. Polon stated, was based upon the biological phenomenon that glandular tissues were inhibited in function and growth, and were even caused to atrophy by the radiation emanating from an *x*-ray tube. The method used presented a modification of the one commonly in use, in that the dosage administered was usually massive, applied at frequent intervals, the ray being of high penetrating power and filtered through one or two mm. of aluminum. The working formula was as follows: distance of nearest point of skin from anticathode 20 cm., miliamperes 6, spark gap 15 cm., time of exposure 3 minutes, filter 2 mm. with the usual protection of skin from the secondary filter radiation, interval between treatments 14 days. The Coolidge system used permitted of exactness and constancy of dosage. The patient was placed in reclining posture, the thyroid region being divided into two or three parts, each being rayed separately while the others were protected. Treatment of about 35 cases of hyperthyroidism and morbus Basedovi with goitrous enlargement, of which seven cases were presented, permitted of the following conclusions: (1) the size of the enlarged gland was definitely diminished by Roentgen-rays; (2) the diminution in size was commonly associated with an amelioration of all the symptoms, especially in early and mild cases; (3) uncommonly a diminution in size of the gland might be effected without a change in the general symptomatology; the shrinkage of the thyroid could not be ascribed to ensuing myxedema, since the Basedow symptoms persisted; (4) the course of the disease was not aggravated by the treatment even in these cases in which no change in the gland was observed; (5) the application of the ray did not preclude, nor did it interfere with other modes of treatment; (6) cases refractory to surgical, serological, gland feeding and drug therapy were benefited by Roentgen therapy. The main features of the cases presented were as follows:

Case I.—Thirty-six years; hysterectomy six months; ever since pronounced symptoms of morbus Basedovi; marked enlargement of thyroid; circumference measurement 15.5 inches; insomnia; psychic disturbance; anorexia; loss of weight; tachycardia 120; since December 9, four massive treatments; improvement at present in all signs and symptoms; glandular circumference diminished by one inch; sleeps well; gain in weight; pulse rate 90; improved mental attitude; still under treatment.

Case II.—Seventeen and one-half years; female stenographer; duration one year; tachycardia; palpitation; exophthalmos; tremor; prominence of isthmus; treated from June 20 to July 25, four times, two full, two half doses; pulse now 84; feels well; thyroid diminished; continues work past six months.

Case III.—Male, more severe case; 21 years; post-office clerk; onset after severe scarlet fever; came to clinic February 5, 1914, complaining of intense precordial pain, palpitation, weakness, irritability; measurement of thyroid anteriorly 15 inches; pulse 110; von Graefe +; Moebius +; received 10 treatments between February 5 and March 11, representing five massive doses; amelioration of symptoms; gland diminished 1 inch; pulse 80; gained 10 pounds weight; not been at clinic since March, 1914; has been working since. This is one of the few cases that show improvement after exophthalmos has been established.

Case IV.—Female 39 years; duration 1 year enlargement of thyroid; tachycardia; tremor; moderate exophthalmos; received four massive doses since December 5 last year. Improvement in all signs and symptoms including diminution of thyroid measurement from 14.5 to 13.5 inches.

Case V.—Female, 28 years; persistent enlargement of gland with pressure symptoms 2 years; all other signs of Basedow's; 3 treatments since December 26, 1914. Amelioration of all symptoms including diminution in size of gland.

Case VI.—Female, 32 years; operated upon thyroid 2.5 years ago; followed by all signs of unfavorable Basedow's; gland continues to enlarge in spite of intensive raying; 8 massive doses in 3 months.

Case VII.—Female, 39 years; 22 months duration before treatment; glandular enlargement, tachycardia; nervousness; 6 massive treatments between July and December, 1914; symptoms at this date, slowing of pulse 84; decrease in size of gland; general condition improved; gland presents characteristic diminution.

Dr. Leszynsky asked what was the change in the size of the gland generally.

Dr. Polon said from one to one and a half inches in the circumference of the neck on the level of the plane passing through the spine of the 7th cervical vertebra posteriorly and the most prominent point of the thyroid gland anteriorly.

Dr. Kennedy asked if the first patient had an oophorectomy as well as a hysterectomy.

Dr. Polon said no. He added a word of warning regarding the need of allowing a sufficient time to elapse (from 5 to 6 weeks) after the last *x*-ray before exposing the patient to the risk of operation, as the surgeon might find that the incision would not heal because of a radio-dermatitis which delayed its manifestation.

Dr. S. E. Jelliffe said he felt very much interested in the remarks of Dr. Polon. He wondered why the factor of etiology had been neglected. Exophthalmic goiter was due to a number of conditions, which were well known. The discussion should be limited to forms in which definite changes in the gland itself caused the condition. The changes supposedly due to emotional disturbance would not be helped by the *X*-ray. Unless there were glandular changes *per se*, patients were not likely to be benefited.

Dr KRAUS asked whether the blood changes had been followed in these cases. This might seem irrelevant, but, as Dr. Jelliffe had said, there were more than one kind of exophthalmic goiter; there was that caused by local thyroid changes and that caused by distant organs with functional thyroid changes; there were changes in the thymus, probably more frequently in the former group and depending upon the duration of the disease. The Germans had differentiated two types—Basedow-thyroid and Basedow-thymus. The former was associated with sympathetic symptoms in the main, the latter with parasympathetic, though this did not rule strictly. Basedow-thymus was often associated with a form of status thymolymphatis—the Kocher blood picture was said to be due to this status, hence it would be interesting to know the changes in the blood picture in order to appreciate whether any treatment were affecting the thymus and lymph system and in what way. Correlation of the symptoms in the light of the vegetative nerve system would help also.

Dr. TIMME said it would be interesting to know whether besides diminution in the size of the gland there was any relief of symptoms produced by enlarged thyroid. He had seen one case where the size of the thyroid was reduced by the parathyroid was stimulated to activity; the tremor and tachycardia were markedly increased. Following the cessation of *x*-ray treatment the patient was no better than before. In regard to the measurement of the decrease of the gland—it was a very difficult thing to get. He had seen an excellent method, devised by Dr. Woodberry, of Clifton Springs, for getting the upper and lower poles and the diameter of the thyroid gland.

Dr. ABRAHAMSON said the presentation of some of the cases treated by the method described was to call attention to this mode of therapy. This was merely a preliminary communication to encourage others to treat cases in a similar fashion. At a later date, when the number of cases reached 300, a more extensive study would be forthcoming. Then the various types of the disease and the many etiological factors would be grouped and studied. At present no such attempt had been made. At the present time there were certain types in which there was no improvement in signs and symptoms even though the thyroid had diminished markedly in size. They had had no accidents and up to date no myxedema. The role of suggestion as a cause for improvement was being considered carefully. Surgery had failed so often and here was a therapy apparently free of danger which yielded apparently good results. The future must decide.

Dr. ONUF said he would like to ask Dr. Polon how he would guard against bringing about myxedema, since to his knowledge the effect of the treatment often did not cease or did not become manifest until many months had passed after treatment had ceased, making it very difficult to let the reduction go to a certain desired point, and no further.

Dr. LESZYNSKY said he noticed no reference to exophthalmos and would like to ask if exophthalmos had existed and had disappeared.

Dr. POLON, in reply, said that with regard to the etiology of these cases they were able to establish in all, or almost all, an emotional factor. Nevertheless, they concluded that the emotional experience played a minor part in the etiology. It was often the last straw which broke the camel's back. The main interest and attention were directed to the clinical course of the disease, as it was affected by the decrease in the size of the gland through the agency of the *x*-rays. With regard to blood findings he regretted that no blood examinations were made, but provisions for doing so in the future were in progress. Regarding the diminution in the size of the gland upon the general symptoms they had come across three cases in whom, although a diminution in the size of the gland was affected, the symptoms still persisted. None of the cases shown to-night belonged to that group. In these there was a distinct ratio between the changes in the gland and the changes in the symptomatology. In regard to a more exact method of measuring the size of the thyroid gland they had found the spine of the 7th cervical vertebra and the most prominent point of the gland to be reliable, but would be glad to try the method spoken of by Dr. Timme. As to myxedema, they had met with no such experience. Speaking of exophthalmos, there was always exophthalmos of varying degree, but a pronounced exophthalmos appeared to be an unfavorable prognostic sign even if the ray caused shrinkage of the gland.

Address of Retiring President.—Dr. S. E. JELLIFFE said: "The Neurological Society was founded in 1872. After two years of stormy existence it was reorganized, and now represents the oldest society of its kind in the United States. It has a creditable history of 42 years of active service, and I feel it a special mark of privilege to have been chosen as your president, and to have served two years. What measure of success has been attained has been due to you, the individual members. I have tried solely to direct your energies and to make a platform upon which you could range your work with that of your precedessors. And now, in relinquishing the leadership, I wish to tender to you my word of thanks with sincere appreciation for the support you have accorded me. Retiring presidents seem to have left but few traces of their farewell utterances, for I am unable to find any guides which might be a lamp unto my feet in this most difficult of all tasks, namely, that of uttering one's own funeral oration. Turning to Holy Writ, therefore, for inspiration, I find that prophets have accrued much merit by foretelling what has already happened, and so in reviewing the work of the past two years I shall tell you what I had in mind, what I *had* planned to do, when you elected me president. Had you not meted out such good measure, heaped and running over, I would not have been such a good prophet. In view of this wealth of material, therefore, I shall not attempt any detailed recounting of it—most of you have contributed to it—I shall endeavor to give a somewhat rapid glance at the main trends: In the first place, the most striking feature of the material offered has been its great catholicity. All aspects of nervous structure and of functioning have received their attention, and a firm and progressive advance has characterized your activities.

"It has seemed feasible to regard the nervous system, speaking very broadly, as operating at three levels: through the course of ages these have been built up, not at all sharply delimited, but gradually and imperceptibly merging the one into the other, until this completed structure, through successive intergradations, has reached the dignity of the most important structure in the universe. These levels are familiar to you; we shall speak of them as the vegetative, the sensori-motor, and the psychical levels, respectively, and will utilize the terms, vegetative neurology, sensorimotor neurology, and psychical neurology, not as indicating three different kinds of neurology, but rather one, which working at different functional levels is finally integrated in that master spirit of evolution, the nervous system. Through countless ages that inexorable experimenter, Nature, has built up a series of successful models into a unity, the chief cleavages of which are merely suggested in order that such a conception might make the facts more readily handled. To attempt to make any such scheme of cleavage a ground for exclusion of any one level, as sufficient to handle the facts of neurology is to invite failure. Man is not solely a metabolic apparatus, accurately adjusted to an adaptive regulation of most marvelous efficiency and intricacy, through the vegetative neurological mechanism; nor do his sensoriemotor functions make him solely a feeling, moving animal, seeking that which we call pleasure and avoiding pain, conquering time and space by the enlargement of his sensory possibilities and by the magnification of his motor powers; nor yet is he solely a psychical machine, which by means of a masterly symbolic handling of the vast horde of realities about him has given him almost the power of reality itself. He is all three, and a neurology today that fails to interpret nervous disturbance in terms of all three of these levels fails in its high mission. This society has lived up to this criterion throughout its history and it has been the pride of each president that it has continued to carry out such a program.

"During the last two years you have presented, as contributions to the physicochemical level, much timely work, both new and important on the vegetative nervous system. The foundations laid by Langly and the English school have been built largely upon by the Vienna school, and all medical problems have had a new light thrown upon them by the more precise anatomical and physiological knowledge recently acquired in this field. Through the study of the reciprocal activities of the sympathetic and para-sympathetic systems, the entire group of metabolic activities has become much more comprehensible. The active and delicate adjustments of the physical and chemical needs of the tissues are, as we have seen, dependent upon these structures. Tissue hyperplasias, such as are seen in dermatosis, cirrhoses, scleroses carcinoses, gummatoses, etc., are the more readily explicable by means of this concept of the reciprocal activ-

ities of the vegetative nervous systems. The eminently practical problem of that which Eppinger and Hess have called the vagotonic constitution has been brought to your attention, and as a corollary flowing from these researches some of the most striking syntheses have resulted. Thus the activities of the whole group of the endocrinous gland disturbances has become comprehensible, and it is quite doubtful if a purely chemical concept, such as the hormone hypothesis will handle the facts. The anatomical pathways, the synaptic integrations, with the other levels, show readily why pain at a sensorimotor level may induce loss of tissue-tone and furthermore enable one to trace the anatomical and physiological connection between repressed desires, acting at the symbolic or psychical level, and enteroptoses, gastroptoses, vascular spasms and inequalities, skin atrophies and hypertrophies, and a host of changes in the body structures, a number of which have been shown here. A new syndrome, pilous adiposity, was presented before this society—an endocrinous constitutional anomaly. An entire revision of the whole embryology and anatomy of the hypophysis was a contribution from one of this society. The eminently practical problem of brain surgery, and some of the causes for disappointment following operations, was presented in which the kernel of the whole situation, namely, localized cerebral swelling, or tissue edema, receive its chief illumination from the study of the vegetative system activities upon the cerebral vessels.

"Thus not only every field of medicine, but many problems in surgery, receive most important clarification of the activities if the vegetative nervous system be taken into the mental grasp of the observer. Reluctantly I pass over this oldest phylogenetic level to even more hastily glance at the summaries and new work at the vital level which this society has fostered during the past two years. Perhaps the most striking of all the work in the field of sensorimotor neurology has been that clustered about the problems of syphilis of the nervous system. Early in 1913 the *Treponema pallidum* was discovered in the central nervous system, and demonstrated by its co-discoverer, one of your body. This discovery has settled the controversy relative to a host of problems upon nervous syphilis. In rapid succession we have had presented before us the attempts made to reach the organism by specific therapy in the elaboration of the Swift-Ellis treatment and its modifications; a thorough résumé of the pathological features involved has been presented, the peculiar lympathic blockings demonstrated, which throws some light on the difficulties of cerebral tissue penetration, and a group of experiments shown looking forward to the best means of seeking tissue penetration by remedial agents in order to reach the syphilis organism. This eminently practical problem of the treatment of all forms of nervous syphilis, suddenly reilluminated by the discovery of the causative factor, has also been clarified by a very full setting forth of contemporary experience from the chief clinics of Frankfort and Hamburg. This society has reason to congratulate itself that one of its members was the chief discoverer of the *Treponema pallidum* in the brains of paretics. Of the newer syndromes in sensorimotor neurology, which have been shown before us, may be mentioned, dystonia, musculorum progressiva, myotonia atrophica cauda equina neuritis, and progressive lenticular degeneration. Most illuminating and progressive work in spinal cord tumors has been brought to our notice and a large mase of fascinating clinical material of spinal cord and brain lesions, which I shall not burden you in relating. Cerebellar mechanisms and cerebellar localization have also claimed attention. Barany's important researches in localization and clinical cerebellar diagnosis have received extended discussion, while the cognate subjects of midbrain tremors, the pathology of the motor phenomena of paralysis agitans seen as lesions of the cerebellar static equilibrium pathways, the demonstrations of the extra pyramidal tract signs in disordered cerebellar disturbances in chorea, and the cerebellar types of multiple sclerosis and their separation from related lenticular degeneration syndromes, these have all come before us.

"Last, but not least, this society has not neglected the consideration of the most highly evolved and socially most valuable of all of the levels of the nervous system, *i.e.* the psychicial or symbolic. This is the most active field in neurology today, and its relationshin to the preceding phylogenetically older levels are being analyzed with bewildering activity. In no branch of medical science has the evolution of the concepts necessary to handle the facts been more active than in this particular field of psychical neurology. How rapid has been the change in formulations in the paranoia domain alone was the subject of my inaugural address. An entirely new light has been cast upon the subject of the traumatic neuroses and the unconscious factors of revenge have been laid bare. The psychogenic factors in a group of disorders, heretofore too narrowly viewed in the light of sensorimotor level affections, due to vegetative level disorders, has most amply shown that the psychical levels must not only not be ignored, but are probably the most important, if not the determining factors in the initial causation of these disturbances. It has already been shown how emotional *i.e.* psychic factors produce marked reactions at vegetative levels, that such reactions are capable even under experimental control of inducing transitory and permanent tissue changes, as has been demonstrated, following ligature applied to the vagus, for the changes in the gastric mucosa. Thus we have had presented the importance of psychical factors in epilepsy, in a group of tics, in tabes dorsalis, in spasmodic torticollis, in dementia præcox. Medicine is only on the threshold of this important field, in which an entirely new psychological scale, the Œdipus complex has been applied to measure all social phenomena. This concept, which in general means the instinctive biological direction of the reproductive instinct toward the parent of the opposite sex, and away from the parent of the same sex and its subsequent deviation or sublimation toward the socially permitted object in the ideal love relation, and the development of the Christian ideal of brotherly love, with the building up of the social group on the basis of the freeing of the individual frem the family neurotic romance, have been set forth in at least three different aspects. The interesting and important subject of comparative psychiatry has received illumination from a study of hysteria in a primitive folk, the Eskimo, while the problem of psychoses among the Jews has been presented in a masterly manner. The manic depressive psychoses among children have also received attention. The pragmatic aspect of the whole psychoanalytic movement has been set forth by means of a comparison with certain factors in modern philosophy, as seen in the work of Bergson, the factor that makes cures possible not only in psychoanalysis, but in the entire domain of psychical neurology, which makes up at a minimum 50 per cent. of the entire practice of medicine, has received attention in a study on transference, while the ethical implications and socially constructive values of psychoanalysis have been amply set forth at our last meeting. With such a record I feel we can pass on to even greater achievements in the year to come."

Address of the President-Elect.—Dr. W. M. LESZYNSKY said: "In assuming the office of President, I wish to express my thanks and also my appreciation of the honor conferred upon me. While it has been customary for the President-elect to deliver a so-called inaugural address or read a paper upon some neurological topic, I trust you will pardon me if I establish a precedent by dispensing with this time-honored tradition. Having no new policy to announce, nor new scheme to outline, you will not be disappointed, I am sure, when I tell you that I shall limit myself to a few brief remarks.

"Several years ago a former President-elect said in his address that the transactions of the meetings of the Neurological Society seemed to lack the animation and enthusiasm of former days, and he ascribed this to a phase of evolution, for want of a better explanation. There had never been any acrimonious discussion and harmony had always prevailed, but such a condition of affairs at that time, while apparently true, proved to be evanescent. Since then, neurology has become such a fascinating branch of medicine that it has attracted a larger proportion of practitioners and research workers than heretofore, the number of members in this Society being greater than has ever been known in its history. At the present time, however, a pessimistic attitude is not justifiable, for there are many fertile neurological fields awaiting development, which have not failed to interest an ever-increasing number of zealous and industrious students. On the other hand, we are still awaiting a satisfactory solution of the old but vitally important problem relating to the establishment and endowment of a special institution for the care and treatment of people of limited or moderate financial resources who are afflicted with disorders of the nervous system. The lack of suitable and adequate provision for a large and rapidly increasing number of such unfortunates, who are ineligible for admission to a general hospital, or institution for the insane, is more in evi-

dence than ever. While this subject does not come strictly within the scope of our scientific deliberations, it is of such paramount importance at the present time that I would suggest that you, at least, present this aspect of medicosocial economics to the attention of all philanthropically inclined persons on all befitting occasions.

"It would seem that this is an opportune time for a passing reference to the subject of psychoanalysis and it is not without some hesitation and personal misgiving that I touch upon this topic. It must have been evident to any unprejudiced observer that more time has been devoted to discussion (both polemical and uncomplimentary) in this field of endeavor, than is commensurate with the results, when we consider the antagonism it has engendered, and that its applicability is admittedly restricted. In consequence of the energy expended by its advocates and opponents, particularly the former, a new era seems to have dawned upon us recently, in which neurology has become threatened with a subdivision into specialties, namely, organic neurology and esoteric Freudism. Whether or not this is a significant sign of parlous times, it is impossible to state, but I am, however, unwilling to admit, that the majority of neurologists are sufficiently credulous to seriously entertain such a chimerical notion. Without entering into a discussion upon the merits of such a revolutionary tendency, permit me to state that the New York Neurological Society will, nevertheless, continue to welcome the unorthodox agitators among its members, although the present administration has pledged itself to maintain its well-established scientific and ethical standards.

"Among the younger members of the Society are many possessed of neurological training of a high order, to say nothing of ambition and enthusiasm, and who have been frequent and valued contributors at our meetings. There are others who undoubtedly possess similar qualifications and much latent talent, but have remained inactive probably through diffidence. Let us hope that this Society will never suffer from a superabundance of latency, an unfortunate condition which has so often proven fatal to progress in other organizations. It will always be our endeavor to encourage the younger men to actively participate in our scientific work. The presentation of clinical material demonstrating uncommon or rare types of disease of the nervous system will continue to be one of the essential features of our program.

"In conclusion, let me urge upon you, regular and prompt attendance at our meetings and bespeak your active support and co-operation, trusting that during the present year, a new impetus will be given to neurological research, through the energetic efforts of the members of this society."

An Analysis of the Action of Morphine in the Light of the Vegetative Nervous System.—Dr. WALTER MAX KRAUS presented this paper. He stated that the action of morphine in terms of the old pharmacological conception was said to be narcotic. However, the action upon the eye and the bladder sphincters was accelerating. Thus the narcotic effect did not extend to all parts. Considered in the light of the new pharmacological conceptions of the vegetative nervous system, we found that morphine increased the activity of the vagus to the heart, and decreased the activity of the vagus to the gastrointestinal tract. Thus it was not universally depressant. It should not be forgotten that small doses of a drug might have an opposite effect to large doses. This applied to morphine. Morphine in therapeutic dosage depressed all secretions except that of sweat, and depressed this in chronic morphinism. All smooth muscles were depressed in activity except the sphincters of the eye and bladder. But morphine acted upon the central apparatus, not the periphery. By analogy to natural or chloral hydrate sleep, we could see that myosis was depression. Thus, morphine's action equalled functional depression. The two functions of the bladder, to hold and to excrete urine, were depressed. If it were full, and unemptied, due to sphincter spasm, it could hold no more—diminished function; and if there were sphincter spasm it could not excrete—diminished function. Morphine did not increase the motor reflex activity of the spinal cord in therapeutic doses. Hence it stimulated, if anything, cerebral inhibition instead of narcotizing it. The example of stimulation of inhibition (heart vagus) and depression of stimulation (intestinal vagus), was true of all other vegetative organs. Dr. Kraus concluded, therefore, that the central effect of morphine in moderate dosage was to increase inhibitory actions and to decrease stimulatory actions. The peripheral result was always depression of function.

Dr. S. E. JELLIFFE said that he could not add anything to this paper. He would like to ask Dr. Kraus if he had any light to throw upon the action of drugs on the synaptic junction. What effect would there be, for instance, of nicotine on the one hand and strychnine on the other?

Dr. W. D. TIMME said that Dr. Kraus had made good use of his facts. It was very difficult to generalize on this subject. What generalization was possible he had used. To suggest some of the difficulties of such an investigation—in the first place morphine was always said to have a depressing effect upon the sympathetic centers and a corresponding irritating effect upon the autonomic or parasympathetic centers. That was only true in man and one or two animals, for instance, dogs. In cats the effect was quite the contrary. In cats we had a peculiar action of the pupil; it dilated; so also was the case in the bovine. So there we had a contradictory action of morphine. There were differences in the anatomic and the physiological autonomic systems, from the pharmacological autonomic system. Langley, Bayliss and Starling had traced the physiological sympathetic influence of the control of the sweat glands in the skin. Meyer, of Vienna, had proved that these glands were affected by an autonomic stimulus, such as pilocarpine. When it was seen that the influence was different in man from the lower animals, and that even in man it did not correspond to the anatomical conditions, to correlate these facts with such a drug as morphine was very difficult. Dr. Timme said he understood that this was a preliminary paper. If the investigation was to continue and be subjected to the proper controls, he thought the work was highly necessary, not only with morphine, but with other drugs.

Dr. KRAUS said that as he understood Dr. Jelliffe's question, he asked upon what point in the course of the nerve fiber morphine acted. Nobody knew definitely, as far as he could say. If one took two lines representing sympathetic and parasympathetic fibers and joined them by a third, centrally, one had the general plan. The action was not peripheral. Hence it must be central. It was in all probability upon connections between the sympathetic inhibitory center and the parasympathetic center. This inhibitory mechanism must be much like that described by Sherrington for the regulation of agonist and antagonist.

Dr. JELLIFFE said he did not know about the center. His question was in regard to neurones. The periphery received the stimulation and passed it on to the next neurone, over the synaptic junction.

Dr. KRAUS added that the action of morphine was stimulatory upon some centers, depressant upon others. It was confusing at first. It was impossible to account for the action, if it was called depressant, upon the center. It could not be so upon the intestine for instance, for if it depressed the central sympathetic inhibition to the parasympathetic centers, the vagus would be overactive, which it was not. As to the sweat glands this was the one exception to the rules of vegetative neurology. Though the sympathetic nerves upon electrical stimulation caused sweating, adrenalin did not and pilocarpine did. In chronic morphinism there was hypoidresis. The action of morphine in many other animals was very complex, but in man he felt certain that it was as he had represented.

The Origin of the Blood Platelets. — Carlo Martelli states that these bodies are not a third independent element of the blood. Some of them result from a breaking up of white blood cells, while others are the product of the involution of red blood cells—*Pathologica.*

Hexamethylenamine in the Cerebrospinal Fluid.—W. Usener states that in serous meningitis and hydrocephalus the amount of this drug that is excited in the cerebrospinal fluid is the same as under normal conditions. In tuberculous meningitis, however, there is a distinct diminution in the amount of this excretion.—*Zeitschrift für Kinderheilkunde.*

Sea Climate and the Morphology of the Blood. — E. Conradi notes that apart from a slight increase in the number of erythrocytes and the amount of hemoglobin there are no morphological changes in the cellular elements of the blood under the influence of sea climate.—*Folia Hæmatologia.*

INDEX.

A

Abbe, R., uterine fibroids, menorrhagia, and radium, 379.

Abderhalden reaction, 324, 525, 1037; after transplantation of organs, 79; clinical value, 241; in veterinary practice, 945.

Abdomen, after-treatment in operations on, 695; and thorax, acute diseases of, 789; disease of, and superior mesenteric vessels, 797; gunshot wounds of, 158; inflammatory tumors of, 817; leucocytosis in hemorrhages of, 742; septic condition in, 996; symptoms of, in pleurisy and pneumonia, 577.

Abortion, criminal, 405; legalized, 816.

Abrahams, R., indications for treatment of heart diseases, 683.

Abscess, subpectoral, 658.

Accidents and alcohol, 952.

Accident insurance, 829; and death caused partly by accident, 327; and medical profession, 537; medical aspects of, 34.

Acid crises, 897.

Acidosis, and surgery, 793; in children, 952.

Acids and alkalies in organic world, 524.

Aconite, renaissance of, 231.

Acromion, concretions below, 792.

Addison's disease, case of, 207.

Adenitis, tuberculous, cervical, 155; tuberculous cervical and tonsils, 155.

Adiposity, pilous cerebral, 249.

Advertisements, medical, right to publicity, 442.

Aeschylus, a doctor's study, 341.

Air, impure, dangers of, 564.

Alcohol, and accidents, 952; and the circulation, 533; criminality caused by, in Bavaria, 495; campaign against, in Munich, 863; in army, 365; in war, 33.

Alcoholism, and life expectancy, 201; and the intoxication impulse, 253; subacute, treatment of, 252.

Alexia, 1081.

Alimentary canal, intoxication from, in infants, artificial serum injections in, 924.

Alkalies and acids in organic world, 524.

Alkaloids, and fullers' earth as an antidote, 998.

Allylmorphine, 882.

Alopecias, the, 852.

Alzheimer's disease, 335.

Amebiasis, intestinal, 578; urinary, 955.

American Medical Association: Addresses of welcome by the medical profession, to California, and to San Francisco, 1087; election of officers and place of next meeting, 1093; president's address, 1084, 1087; report of Board of Trustees, 1084; report of committee on anesthesia, 1086; report of committee on cancer, 1086; report of committee on conservation of vision, 1086; report of committee on co-operation with the National Educational Association, 1086; report of committee on expert testimony, 1086; report of committee on nomenclature and classification of diseases, 1086; report of committee on section work, 1087; report of committee on scientific research, 1086; report of committee on uniform regulation of membership, 1086; report of council on medical association, 1086; report of council on public health and public instruction, 1085; report of judicial council, 1084; report of Red Cross committee, 1086; report of committee on welfare of women and children, 1086.

Ames, T. H., psychogenic convulsions, the result of a wish, 899.

Amino-acids in blood and spinal fluid, 156.

Amputation, and asepsis in war, 326; in war, 157.

Analgesia, novocain-suprarenin, in repair of inguinal hernia, 896.

Anaphylaxis to fly stings, 495.

Anemia, and cholesterinemia, 70; pernicious, 207; pernicious, splenectomy in, 230, 493, 570; pernicious, treated by transfusion, 163; pernicious, treated with cholesterin, 1077; pernicious, treated with salvarsan, 579; severe, with leg ulcer, 1004; splenic, 532; splenomegalic, treated by transfusion, 331.

Anesthesia, gas-oxygen-ether, apparatus for, 980; local, cesarean section under, 288; local, in general surgery, 289; local, in repair of inguinal hernia, 896; local, in thyroid surgery, 289; nitrous-oxide, in obstetrics, 494; nitrous-oxide-oxygen, fatal asphyxia under, 282; parametrian conduction, 285; sacral, 288; scopolamine-morphine, in abdominal surgery, 290; scopolamine-morphine, in obstetrics, 289; scopolamine - morphine - cocaine in surgery, 1078; scopolamine-narcophine, as used in Freiburg clinic, 289; scopolamine-narcophine, in labor, 599 (see also "twilight sleep"); spinal, in general surgery, 288; spinal, in gynecology, 492; spinal, in South America, 288.

Anesthetic, administration of, in intent to procure abortion, 569.

Aneurysm, arteriovenous, 914; arteriovenous, of the carotid, 921; ligation of first part of subclavian for, 331; of superior mesenteric artery, 1080; ruptured, of left vertebral artery, 543; war, 274.

Angina, pneumococcus and its treatment, 325; Vincent's, 58; Vincent's, local applications of neosalvarsan in, 840.

Ankylosis, 282.

Anosodiaphoria and anosognosia, 521.

Anosognosia and anosodiaphoria, 521.

Anthrax and war, 158.

Antivaccination in disguise, 231.

Antisepsis, and asepsis in war, 23; versus asepsis, 154.

Antiseptics, diffusibility and inhibitory qualities of, 1047.

Antisera, production of, 436.

Anuria, salvarsan, hypertonic solutions in, 997.

Anus, fistula in new operation for, 519; prolapse of, in children, 72.

Aorta, descending thoracic, dilatation of, 540.

Aortitis, syphilitic, 787.

Aphasia, and apraxia, 30; optic, 1081.

Appendicitis, 952; acute, and acute appendicular obstruction, 31; acute obstruction of, 704; and focal infection, 798; and sciatica, 364; cause of, 1038; clinical study of, 557; chronic, conditions simulating, 198; electric localization of streptococcus in, 959; from grazing bullet, 326 in soldiers, 955; in the army, 111; operation, catharsis after, 451; pseudo-, in a physician, 536; treated with anti-colon-bacillus serum and vaccine, 199; verminous, treatment of, 504.

Appendix, pigmented, 283, 362.

Apraxia and aphasia, 30.

Army, medical reserve corps of, 192; rum ration, 365; United States, report of surgeon-general of, 64.

Armies, allied, health of, 358.

Arsenic excretion in urine following use of salvarsan, 588.

Arteries, contour of normal pulse of, 788; coronary, action of opium alkaloids on, 825; heart, and kidneys, chronic diseases of, 925; syphilis of, 877; wounds of, 71.

Artery, middle meningeal, hemorrhage from, 120; superior mesenteric, acute aneurysm of, 1080.

Arteriosclerosis, 913, 1079; and ophthalmologist, 913; and uterine hemorrhage, 913; recent views on, 818.

Arthritis, deformans, ileocolostomy and colectomy for, 1093; elective localization of streptococci in, 959; gonorrheal, pituitary extract in, 1024; oral osteitis in relation to, 427; rheumatoid, 206; rheumatoid, and rheumatic fever, 1080.

Articulation, derangement of inferior radio-ulnar, 708.

Asepsis, and amputation in war, 326; and antisepsis in war, 23; versus antisepsis, 154; technique of, 787.

Aspinwall, F. E., the homograde thermometer, 856.

Association of American Physicians, president's address, 1003; report of George Washington memorial committee, 1003.

Associations, medical, and defense of their members, 650; advantages of, 631.

Astasia-abasia, in multiple neuritis, 70; recovery in, 673.

Asthma, bronchial, and life insurance, 410; bronchial, treatment of, 252; horse, horse-serum treatment of, 952.

Atrophy, progressive neuromuscular, 576; syphilitic muscular, 1096.

Auer, E. M., anosognosia and anosodiaphoria, 521.

Auricles, fibrillation of, 207, 505, 710.

"Auscultoplectrum," 282.

Autopsy, as public service, 870; plea for, 149.

Autoserotherapy in dermatology, 336; 703.

Aviator, darts of, injuries from, 524.

Aviation, hygiene of, 1006.

B

Bacillus, colon, effect of, on kidney, 240; in pasteurized milk, 741.

Bacteria, hemoglobinophilic, infections with, 997; of colon typhoid group, newer, 735.

Baker, V. C., neurasthenia among garment workers, 592.

Balantidiosis treated with emetine, 495.

Baldwin, J. F., splenectomy for pernicious anemia; apparent recovery; death, 250.
Ballard, L. W., the *x*-ray as an ideal local remedy for eczema, 523.
Ballenger, E. G., a new mission for variocele operation when the scrotum is to be amputated, 355.
Bandler, S. W., the use of pituitary extract in obstetric practice, with some critical observations on "twilight sleep," 55.
Barber, W. H., chronic dilatation of the stomach; a clinical and experimental study, 718.
Barnes, F. H., medical inspection of schools in Connecticut, 20.
Barnich, S., simplifying hydrotherapy, 820; the giving of Mariaheim baths in this country, 972; the psychology of the tuberculous, 310.
Bechet, P. E., diseases of the skin in pregnancy, 19.
Beck, A. L., suggestion narcosis, 1069.
Bedsores, treatment of, 882.
Beebe, S. P., medical news in the *New York Times*, 403.
Bell, R., the natural history of cancer, 939.
Benedict, A. L., artificial gastric juice in gangrene, 655; speech elementary sounds, 506.
Benzol, and its homologues, action of, 946; in leucemia and lymphosarcoma, 579.
Beriberi and white bread, 151.
Bile, ducts, cancer of terminal portion of, 149; feeding of, in biliary obstruction, 1037.
Binet-Simon tests in psychoses of senium, 493.
Bishop, L. F., some recent work in cardiovascular disease, 173.
Bissell, J. B., radium therapeutics, otherwise than for malignancy, 1023.
Bladder, bullet extracted from, 158; cancer of, 734; diverticulum of, 450, 531; excision of, for cancer, 71; hypertrophied, 588; papilloma of, 1037; quinine bisulphate in irrigation of, 323; total ectopia of, 663; ulcer in women, rare type of, 868.
Blakely, S. B., the medicine of the Old Testament, 934.
Blindness, color, and color vision, 112; from facial eczema, 542; snow, in troops, 325; Soul, 1081.
Blodgett, S. H., prophylaxis of puerperal convulsions, 478.
Blood, amino-acids in, 156; coagulation in infancy, 831; ferment of, 995; incoagulability of, in hemoptysis, 191; physicochemical studies on, 104; serum, decanted, in the treatment of hemorrhage and hemophilia, 647; transfusion of, see transfusion; uric acid of, 905; vessels, large, shot wounds of, 242; vessels, suture of, in war surgery, 199.
Blood pressure, and altitude, 997; clinical significance of, 473; during pregnancy, 282; estimation in children, 789; high, and thyroid intoxication, 1067; study of, and its value in clinical medicine, 1062; variations and their treatment, 269.
Blum, H., a few suggestions on handling cases of diabetes mellitus, 687.
Blumenthal, S. J., a new operation for fistula in ano, 519.
Boil, Oriental, 955.
Bone, callus, 696; cancellous, lesions of, 333; graft in surgery, 669; regeneration, 778; secondary carcinoma of, 1037; surgery, misapplied, 669, 740.
Book Reviews:
Abdominal operations, Vols. I and II, by Sir B. Moynihan, 830.
Air, water, and food from a sanitary standpoint, by A. G. Woodman, 411.
Alcohol, the question of, by E. H. Williams, 1043.
Anatomy, human, Morris's, edited by C. M. Jackson, 623.
Anatomy of the domestic animals, by S. Sisson, 1083.
Anatomy of the human skeleton, the, by J. E. Frazer, 664.
Anatomy, practical, Cunningham's manual of, revised and edited by A. Robinson, 369.
Anatomy, Quain's elements of, edited by Sir E. A. Schäfer, J. Symington, and T. H. Bryce; Vol. II, part 2, splanchnology, by J. Symington, 497.
Anesthesia, local and regional, by C. W. Allen, with an introduction by R. Matas, 623.
Anesthesia, local, by A. Schlesinger; translated by F. S. Arnold, 35.
Anesthesia, local, by H. Braun; translated and edited by P. Shields, 368.
Anoci-association, by G. W. Crile and W. E. Lower; edited by A. F. Rowland, 369.
Appendicitis, a plea for immediate operation, by E. Owen, 328.
Arzneimittel, die neueren, von H. Skutetzky und E. Starkenstein, 497.
Augenpflege, von Dr. Elsching, 917.
Augenverletzungen im Kriege und ihre Behandlung, von C. Adam, 875.
Augen, über die Ernährung des, von C. Hamburger, 35.
Auricular flutter, by W. T. Ritchie, 244.
Backward baby, the, by H. B. Sheffield, 875.
Bacteriology, clinical and applied, a manual of, by R. T. Hewlett, 706.
Bacteriology, general, by E. O. Jordan, 368.
Bäderbuch, Oesterreichisches, von K. Diem, 116.
Bakteriologische Untersuchungen des Ixemgenates im Genitalkanale der Gebärenden Wöchnerinnen, von Dr. Mund, 202.
Bones and joints, diseases of, by L. W. Ely, 202.
Cancer, its cause and treatment, by L. D. Bulkley, 706.
Cancer problem, the, by W. S. Bainbridge, 411.
Cancer, the problem of, or the philosophy of malignancy, by E. C. Savidge, 1083.
Carcinoma of the thyroid in the salmonoid fishes, by H. R. Gaylord and M. C. Marsh, 411.
Child training as an exact science, by W. W. Jacoby, 706.
Chirurgie de guerre, par E. Delorme, 161.
Circulation, therapeutics of the, by Sir Lauder Brunton, 706.
Clinics, international, edited by H. W. Cattell, Vol. IV, twenty-fourth series, 1914; 917; Vol. I, twenty-fifth series, 1915, 1083.
Clinics of John B. Murphy, M.D., Vol. III, No. 4, 287; Vol. III, No. 5, Vol. III, No. 6, 1002.
Cornell University Medical Bulletin, Vol. IV, No. 2, October, 1914; studies from the department of neurology, 917.
Defective children, edited by T. N. Kelynack, 958.
Dental anatomy and physiology, aids to, by A. S. Underwood, 664.
Dental anatomy, human and comparative, a manual of, by C. S. Tomes; edited by C. S. Tomes, E. W. M. Tims, A. Hopewell-Smith, and J. T. Eriseman, 456.
Dental surgery, edited by M. G. Bennett, with an appendix on dental jurisprudence, by P. B. Henderson, 116.
Diagnosis, clinical, by J. C. Todd, 1083.
Diagnostic and therapeutic technique, by A. S. Morrow, 1002.
Dictionary, a practical medical, by T. L. Stedman, 161.
Dietetics, by W. Tibbles, 368.
Diseases, the commoner, their causes and effects, by L. Jores, translated by W. H. Woglom, 875.
Dissection methods and guides, by D. G. Metheny, 1043.
Doctor's viewpoint, by J. B. Huber, 76.
Experimentation, animal and medical progress, by W. W. Keen; with an introduction by C. W. Eliot, 917.
Fear and conventionality, by E. C. Parsons, 830.
Feces of children and adults, by P. J. Cammidge, 76.
Fever, by I. Ott, 830.
Formulary, pocket, for the treatment of disease in children, by L. Freyberger, 456.
Frauenheilkunde, kurzgefasstes Handbuch der gesamten, edited by W. Liepmann, Ed. II. Pathologische Anatomie und Histologie der weiblichen genitalorgane, by O. Frankl, 202.
General paralysis, focal symptoms in, by C. M. Campbell, 1043.
Germ-cell cycles in animals, the, by R. W. Hegner, 244.
Glaucoma, edited by W. O. Nance and W. H. Peck, 958.
Glaucoma, sclerocorneal trephining in, by R. H. Elliot, 35.
Gonorrhœa and its complications in the male and female, by D. Watson, 1002.
Heart, the balneo-gymnastic treatment of chronic diseases of the, by L. Schott, with a foreward by J. M. Anders, 328.
Heart, the, in early life, by G. A. Sutherland, 411.
Ileocecal valve, the, by H. H. Rutherford, 328.
Immunitätsforschung, experimentellen Therapie, Bakteriologie, und Hygiene, herausgegeben von W. Weichardt, 496.
Infection and resistance, by H. Zinsser, with a chapter on colloids and colloidal reactions by S. W. Young, 287.
Infektionskrankheiten, Lehrbuch der von G. Jochmann, 1083.
Jurisprudence, medical, by E. D. Brothers, 368.
Karzinome, die Entstehung und Behandlung der, von H. Theilhaber, 244.
Laboratory work, public health, by H. R. Kenwood, 538.
Labyrinth, diseases of, by E. Ruttin, with a foreword by V. Urbantschitsch; translated by H. Newhart, 35.
Laryngological Association, American, transactions of, thirty-sixth annual meeting of, 664.
Massage, Lehrbuch der, von A. Müller, 497.
Massage and remedial gymnastics, by L. L. Despard, 830.
Medicine, modern, edited by Sir William Osler and T. McCrae, Vol. III, 76; Vol. IV, 538.
Medicine, progressive, edited by H. A. Hare, assisted by L. F. Appleman, 664, 1083.
Microorganisms, pathogenic, by W. H. Park and Anna W. Williams, 456.
Midwives, a textbook for, by J. S. Fairbairn, 456.
Military hygiene and sanitation, by F. R. Keefer, 35.
Nervous and mental diseases, by A. Church and F. Peterson, 1043.
Neurological Institute of New York, contributions from the third division of, 1043.
Nose and throat, diseases of the, by J. Wright and H. Smith, 76.
Nose, throat, and ear, diseases of, by E. B. Gleason, 161.
Nose, throat, and ear, operative surgery of the, by H. W. Loeb, Vol. I, 623.
Nursing manual for nurses and nursing orderlies, by D. C. L. Fitzwilliams, 917.
Obstetrics, case histories in, by R. L. De Normandie, 456.
Obstetrics, manual of, by E. P. Davis, 328.
Œdema and nephritis, by M. H. Fischer, 538.
Oesophagoskopie, von H. Starck, 161.
Ophthalmie, die sympathische, von A. Jess, 917.
Optic projections, by S. H. Gage and H. P. Gage, 875.
Orthopædics indispensable to practitioners, by F. Calot; translated by H. H. Robinson and L. Nicoll, 623.
Pathological technique, by F. B. Mallory and J. H. Wright, 1043.
Pathology, a textbook of, by F. Delafield and T. M. Prudden; revised with the cooperation of F. C. Wood, 287.
Pathology, textbook of, by J. G. Adami and J. McCrae, 35.
Pellagra, transactions of the National Association for the Study of, second triennial meeting, 1912, 197.
Pharmacology, handbook of, by C. W. Greene, 116.
Pharmakologie, die experimentelle, von H. H. Meyer und G. Gottlieb, 1002.
Physiology and practical exercises, a manual of, by G. N. Stewart, 369.
Physiology, essentials of, by F. A. Bainbridge, 244.
Physiology, Kirke's handbook of, revised and rewritten by C. W. Greene, 35.
Physiology, pathfinders of, by J. H. Dempster, 456.
Poisons and powerful drugs, laboratory manual for the detection of, by W. Autenrieth; translated by W. H. Warren, 623.
Problem of the nations, a study of sexual disease, by A. Corbett Smith, 116.
Psychiatrischen Diagnostik, Grundriss der, von J. Raecke, 958.
Psychopathic Hospital, Boston, contributions from, 958.
Public health administration, legal principles of, by H. B. Hemenway, with an introduction by J. H. Wigmore, 1042.
Race betterment, proceedings of the first national conference on, edited by the secretary, 664.
Rectum and anus, diseases of, by P. Lockhart Mummery, 664.
Röntgen-Therapie, von H. E. Schmidt, 917.
Röntgendiagnostik in der inneren Medizin, Grundriss und Atlas der, von F. M. Groedel, 664.

Saber and scalpel, with the autobiography of a soldier and surgeon, by J. H. Wyeth, 369.
Salvarsan treatment of syphilis in private practice, by G. Stopford-Taylor and R. W. Mackenna, 875.
Shortt, Thomas (principal medical officer in St. Helena), with biographies of some other medical men associated with the case of Napoleon from 1815 to 1821, by A. Chaplin, 1043.
Sick-room, the care of the, by E. G. Cutler, 1043.
Skin, diseases of, by F. C. Knowles, 244.
Smith, Nathan, life and letters of, by E. A. Smith, with an introduction by W. H. Welch, 116.
Surgical practice, guiding principles in, by F. E. Neef, 202.
Surgery, operative; head and neck, the thorax, and the abdomen, by E. H. Taylor, 161.
Surgery, Rose and Carless' manual of, revised by A. Carless, 328.
Surgery, urgent, by F. Lejars, translated by W. S. Dickie; Vol. I, introductory head, neck, chest, spine, abdomen, 875.
Surgical operations, textbook of, by F. Krause, in association with E. Heymann; translated and edited by A. Ehrenfried, 1042.
Syphilis and locomotor ataxia, the intensive treatment of, by Aachen methods, by R. Hayes, 958.
Therapie, Taschenbuch der, von M. T. Schnirer, 458.
Tonsils, the faucial, lingual, and pharyngeal, by H. A. Barnes, 497.
Tropical diseases, by Sir P. Manson, 497.
Tropical diseases, diagnostics and treatment of, by E. R. Stitt, 917.
Tuberculosis, acute general miliary, by G. Cornet, 368.
Tuberculosis, atmospheric air in relation to, by G. Hinsdale, 116.
Tuberkulose, Lehrbuch der spezifischen Diagnostik und Therapie der, von Drs. Bandelier und Roepke, 1042.
Untersuchungsmethoden, klinischen, chemisch-mikroskopischen und bakteriologischen, von M. Klopstock und A. Kowarsky, 830.
Vaccination question, by C. K. Millard, 116.
Venenpuls und Herzschallenregistierung, von R. Ohm, 244.
Vision, color, an introduction to the study of, by J. H. Parsons, 1083.
Weight reducing comfortably, by G. Gaertner, 411.
Worry and nervousness or the science of self-mastery, by W. S. Sadler, 1002.
Boorstein, S. W., chronic progressive polyarthritis, or arthritis deformans, with a report of one hundred and five cases, 1009.
Borgmeyer, J. G. L., an appliance for producing simultaneous suction and pressure for use in tonsil and adenoid operations, 732.
Borneo, sanitary conditions in, 950.
Bottle, nursing, a new, 442.
Boudewyns and Marcquis, Drs., of Antwerp, 975.
Brain, and cord, traumatic separation of, 543; decompression of, 198; in psychopathic subjects, 281; lesion of, preservation and Jacksonian epilepsy in, 290; multiple sarcomata of, 963; physiology of, study of, during war, 872; sarcoma of meninges of, 730; tumor involving hypophysis secondarily, 290; tumor, operations for, 197; with double frontal abscesses, 412.
Brannan, J. W., observations on twilight sleep, 715.
Bread, color analysis of, 619; German army, 873; war, and digestive disorders, 871; properties of, 1040; white, and beriberi, 191.
Breast, cancer of, 792; gelatinous carcinoma of, diagnostic sign of, 914.
Brickner, W. M., a simple, easily regulable method of applying abduction in the treatment of shoulder disability, 15.
Brides, war, 816.
Bronchitis, chronic, and emphysema, treatment of, 546; in children, apomorphine in, 252; treated with menthol eucalyptol, 200.
Bulkley, L. D., medical aspects of cancer, 799.
Bumsted, C. V. R., some clinical features of exophthalmic goiter, 467.
Burke, C. B., thyroglossal cysts, report of a case, 1021.
Burnham, A. C., the rôle of the physician in industrial medical insurance, 854.
Burns, in infant, treatment of, 924.
Bursitis, subacromial, 121.

C.

Calcium, chloride and hemolysis, 241; chloride in tic convulsif, 73; chloride, therapeutic uses of, 638; salts, action of, 619; salts, insoluble, intramuscular injections of, 1008.
Calvé-Perthes' disease, 581.
Camphor, synthetic, 696.
Cancer, and advertised remedies, 117; deep seated, *x*-ray treatment of, 221, 825; destruction by radium, 754; in relation to fuel, 779; inoperable, a treatment for, 912; inoperable, treated with goat serum, 284; natural history of, 939; of breast, 792; of bladder, 754; of colon, 796; of skin, treatment of, 533; of stomach, 827, 848; of stomach in a boy of nine, 828; of stomach, diagnosis of, 1058; of stomach, early recognition of, 796; of terminal bile and pancreatic ducts, 149; medical aspects of, 793; organotherapy in, 961; plastic surgery in, 824; radium treatment of, 200, 454; skeletal, 786; *x*-ray treatment of, 145.
Carbon, iodized, in treatment of infected wounds, 613; monoxide poisoning, erythema due to, 420.
Carcinoma, in the young, 730; secondary, of bone, 1037.
Cardiovascular disease, 173; in warfare, 200.
Care and skill, degree required, 483.
Carnivorous and herbivorous types in man, 492.
Carotid, arteriodenous aneurysm of, 921.
Carter, W., two cases of depressed nasal deformity resultant from the submucous operation, 813.
Casts, diphtheritic tracheobronchial, 728.
Catarrh, infectious, complications of, 874.
Catatonia in manic-depressive insanity, 311.
Cerebellum, uterolith from, 1007.
Celluloid tube in finger injuries, 914.
Cereals in milk modification, 396.
Cerebellum, diplegia from disease of, 963; tumor of, 543.
Cerebrospinal fluid, 370, 659; absorption of, 23; amino-acids in, 156; gold-sol test in, 576, 824; in pneumonia, 703.
Certificate, false, use of, 859.
Cesarean section, extraperitoneal, 197.
Chemotherapy, of tuberculosis, 694; of tumors, 741.
Chest, shot wounds of, 1000.
Childbirth painless, 118; see also scopolamine-morphine and scopolamine-narcophine semi-narcosis, and "twilight sleep."
Children, atypical, 885.
Chinaman, health and physique of, 25.
Chloroform, poisoning, delayed, 72.
Cholangitis treated with tincture of boxwood, 966.
Cholecystitis, and focal infection, 797; electric localization of streptococci in, 959; treatment of, 1095.
Cholelithiasis, pleurisy associated with, 536.
Cholera, and war, 743; treatment of, 321.
Cholesterin, and giant-cell tumors of the tendons and joints, 534; therapy in pernicious anemia, 1077.
Cholesterinemia and anemia, 70.
Chorea, antipyrine in, 966.
Christian Scientists, insurance of, 874.
Ciliary body, 1038.
Circulation, and alcohol, 533; reversal of, 532.
Clark, L. P., further observations on the tic neurosis, 171; outlines of a State policy for dealing with mental deficiency, 665.
Clubfoot, double, in twins, 1022; treatment of, 794.

Kahn, A., an electrical mouth light, 609.
Kaliski, D. J., a cannula and needle for blood transfusion and intravenous infusions, 482.
Kanstoroom, D. S., the significance of acids and alkalies in the organic world, 524.
Kaolin, use of, for removing bacteria from throat and nose, 1079.
Keratosis follicularis spinulosa, 756.
Kidneys, and ureter, anomalies of, 164; atrophy of, from ureteral calculus, 77; decapsulation of, 156; decapsulation of, for unilateral hematuria, 790; effect of colon bacillus on, 240; fatty degeneration of, 77; heart, and arteries, chronic diseases of, 925; hematogenous infection of, 577; horseshoe, 165; infections of, 363; lesions, regeneraion following, 915; movable, operation for, 112.
King, E. H., intestinal paresis, its treatment by means of pituitary extract, 180.
Knapp, A., the prognostic significance of changes in the retinal vessels, 883.
Konkle, W. B., Aeschylus—a doctor's study, 341.

L

Labor, see parturition.
Labyrinthitis following operation for atresic, 912.
Lake, G. B., gonorrhea treated with sucrose-imide of mercury administered intramuscularly, 643.
Lambert, A., the intoxication impulse, 253.
Lamn, Nagelschmidt modification of Kromayer quartz, 773.
Landau, reaction of, 924, 1079.
Langhorst, H. P., the streptococcus peril, 184.
Larkey, C. J., an appliance for producing simultaneous suction and pressure for use in tonsil and adenoid applications, 732.
Laryngopharynx, lymphoid growths of, 264.
Larynx, abductor paralysis of, 168; diseases of, dry-cupping in, 283; obstruction of, 604; superior nerve of, alcohol injection of, 239; tuberculosis of, treatment of, 81; tuberculosis of, treatment of dysphagia of, 840.
Lawsuits, baseless, for injuries, 609.
Laxative powder, 630.
Lead, local action of, 1071; workers, effect of military training upon, 789.
Leg, ulcer, with severe anemia, 1004.
Lenticular degeneration, Wilson's, 250.
Leprosy, chaulmoogra oil in, 105; pulse and temperature in, 786; study of, 824.
Leszynsky, W. M., further observations on the treatment of sciatica by perineural infiltration with physiological saline solution, 211.
Leucemia, 994; acute lymphatic, 913; an infection, 1090; benzol in, 527; lymphatic, following splenectomy, 281; lymphatic, without lymphatic enlargement, 542.
Leucocytes, during digestion in infancy, 924; count of, differential, 336.
Leucocytosis in abdominal hemorrhage, 742.
Levinson, A., a case of diphtheritic tracheobronchial casts in a woman 50 years of age, 728.
Lewisohn, R., a new and greatly simplified method of blood transfusion, 141, 195; priority in the use of citrated blood for transfusion, 448.
Liability, in malpractice cases, 103, for negligence of hospital nurse, 22; of charitable hospitals, 148.
Libraries, medical, 329.
Library, medical of Atlantic County, 404.
License, practising suggestive therapeutics without, 188; practising without, 22, 569.
Licensing board, a national, 1072.
Life, conservation of, 763; expectancy and operations on gallbladder, 874; insurance of, see life insurance; lengthening of, with aid of life insurance experience, 367.
Life insurance, and alcoholism, 201; and approaching organic disease, 243; and breach of warranty, 115; and bronchial asthma, 410; and Christian Scientists, 874; and complications of infectious catarrhs, 874; and examination of the urine, 455; and general medicine, 829, and influenza, 916, 829; and medical selection, 746, 916, 957, 1001, 1041, 1082; and mouth and teeth, 115; and operations on gallbladder, 874; and overweights, 75; and pulse anomalies, 663; and the Copenhagen heart, 791; and the Wassermann reaction, 791, 201; and tuberculosis mortality, 705; build, and mortality, 34; director and his status in courts, 91; examinations, 160; examinations, danger signals in, 286; examinations, microscopy of urinary sediments in, 663; experience, application of, to lengthen life, 367; father as beneficiary in, 496; heredity and constitution, 582; history taking in, 91; medical investigations in, 327; medicine, 410; medicine and medicine as a whole, 705; sphygmomanometer in, 75; syphilis, and the Wassermann reaction, 327.
Light, mouth, electrical, 609; therapeutics of, in military medicine, 200.
Lipoma, extraperitoneal, 167.
Lips and cheek, epithelioma of, 77.
Lister, back to, 615.
Literature, medical, classification of, 940; medical, preparation of, 1019.
Lithotrite, visual, 187.
Liver, abscess, 120; fastening of, in hepatosis, 956; function, phenoltetrachlorphthalein test of, 1089.
London, J., a new visual lithotrite, 187.
Louse, clothes, warfare against, 366, 1081; plague among soldiers, 704; plague and prophylaxis of typhus, 1080; prophylaxis against, 745.
Louvain and its university, 110.
Luckett, W. H., a new instrument for scarifying in the von Pirquet cutaneous tuberculin test, 650.
Luetin and Wassermann tests at naval prison, 523.
Luke, H. C., a new gas-oxygen-ether apparatus; description and use of the instrument, 980.
Lungs, bayonet wounds of, 1000; wounds of, 409.
Lydston, G. F., a unique case of syphilis of the cranium and spine, with remarks on syphilitic bone dystrophy, 43; Dr. Lydston misquoted, 279.
Lymphangioma, 754.
Lymphosarcoma benzol in, 579.
Lynch, J. M., the infected colon and its surgery, 983.

M

McCaskey, D., what first aid in railway surgery does not mean, and what it actually does mean, 259.
McGurn, W. T., further remarks on the retention of salvarsan, 645.
McRobert, psychogenic convulsions, the result of a wish, 899.
McSweeny, E. S., are we getting proper value from our plant and expenditure for the tuberculous, 94.
MacRobert, R. G., the epileptic type of nervous constitution, 394.
Mabbott, J. M., some desultory personal observations on perineorrhaphy, puerperal septicemia, and pain, 308.
Macy, M. S., some observations on clinical treatment for systemic goiter (Graves' disease), 431; pituitary gland in gonorrheal arthritis, a report of three consecutive cases, 1024.
Malaria, and impounded water, 317; control of, 695.
Mallory, W. J., the present status of the diagnosis of cancer of the stomach, 1058.
Malpractice, action, statute of limitations in, 398; and emergency cases, 63; excessive, damages in, 1070; expert testimony in, 944; insufficient evidence as to, 230, 815; with respect to *x*-ray burn, 355; suits, defense of, by medical society, 733.

Malt soup in institution marasmus, 832.
Malta fever, chemotherapy of, 362.
Marcquis and Boudewyns, Drs., of Antwerp, 975.
Martin, W., blood pressure variations, with some reference to treatment, 269.
Marasmus, institution, malt soup in, 832.
Mastitis, in pregnancy, 71.
Maxilla, inferior, fractures of, 157.
Maybaum, J. L., diagnosis and conservative treatment of inflammation of the accessory sinuses of the nose, 1025.
Mayer, E., medical literature and its preparation, 1019.
Mayo, R. J., the fight against tuberculosis, 491.
Measles, immunization against, 752.
Measuring board for infants, 814.
Mediastinum, tumor of, 672.
Medical Society of the County of New York; address of president-elect, 498; address of retiring president, 498.
Medical Society of the State of New York, address of the president, 747; address of welcome, 750; discussion of president's recommendations, 748; election of officers, 750; oration on medicine, 750; report of committee on expert testimony, 748; report of committee on legislation, 749; report of committee on medical legislation, 749; report of committee on medical research, 749; report of committee on midwives, 749; report of committee on public health, 748; report of committee on publication, 748; report of counsel, 749; report of the secretary, 748; report of the treasurer, 748; report of workmen's compensation committee, 749; Section on Syphilis discontinued, 750; shall American Medical Association have appellate jurisdiction, 750.
Medicine, a neglected field of culture in, 349; agreements not to practise, 272; America's supremacy in, 273; and Rabelais, 595; clinical, and blood pressure, 1003; literature of, 1019; of the Old Testament, 934; patent, 739; practice of, and title of statute, 398; practising, without authority, 815; progress of, and animal experimentation, 779; scholarship in, 281.
Mellon, R. R., the early diagnosis of streptococcic sore throat and the effect of vaccines in its treatment, 809.
Meningitis, 740; a new treatment of (use of soamin), 535; and the sphenoidal sinus, 998; meningococcus in, 660; newer conceptions of, 611; serum and vaccine treatment of, 408; serum, effects of, 625; suppurative arthritis in, 1069; tuberculous, new method of treatment of, 580.
Meningococcus, in meningitis, 660; in peripheral blood, 743; varieties of, 624.
Menorrhagia, uterine fibroids and radium, 379.
Menthol-eucalyptol treatment of pneumonia, pleurisy, and bronchitis, 200.
Mercury, bichloride poisoning, treatment of, 1006; deep muscular injections of, in treatment of pyorrhea alveolaris, 424.
Mesentery, tumor of, 587.
Metacarpal, cyst of, 71; sarcoma of, 77.
Meyers, J., the diagnosis and treatment of cancer of the stomach, with a suggestion as to possible racial treatment of cancer, 848.
Michie, H. C., Jr., Mexican typhus fever, 214.
Microscope, localization in, 672.
Migraine, glyceryl trinitrate in, 420; ophthalmic, treatment of, 420.
Migrants, tuberculosis of, 1044.
Military training, effect of, upon lead workers, 1076.
Milk, modification, cereals in, 396; pasteurized, *Bacillus coli* in, 741.
Mind, defect of, borderland cases of, 700; deficiency of, and State policy, 665, 671; disease of, see, immunity; limitations of, of the precox type, early recognition of, 894; periodic depressions of, 335; pathology of, 31, 72, 112; unconscious phenomena of, 348.
Moffett, R. D., a new baby bottle, 442; a new measuring board for infants, 814.
Mole, hydatid, with cancer of vulva and vagina, 165.
Monsters, 1007.
Montgomery, D. W., the influence of the study of medicine on Rabelais, 595.
Morphine, action of, 1100.
Morris, R. T., Freud from a surgeon's viewpoint, 841; what do we mean by the unfit, 135.
Mortality, build and, 34; institutional, of the newborn, 240.
Morton, W. J., radiochemicotherapy; the internal therapeutics of the radio-elements, 381.
Moschcowitz, H. V., the relation of hernia to the workmen's compensation law, 547.
Mosenthal, H. O., the treatment of diabetes mellitus in dispensaries, 589.
Mould diseases, 312.
Mount, L. B., the alopecias, 852.
Mouth, infection and systemic disease, 797; infection and vaccines, 91; sepsis, 618; writing for the armless, 999.
Mucklow, A. E., a method of feeding infants with precision, 295.
Müller, R. W., the Nggelschmidt modification of the Kromayer quartz lamp in the treatment of diseases of the hair and scalp, 773.
Mumps, and atrophy of prostate, 404; deafness following, 353.
Muscle, chronic contractions of, 963; extensor longus pollicis, rupture of, 659; strength, clinical instrument for measuring, 83.
Mushroom poisoning, 703.
Myeloma, multiple, 204.
Myocardium, see heart muscle.
Myositis, gluteal, 1064; ossificans traumatica, 1093.
Myxedema simulating nephritis, 869.

N

Narcosis, asphyxia after laparotomy, 242; suggestion, 1069.
Narcotics, addiction to, 247; law against, 274.
Nasolabial area, gray hair, and disease in, 158.
Nasopharynx, fibroma of, effects of radioactivity upon, 1056.
Nauheim baths in the United States, 972.
Navy, surgeon-general of, report of, 24.
Needles, locating of, in tissues, 450.
Negligence liability of private hospital for, 777; of physician or surgeon, 902; of nurses, liability of private hospitals for, 650.
Nephrectomy, procedures following, 578.
Nephritis, drug treatment of, 1008.
Nephrolithiasis, 869.
Nerve, alcoholic injection of, 1037; concussion from bullet and shell wounds, 198; peripheral, regeneration of, 963; superior laryngeal, alcohol injection of, 239; ulnar, scar tension on, 658; shot wounds of, 704.
Nervous system, central, intraspinal treatment of syphilis of, 472; constitution, of epileptic type of, 394; disorders of, in children, 320; in naval warfare, 316; in primary syphilis, 579; sympathetic and the gastroenteric function, 127; syphilis of, treated with salvarsan, 251; wounds of, in war, 238.
Neuralgia, and neuritis, treated with bacterial toxins, 73; trigeminal, treatment of, 504.
Neurasthenia, among garment workers, 292.
Neuritis, and neuralgia, treated with bacterial toxins, 713; lead, from cosmetics, 870; multiple, astasia-abasia in, 71; optic, 605; optic, due to sphenoidal sinusitis, 241.
Neurology, war, 113.
Neurosis, psychopathology of, 787; tic, 171; traumatic, and war, 744.
New York Academy of Medicine: address of incoming president, 245; address of retiring president, 245; report of board of trustees and treasurer, 245; report of public health, hospital, and budget committee, 245; resolution, 245.
New York Psychiatrical Society, report of committee on legislation of, 334, 670; report of committee on national hygiene movement, 335.
News, medical, in *New York Times*, 403.
Nicholson, P., the clinical significance of blood pressure, 473.
Nipples, sore and fissured, treatment of, 840.
Nixon, P. I., non-bacterial urethritis, 607.
Noguchi, H., propagation of pure vaccine virus, 717.
Nose, accessory sinuses of, a new nonoperative treatment of, diseases of, 546; accessory sinusses of, diagnosis and conservative treatment of inflammation of, 1025; deformity of, from submucous operation, 813; diseases of, and headache, 533; diseases of, *x*-ray prevention of, 532; plastic operation on, 921; septum of, deflection of, 762; tuberculosis of, 147.
Nostrums, itinerant vendors of, 103.
Noyes, W. B., studies of atypical children; from the department of ungraded classes in the public schools of New York City, 885.
Nutrition, and growth, 870; economy in, 495.
Nuts and fruits in children's diet, 834.
Nystagmus, miner's, in the trenches, 153.

O

Obesity, ergotherapy in, 725; general faradization (Bergonié) in treatment of, 501; treatment of, 123, 186.

Sterility caused by *x*-ray, 776.
Stern, S., deep Roentgen therapy and its application in the treatment of malignant growths, 221.
Stomach and duodenum, benign lesions of, late results of, 1092; and duodenum, ulcer of, in infancy and childhood, 989; and jejunum, ulcers of, 1092; cancer of, 407; cancer of, diagnosis and treatment, 848; cancer of, early recognition of, 796; cancer of, familial, 837; cancer of, in a boy of nine, 828; carcinoma of, 1007; contents, analysis, 826; contents, mucous membrane in, 1078; chronic dilatation of, 718; disorder caused by obstruction of ileum, 795; passage of liquors from, 617; resection of, after fasting, 672; secretion and bitter tonics, 12; symptoms and surgical intervention, 796; syphilis of, 421; ulcer and cancer of, relation between, 1092; ulcer of, 826; ulcer of, and focal infection, 797; ulcer of, chronic, 1092; ulcer of, infective localization of streptococci in, 959; ulcer of, etiology of, 817; ulcer of, pathogenesis of, 275; ulcer of, pylorectomy for, 204; ulcer of, treatment of, 913; vertigo, treatment of, 840.
Stomachic for children, 546.
Stools, in infancy, examination of, 1091.
Strauss, I., treatment of sciatica by epidural injection of saline solution, 213.
Streptococcus, peril, 184.
Strachstein, A., two causes of persistency and incurability of certain affections of the genitourinary tract, 909.
Straw powder as food and fodder, 828.
Street conditions, 952.
Streptococci, elective localization of, 959.
Stransky, M., neglected lateral curvature, 430.
Study, economy in, 934.
Suicide and insomnia, 31.
Suprarenal glands, extract of, and infancy, 42; in delirium tremens, 31; in shock, 404.
Surgeons, trials and principles of, 701.
Surgery, a curiosity of, 534; bone, misapplied, 669; in war, 74; orthopedic treatment of, 668; railway, first aid in, 259.
Swanberg, H., the intervertebral foramina in man, 176.
Symmetromania, 714.
Synnott, M. J., the intraspinal treatment of syphilis of the central nervous system, 472.
Syphilis, 689; a new reaction in, 407; as cause of feeblemindedness, 836; and yaws, 151; cerebrospinal, mercurialized serum treatment of, 30; conjugal, 850; heart in, 879; hereditary, later manifestations, 835; involving nervous system in its primary stage, 579; involving thalamus, 83; Landau's color reaction in, 825, 1079; masked cure of, 780; menace of, 659; of arteries and veins, 877; of cranium and spine, 43; of central nervous system, intraspinal treatment of, 472; of nervous system treated with salvarsan, 251; of stomach, 421; parenchymatous, 365; pathology of, 876; psychical aspect of, 111; recent studies of, 1051; therapy of, 344; visceral, 242; Wassermann reaction, and life insurance, 327; *x*-ray diagnosis of, bone lesions in, 836.

T

Tabes, ataxia of, 701; crises of, 543; gastric and pain crises in, 824; treatment of pains of, 546, 840, 966.
Taboparesis, syphilis contagium in, 242.
Teeth, osteitis about, in relation to arthritis, 426.
Telephone attachment in surgery, 324.
Temperature, subnormal, in tuberculosis, 110.
Tendon reflex threshold, instruments for measuring, 83.
Testimony of physician, scope of, 442.
Tetanus, 69, 242, 113, 158, 620, and antitetanic serum, 870; carbolic acid treatment of, 112; colloidal iodine and serum treatment in, 533; diagnosis and treatment, 457; in European war, 105, in war, 743, 744; in wounded soldiers, 325; indirect mortality from, 401; lateralis, 955; magnesium sulphate treatment of, 114, 741, 1006; modification of Baccilli's method in, 504; neonatorum, 1073; odd aspects of, 294; prophylaxis of, 200, 534; serum intoxication, 285; treated by light, 661; treated with antitoxin given intraspinally, 1005; treated with flooding with antitoxin, 232; treatment of, 32, 33, 326, 535; 580, treatment of, in Germany, 238.
Thalamus, lesion of, 543; syphilis involving, 83.
Thermometer, homograde, 25, 859.
Thomas, G. E., results of Wassermann and luetin tests at the naval prison, Portsmouth, N. H., 523.
Therapy, psychic, 680.
Thorax, and abdomen, acute diseases of, 789; tumors within, diagnosed by exploratory puncture, 711.
Thorium-X, biological action of, 990.
Throat, streptococcic, 809.
Thromboangeitis obliterans, arteriovenous anastomosis for, 332.
Thrombopenia, essential, 1039.
Thrombosis, extravascular, 734.
Thymus, hypertrophy of, and thymus death, 924; roentgenization of, in Graves' disease, 788.
Thyroid, diseases, diagnosis and surgical treatment of, 374; excessive activity of, 877, 878; functions and thyrogenic disease, 999; in insanity, 1035; intoxication from, and high blood pressure, 1007; iodine containing compound of, 1007; pathology and iodine compounds of, 1007.
Tibiæ, deformities of, 995.
Tic, convulsif, treated with calcium chloride, 73; neurosis, 171.
Tissue extract as a hemostatic, 788.
a hemostatic, 787.
Tongue, excision for carcinoma, 120; tuberculosis of, 71.
Tonsil and adenoid operations, appliance for suction and pressure in, 732.
Tonsils, and tuberculous glands, 155; infections of, 954, 998.
Toothache drops, 623.
Towel, sanitary study of, 672.
Trachoma increasing, 190.
Transfusion, 162; by gravitation method, 354; cannula and needle for, 482; clinical studies in, 1004; in treatment of pernicious anemia, 163; in treatment of purpura, chronic sepsis, 410; in treatment of splenomegalic anemia, 331; new method of, 141; of citrated blood, 448; of citrated blood, simple syringe method for, 440; simple method of, 707; simplified method of, 195.
Transplantation of organs and ferments of blood, 79.
Trichomoniasis of intestine, 824.
Trypanosomes, transmission of, 1046.
Tubercle bacillus, effect of daylight and drying on, 241; in urine, 533.
Tuberculin, administration and graduated labor, 954; in pulmonary tuberculosis, 161; skin reactions in children, 321; therapy, 306.
Tuberculosis, and contraception, 1077; and gout, 570; and poverty, 66; and warfare, 285; calcium and parathyroid medication in, 672; chemotherapy of, 694; experimental role of lymphocytes in, 626; fight against, 356; immunization against, 127; in children, treatment of, 924; in lepers, 657; infection with, among children of New York tenements, 417; localized, treatment of, 611; nasal, 147; of hip, 953; of larynx, treatment of, 814; of tongue, 71; of migrants, 1044; prevention and treatment of, 227; preventorium for children, 947; prophylactic inoculation, against, 743; psychology of the victim of, 310; self-drugging in, 117; small heart in, 741; spread of, 232; subnormal temperature in, 110; surgical, Rollier treatment of, 834; traumatism in relation to, 1038.
Tumors, chemotherapy of, 741; role of worms and protozoa in etiology of, 490; tissue of, cultivation of, 491.
Twilight sleep, 55, 363, 756; in home, 146; observations on, 715; see also anesthesia and scapolamine.
Typhoid fever, abortion of, 476; abscess formation in, 1038; and paratyphoid fever differentiated, 450; and paratyphoid fever, inoculation against, 408; alcoholic stimulation in, 840; autogenous living vaccines in, 704; crisis in, 30; diagnosis of, on the

field, 191; following antityphoid inoculation, 199; hemorrhage symptoms, 828; in the German army, 662; inoculation against, 111, 405, 872; inoculation against, and the Widal test, 526; mobilization, 150; new therapeutic measures in, 485; sensitized vaccines in, 323; spondylitis of, 955; treatment of intestinal hemorrhage in, 882; with typhoid pneumonia and pulmonary abscess, 539.
Typhus fever, 444, 789, 983; Mexican, 214; prophylaxis and the louse plague, 1080; simulated by meningitis, 612; vaccine, 655.
Tyrosine and the origin of living organisms, 1034.

U

Ulcers, skin grafts in ambulatory treatment of, 364; tuberculous, new treatment for, 252.
Umbilical cord, non-ligation of, 581.
Unfit, meaning of, 135.
Urea, excretion of, 624.
Uremia, 915; conceptions of, 863; toxic substance from blood in, 1006.
Ureter and kidneys, anomalies of, 164.
Urethra, caruncle of, 1035; clamp for, for postoperative urinary incontinence, 814; prostatic, rupture of, 776.
Urethritis, non-bacterial, 607.
Uricometer, clinical, 542.
Urine, examination in life insurance, 455; in old age, 323; nervous retention of, 1; ureteory mechanism of, 104; tubercle bacilli in, 533.
Urticaria, a lotion for, 630; a powder for, 252.
Uterus, adenocarcinoma of, 586; anteposed, treatment of, 155; bicornis unicollis, pregnant, 168; bleeding from, pituitary extract in, 226; bleeding from, and adenosclerosis, 913; enormous tumor of, 62; fibroids of, menorrhagia, and radium, 379; physiology and pharmacology of, 119; postpartum retrodisplacement of, 825; traumatic displacement of, 587.

V

Vaccination, antagonism against, in disguise, 231; compulsory, of school children, 777.
Vaccine, mixed typhoid, partyphoid A, and paratyphoid B, 871; treated with ether, 326; treatment of pneumonia, 69; treatment of typhoid fever, 860; typhus, 654; virus, pure, propagation of, 717.
Vaccines, and mouth infection, 91; autogenous, in pneumonia, 753; autogenous living, in typhoid fever, 704; in pertussis, 952; in streptococcic sore throat, 809; increasing efficiency of, 436; sensitized, in typhoid fever, 323.
Vagotonia, case of, 412.
Valve, mitral, rupture of, 618.
Varicella, with two eruptive stages, 683.
Varicocele operation, a new incision for, 355.
Veins, distention of, for intravenous injections, 1030; syphilis of, 877.
Venereal disease, and prostitution, 363; in the army, 413; in war, 736; prevalence of, 653.
Venoms, animal, 1073.
Vertebral column, see spinal column.
Vertigo, gastric, treatment of, 840
Verumontanum, radial removal of, 112.
Vesaliana, 247.
Vesalius, and the spirit of his time, 245; anatomical illustrations before and after, 246; portraits of, 246; quadricentennial in Berlin, 275; the spirit of, 110.
Vision, color, and color blindness, 112; defect of, in recruits, 999.
Vitamine theory, extension of, 778.
Voice troubles in singers, 757.
Volkmann's contracture and fractures about elbow, 652.
Vomiting, in infants, treatment, 882.
Von der Osten, a logical classification of medical literature, 940.
Von Mayer and the conservation of energy, 274.
Von Pirquet test, 57; scarifier for, 650.
Von Rueck, S. H., prophylactic and therapeutic immunization against tuberculosis; its possibilities and limitations, 137.
Von Wedekind, L. L., the general use of distilled water, thereby securing the elimination of toxins leading to arterial changes and the elimination of water-borne disease, 59.
Voorhees, I. W., some common voice troubles in singers, 757.

W

War, amputations in, 157; and anthrax, 158; and artificial solar therapeutics, 200; and cardiovascular disease, 200; and disease, 279; and food, 827; and forensic medicine, 158; and sexual life, 324, 365, 409, 453; and typhoid fever, 150; as studied by German surgeon through hostile and neutral medical journals, 790; brides, illegitimacy and legalized abortion, 816; feeding of people during, 159; hospitals, letters from, 158; medicine experience in England and France, 620; injuries from cold in, 113; memorable field day in, 294; neurology, 113; notes, 153; preparation of American profession for, 904; psychology of, 111; psychopathology of, 110; surgical experiences in, 74; to deaden sound of, 462; wounds of, see wounds.
Wassermann reaction, and life insurance, 201, 791; and luetin reaction at naval prison, 523; clinical features of, 493; contradictory findings in, 734; discrepancies in, 61; in ophthalmology, 452; syphilis and life insurance, 327.
Watch, wrist, dangers of, in warfare, 462.
Water, chemical disinfection of, 274; distilled, general use of, 59; meal, clinical use of, 1077; rapid sterilization of, 546; supplies, hypochlorite treatment of, 653.
Waters, B. H., an experimental study of a new remedial agent and of its effects in pulmonary tuberculosis, 263.
Watkins, V. E., history of a case of Jacksonian epilepsy, 1068.
Weight excessive, in life insurance, 75.
Weil, R., medical news in the "New York Times," 403.
Weinstein, J., a clinical report of the successful use of emetine in the control of hemorrhage following nasopharyngeal operations, 102; deafness following mumps, 373.
White, P. G., the treatment of pyorrhea alveolaris and its secondary systemic infections by deep muscular injections of mercury, 424.
Whitman, A., two months' service in a small hospital, 480.
Whooping cough, see pertussis.
Widal test, and antityphoid inoculation, 526.
Wight, J. S., a new method of increasing the efficiency of vaccines and of producing antisera, 436.
Wile, I. S., chronic diseases of the heart, kidneys, and arteries from the standpoint of etiology, prevalence, mortality, and prevention; a detailed plan for public education in a large city looking toward the prevention and control of these diseases, 926.
Williams, B. G. R., some peculiar mould diseases, 312.
Williams, C. M., recent advances in dermatology and syphilography, 1051.
Williams, L. R., a warning, 656.
Williams, T. A., the treatment of epilepsy from metabolic disturbances in adolescence, 772.
Wolbarst, A. L., a urethral clamp for postoperative urinary incontinence, devised and made by a patient for his personal use, 814.
Woman, suffrage and biological differences in the sexes, 861; diseases of, occupational factor in, 97.
Words, use of, 1089.
Wounds, antiseptic pastes in treatment of, 526; antiseptic treatment of, 579, 615; bayonet, of lungs, 1000; caused by indirect projectiles, 73; firearm, 237; from airman's dart, 238, 535; from French projectiles, 21; from indirect projectiles, 284; gangrenous, treated with artificial gastric juice, 445; gunshot, 793; gunshot and shell, 826; gunshot, of abdomen, 158; gunshot, of head, 452; gunshot, of skull, 581; in war, 530, 867, 912; in war, treatment of, 754, 914; infected, open treatment of, 997; infected, treated by iodized carbon, 613; infections of, 742, 783, 788, 826, 871; inflammation of, treatment of, 1039; permanganates in, 72; of chest, 1000; of lung, 409; of nerves, 704; self-contaminated, 579.
Wounded, exposition on care of, 490; psychology of, 744.
Wright, B. L., the treatment of pyorrhea alveolaris and its secondary systemic infections by deep muscular injections of mercury, 424.

X

X-ray, and military surgery, 361; application to thymus in Graves' disease, 788; diagnosis of bone lesions in syphilis, 836; examination of alimentary canal, standard meal for, 867; filtered, in treatment of eczema, 1040; in deep-seated cancer, 825; localization of foreign bodies, 158; pictures, demonstration of, 961; prevention of nasal disorders, 532; sterility caused by, 776; therapy, deep, in treatment of cancer, 221; treatment of cancer, 145; treatment of eczema, 523.

Y

Yaws and syphilis, 151.

Z

Zingher, A., a simple syringe method for the transfusion of citrated blood in children, 440.
